writing clerks and dictaphones to mitigate the labors of record keeping. It would be interesting to know what impression the great American surgeon formed from his intimate visit here. At all events, he has left a pleasant impression behind him.—*The Lancet*, 17th June, 1922.

WEEK'S DEATH RATE IN BOSTON.—During the week ending Aug. 19, 1922, the number of deaths reported was 196, against 194 last year, with a rate of 13.38. There were 40 deaths under one year of age, against 32 last year.

The number of cases of principal reportable diseases were: diphtheria, 66; scarlet fever, 12; measles, 24; whooping cough, 29; typhoid fever, 4; tuberculosis, 31.

Included in the above, were the following cases of non-residents: diphtheria, 4; scarlet fever, 4; typhoid fever, 1; tuberculosis, 9.

Total deaths from these diseases were: diphtheria, 5; scarlet fever, 1; measles, 2; whooping cough, 2; tuberculosis, 13.

Included in the above, were the following cases of non-residents: diphtheria, 1; tuberculosis, 1.

THE HEALTH ACTIVITIES OF THE UNITED STATES BUREAU OF MINES.—This report outlines the history and development of the Bureau, its legal authority, organization, personnel, appropriations and cooperation with other agencies. The report is the ninth in a series concerning those activities of the U. S. Government which deal directly or indirectly with the public health. The previous reports of the Council include, the Division of Vital Statistics of the U. S. Bureau of the Census; the Children's Bureau of the U. S. Department of Labor; the Women's Bureau of the U. S. Department of Labor; the Government Health Activities (with a chart); the Division of School Hygiene of the U. S. Bureau of Education; the Health Section of the Bureau of Indian Affairs of the Department of Interior; the Division of Welfare of the U. S. Post Office Department; and the Bureau of Animal Industry. It is planned in the near future to combine all of these reports in a single printed pamphlet, thus offering for the first time correlated, accurate and impartial data concerning the public health work of the Government. The National Health Council is a confederation of the fourteen leading national voluntary health organizations of the country, and has offices in New York and Washington. Copies of the Bureau of Mines Report or of any of the others may be obtained without charge from James A. Tobey, Washington Representative of the National Health Council, 17th and D Streets, N. W., Washington, D. C.

THE nineteenth annual meeting of the British Medical Association was held in Glasgow, Scotland, from July 25 to 28, under the presidency of Dr. David Drummond, of Newcastle-on-Tyne. Sir William Macewen, Glasgow, was elected president for the year 1922-1923. Mr. Charles P. Childe, Southsea, is president-elect for the annual meeting to be held in Portsmouth in 1923.

DR. FREDERICK ROBERT ZEIT, for more than twenty years professor of pathology at Northwestern University Medical School, at his request has been relieved of active duty in the medical school. He plans to spend next year abroad. The pathological museum of the university will hereafter be known as the Frederick Robert Zeit Museum of Pathology.

DR. GEORGE MILBRY GOULD, known for his work in medical ophthalmology and especially in eyestrain, formerly editor of *American Medicine*, *Biographic Clinics* and the Gould Medical Dictionary, died on August 8, aged seventy-four years.

THE third International Congress of the History of Medicine was opened on July 17, at the Royal Society of Medicine, London. Dr. Charles Singer, lecturer on the history of medicine, London University, presided. The following countries were represented: Belgium, Czechoslovakia, Denmark, Egypt, France, Greece, Holland, Italy, Portugal, Rumania, Spain, Switzerland and the United States. Lord Onslow, parliamentary secretary to the Ministry of Health, welcomed the delegates on behalf of the government, after which Dr. Singer addressed the congress. Dr. Laignel-Lavastine acknowledged the welcome on behalf of the foreign delegates.

MISSION and educational bodies of East China have set in motion a project to build in Shanghai a union medical school at a cost of \$500,000. St. John's University of Shanghai, which now has a medical department, is one of the institutions supporting the project.

CHANGE OF OFFICE.—Dr. David D. Scannell has removed his office to 320 Commonwealth Avenue, Boston.

Miscellany.

LEGISLATIVE MATTERS

The National Health Council in its report covering August 1-14, relating to legislation contains the following:

The Tariff and Public Health. H. R. 7456.

The fixing of the final vote on the Tariff Bill

on August 19th, brings up the question as to what will be done on the embargo provisions therein relating to dyes and the related synthetic drug industry. Before the War the United States produced none of these materials and all came from the German chemical sources. Due to necessities created by the War, several hundred plants and laboratories have developed in America, producing Salvarsan, Cinchophen, and Novacaine and other important medicinals. On a recent vote the Senate refused to retain the present embargo against the importation of such products. The medical fraternity throughout the country, and also chemists and laboratories, are demanding that Senators reverse their vote and continue the embargo. A second vote will be had. If the embargo is not retained it is claimed that at least two hundred laboratories and plants producing synthetic medicines will not be able hereafter to meet competition from German sources which will have entry into the United States."

H. R. 4.

"This bill, which passed the House on February 1, 1922, and passed the Senate, August 3, 1922, grants pensions to army nurses who served under contract with the Army during the War with Spain, Philippine Insurrection, or Chinese Boxer campaign for 90 days, or who were disabled and released prior to 90 days' service.

"When the Army Nurses Corps was first organized in 1898, nurses were employed under contract by the Surgeon-General of the Army. Under the existing Army Reorganization Law of February 2, 1901, nurses are given a military status from and after that date. The present law extends this recognition so as to give a military status to Army Nurses beginning with the Spanish War and running to February 2, 1901. The effect of this bill will be to give women who served as nurses the exact pension allowances that are awarded to soldiers in the War with Spain, etc., under the act of June 5, 1920."

AMERICAN RELIEF ADMINISTRATION.

Moscow, July 13.—If medicine could cure the body politic, Russia by now ought to be on a fair way to recovery. The American Relief Administration is pouring medicine into the Soviet Republic, not by the teaspoonful, but by the ton.

If purgation has a corresponding effect upon Russian red that fiery hue ought soon to be reduced to at least a pale pink, for one of the items on the list of surplus army medical supplies sent to Russia is 52,000 pounds of Epsom salts. No one who served with the A. E. F. in France would quite believe it possible considering the number of "C. C." pills consumed by the American Army, but it is a fact that the

surplus sent to Russia is 50,000,000. Epsom salts used with discretion yield some 64 doses to the pound. Fifty-two thousand pounds of Epsom salts would mean 3,328,000 doses. Castor oil is another big item on the laxative list, and there are others.

The quantities are stupendous, but so is the need. Hospital after hospital, dispensary after dispensary has found itself unable to compound the simplest prescriptions because of the lack of many common and generally used pharmaceutical preparations.

Malaria, which is becoming increasingly prevalent in Russia, has raged practically unchecked because quinine was almost unobtainable. America's contribution of quinine is 20,000 pounds.

If Russia should cut its finger there would be no immediate lack of dressings. In the first place, if the cut is not a serious one, there are 80,000 bottles of collodion, to be applied after half a million tubes of iodine had been used to cleanse the wound, and 1,200,000 iodine swabs had been used to wipe it out. If it were more serious, there would be bandages enough and to spare. The A. R. A. has received for distribution 21,600,000 plain gauze bandages and more than 6,000,000 yards of compressed gauze bandages and over half a million pounds of cotton.

The A. R. A. order for neo-salvarsan, which is regarded as a perfect specific for typhus recurrens as well as for syphilis, to date totals nearly half a million tubes.

In addition to the soap distributed through the regular channels in connection with child feeding and general relief, the medical department of the A. R. A. has had close to 1,000,000 pounds to give out to hospitals, homes and institutions.

The 400,000 pounds of sulphur is being distributed.

RÉSUMÉ OF COMMUNICABLE DISEASES JULY, 1922.

GENERAL PREVALENCE.

There were 4,097 cases of communicable disease reported during July—2,734 less than the total for the previous month. The decrease was noted in all of the more common communicable diseases, with the exception of whooping cough, and is the usual decrease for this season.

Anterior Poliomyelitis.—There were 23 cases of this disease reported during July. This shows the usual increase during the month of July, but does not equal the total of 26 cases obtained during July, 1921. The cases as reported are scattered throughout the eastern

section of the State, the only city showing an unusual number of cases being New Bedford, with a total of 7.

Chicken-pox was reported in 136 instances, a sharp drop from 325 cases reported during June.

Diphtheria shows a slight decrease from 459 cases reported during June, the month's total being 381. This disease continues to be reported in slightly fewer numbers than last year.

Encephalitis lethargica was reported in 6 instances.

Epidemic cerebrospinal meningitis was reported but once during the month. While a falling off in the number of cases is usually noted during the summer months, this low figure has not been reached for several years.

Gonorrhea and *syphilis* were reported in 407 and 155 cases, respectively.

Malaria was reported in 8 instances, an increased number of reports to be received.

Measles continues to be reported in large numbers, 1,275 reports being received, as compared with 866 for the same month of last year. This, however, is a decided decrease from the 3198 cases reported during June.

Mumps is also showing a decrease in reports received, dropping from 375 cases in June to a total of 184 in July.

Scarlet fever was reported in 226 instances, about the average for this month.

There were 506 cases of *pulmonary tuberculosis* and 69 cases of *tuberculosis, other forms*, reported. This is a decrease from the previous month.

Typhoid fever increased from 41 cases in June to 74 in July. The only communities showing an unusual incidence were Worcester, with 10 cases, and Montague, with 3 cases.

Whooping cough increased in the number of cases reported to 413. While an increase of 54 over the previous month is not unusual, it is conspicuous because this is the only one of the so-called common diseases which has increased rather than decreased during the month.

RARE DISEASES.

Influenza was reported from Attleboro, 1; Boston, 2; Brookline, 1; Cambridge, 1; Clinton, 1; Fall River, 1; Haverhill, 1; Lawrence, 1; Medford, 1; Methuen, 1; New Bedford, 7; Revere, 1; Somerville, 2; Uxbridge, 1; Westfield, 1; total, 23.

Dysentery requiring *antibiotic treatment* was reported from Barnstable, 2; Boston, 9; Cambridge, 1; Chelmsford, 3; Georgetown, 1; Holyoke, 1; Lowell, 15; Medford, 1; Plymouth, 1; Springfield, 1; Wellesley, 1; Weston, 1; Worcester, 1; total, 41.

Encephalitis lethargica was reported from

Boston, 2; Cambridge, 1; Peabody, 1; Springfield, 1; Worcester, 1; total, 6.

Epidemic cerebrospinal meningitis was reported from Fall River, 1.

Hookworm was reported from Boston, 2.

Malaria was reported from Boston, 2; Fall River, 1; Haverhill, 1; Milford, 3; Northampton, 1; total, 8.

Pellagra was reported from Northampton, 1.

Septic sore throat was reported from Boston, 2; Fall River, 1; Leominster, 1; Norwood, 1; Springfield, 1; Whitman, 1; total, 7.

Tetanus was reported from Fall River, 1.

Trachoma was reported from Boston, 4; Fall River, 1; Fitchburg, 1; Lowell, 1; Somerville, 1; total, 8.

DISTRIBUTION.

All communicable diseases: Total cases (all causes) for July, 1922, 4,097; for July, 1921, 3,989. Case rate per 100,000 population for July, 1922, 104.1; for July, 1921, 102.2.

Certain prevalent diseases: *Diphtheria*—Total cases for July, 1922, 381; for July, 1921, 441. Case rate per 100,000 population for July, 1922, 9.7; for July, 1921, 11.3. *Measles*—Total cases for July, 1922, 1,275; for July, 1921, 866. Case rate per 100,000 population for July, 1922, 32.4; for July, 1921, 22.2. *Scarlet fever*—Total cases for July, 1922, 226; for July, 1921, 251. Case rate per 100,000 population for July, 1922, 5.7; for July, 1921, 6.4. *Typhoid fever*—Total cases for July, 1922, 74; for July, 1921, 62. Case rate per 100,000 population for July, 1922, 1.9; for July, 1921, 1.6. *Whooping cough*—Total cases for July, 1922, 413; for July, 1921, 474. Case rate per 100,000 population for July, 1922, 10.5; for July, 1921, 12.1. *Tuberculosis, pulmonary*—Total cases for July, 1922, 506; for July, 1921, 479. Case rate per 100,000 population for July, 1922, 12.9; for July, 1921, 12.3. *Tuberculosis, other forms*—Total cases for July, 1922, 69; for July, 1921, 55. Case rate per 100,000 population for July, 1922, 1.8; for July, 1921, 1.4.

Correspondence.

INSTITUTE OF PREVENTIVE MEDICINE

Mr. Editor:

I am enclosing a free translation of an article by Professor Laurent of Nice, which was read before the Paris Academy of Medicine, in view of the interest now taken in arranging a National Health Examination Day, this added proof of the acceptance by progressive medical men throughout the world of this principle of periodic examination is important.

Yours very truly,

EUGENE L. FISK, M.D.
Medical Director, Life Extension Institute, Inc.,
25 West Forty-Fifth Street, New York.

Translation.

THE INDIVIDUAL HEALTH RECORD AND THE INSTITUTE OF PREVENTIVE MEDICINE. BY PROFESSOR O. LAURENT, OF NIE.

Correspondance Member of the Paris Academy of Medicine; Laureate of the Paris Academy of Sciences; Ex-Major (1st class) of the French Army; Honorary Member of the Academy of Medicine of Rio-de-Janeiro.

(The Bulletin of the Academy of Medicine, Paris, No. 24, June 13, 1922.)

THERE are two provinces of medicine, therapeutic and preventive. The latter, until recently given very little attention, is assuming an importance equal to that of the former, to the extent even that its services are becoming invaluable. Can one compute approximately the number of deaths from typhoid fever avoided during the war, and the number of complications that the epidemics of that disease would have caused, depreciating the life cycle? However, if the length of life has thus increased on the whole, the principal factor in this change is the lowering of infant mortality, so that we may say that the adult still actually remains insufficiently protected against menacing disease (the causes of morbidity-mortality being: toxemias, physical and psychical traumas and apathies, food deficiency and hormone deficiency) for, in spite of numerous efforts on every side, except when forced to do so, it is quite exceptional that man has himself medically examined solely for the purpose of finding out his physical condition, to perfect his hygiene, and to avoid illness. On the other hand, the examination taken solely for the purpose of conserving one's health, ought to be made under certain conditions, if it is to become universal and answer to all the desiderata of science.

There is need to establish a suitable organization with co-ordinated activities.

The Institute of Preventive Medicine, of the conservation of health, of the prevention of sickness, would comprise regional centres for the periodic physico-chemical examination, very easy of access, available to every adult, not ill, affiliating himself with the Association. The realization of this work would be easy because there exist in all the French towns x-ray and chemical laboratories, and the expense that they would incur would be covered by the thousands of individual or collective (industrial workers) subscribers.

Specialists should therefore form themselves into regional groups for the biological physico-chemical examination at the disposition of the member, for whom they will make out a balance-sheet of the complete physical condition, and to whom they will give a health bulletin together with general necessary counsel, especially with regard to hygiene, but without interfering in any way with the diagnostic clinic and with treatment.

These centres of physical examination would be connected with the General Committee, from which they would receive directions and which would have its journal. For propaganda they would rely upon the medical profession and the Red Cross; it could be associated with other works, anti-cancerous and anti-tuberculous, so beneficial to the public.

The health examination would often show up the functional troubles which are predecessors of definite ills, as well as a number of latent ills which are advancing towards the stage of gravity. How many men and women reach the age of 50 without ever having undergone a complete examination, afflicted however for some time with diseases of the heart, the blood vessels and the kidneys, or with various diseases already in an advanced stage! The general practitioner every day deplores the consequences of negligence, ignorance, quackery, prejudice, which only too often prove to be fatal. A great blank to make good!

In the United States the Life Extension Institute, which was organized years ago under the chairmanship of Mr. Taft, former president of the Republic,

comprises 7,000 physicians who have examined 250,000 people. (The privilege is extended to more than 600,000 insurance policyholders.) Dr. Eugene Lyman Fisk, Medical Director of the Institute, has published a number of works on this question; in collaboration with Professor Irving Fisher he is the author of the book, "How to Live," 25,000,000 in the working classes have mouth infection or defective teeth. It is reckoned that 80 per cent. of the deaths among adults (through infections of the heart, blood vessels or genito-urinary organs) could have been postponed for periods ranging from a few days to several years. And if this year 750,000 people are going to die from preventable diseases, we may conclude that France this year will suffer the loss of 200,000 in this way.

Intended principally for people who have reached the age of 40 and are physically fit, or believe themselves to be so, the physico-medical examination will bear principally on the condition of the heart, the blood pressure, the blood and the urine, but it will be absolutely complete and will take up scientifically the condition of all the organs.

Thus medical science, comprehensive as it is, the Encyclopaedia of Practical Medicine, would constantly be able to penetrate into the smallest corner of Brittany or of Savoy, as well as it can in the Paris hospital. The member would have not only the best chances of conserving his health and lengthening his life, but also in case of sickness or accident befaling him no matter how, of being cared for more logically, the doctor treating him having at hand the invaluable guide of a complete examination made previously. And how many cases of diabetes, of arteriosclerosis, of tuberculosis and of cancer would be discovered in time! The large public or private organizations and the insurance companies would do well to make general the periodic preventive examination.

By the quantity and the variety of the documents that it would gather from all parts and the studies to which it would be able to devote itself, this Institution would constitute a true and extensive practical laboratory of life, being especially useful in determining precisely the medical constitution of a district, its deficiencies and the remedies that should be applied to it. Unfortunately, we must reckon with the general indifference and custom, but we ought not to forget that the sphere of social hygiene is most extensive, unlimited one might say.

I hope and believe, however, that if a group of persons co-operated with the Association with the same zeal that Professor Hartman and Professor Delbet co-operate in the work for the prevention of cancer, the Institute of Preventive Medicine would be able, by the side of other organizations, to make some contribution to public health and to the optimum of efficiency. Social hygiene will have to undergo a great evolution, a thorough revolution of its operations.

THE REPORTING OF TYPHOID FEVER.

CITY OF BOSTON, HEALTH DEPARTMENT.

August 22, 1922.

Mr. Editor:

May I have the privilege of your columns to call attention to a matter which is of serious importance to the public, especially at this season of the year, and which should receive the consideration of the medical profession?

During the past few years it has become a more common occurrence than formerly for the Boston Health Department to discover nests of typhoid fever in the city in one of the following ways:

A death certificate signed by a physician who gives the cause of death as typhoid fever is presented to the Health Department and a burial permit requested. It is at once noted that the case of typhoid fever had never been reported to the Health Department as required by law. In such an instance, the physi-

cian will usually be found to be on the staff of one or another of the Boston hospitals and investigation will show that the deceased has been a patient in the hospital perhaps from one to four weeks and that his temperature chart for the first 48 hours after his admission was alone sufficient to justify a suspicion of typhoid fever. Investigation at the residence of the deceased will disclose other unreported cases of typhoid fever, sick or convalescent, in the family, a physician in attendance, often previous attendance by other physicians, and a history of a household spread of typhoid fever which clearly points to successive contact infections of one member of the family after another.

Or it may be that it is not a hospital but a private practitioner who may finally report typhoid fever in a family which has long been under his care.

When called on to explain failure to report cases of typhoid fever promptly to the Health Department, both hospitals and private practitioners are accustomed to plead difficulty of diagnosis with a good deal of talk about inability to get positive *Widal* reactions. How this plea may be worked is shown in the following specific instance:

On August 4 a local hospital reported the recent admission of a child ill with typhoid fever. This report led to the discovery by the Health Department that the family had been ill with typhoid in their home since May. This first case developed the first of May in a boy who had apparently picked up the disease somewhere away from home. About two weeks later the father, who was employed in the milk business, came down with the disease. The mother, another boy and then, finally, the little girl who was sent to the hospital, were successively stricken. The family were attended in their home from the beginning by a physician who enjoys a good professional reputation and who has a large practice. He states that clinically the cases were all typical typhoid fever from the first, but that repeated specimens sent into the Boston Health Department Laboratory were reported negative as to a *Widal* reaction. A prominent local physician was called in as a consultant and as a result of his advice that the attending physician was not justified in calling the cases typhoid fever in the absence of a positive *Widal* reaction, the Health Department was not notified of the cases, in spite of the evidence of the communicability of the disease. It may be stated that the records of the Health Department Laboratory show that at an interval after the onset of the disease sufficient to lead one to expect a positive *Widal* reaction, specimens were submitted to the Laboratory in the cases of three members of the family and that the Laboratory returned negative reports.

For various reasons above mentioned the Health Department is discovering when it is too late that with a physician in attendance from the start, one member of a family after another has become infected with a disease clinically indistinguishable from typhoid fever. This has happened not merely once but repeatedly. For the reasons mentioned, in a city which boasts of its opportunities for a medical education, the Health Department does not know how many unreported cases of typhoid fever there may be in the city at the present time and to what extent the health of the people may thereby be jeopardized.

A municipal health department finds it a part of its regular work to quietly clean up messes resulting from diagnostic errors in hospital and private practice and it would appear from the daily experiences of this office that there are two important principles which present-day medical education is failing to teach. One is that the spread of a communicable disease is not going to be checked if one waits until a positive diagnosis can be made before taking effective means to prevent its spread. It makes no

difference whether clinical symptoms or laboratory reports are relied on to establish a diagnosis. It also makes no difference whether the disease be typhoid fever, smallpox, diphtheria, scarlet fever, measles or whooping-cough, or any other communicable disease.

The other fundamental which our daily experience leads us to believe to be not sufficiently appreciated is that when a laboratory report is inconsistent with the clinical evidence in any case, the clinical evidence should not be discarded, but the laboratory report questioned. If a physician will make a regular practice of sending specimens taken at the same time and in the same manner to four different laboratories, he will find that he will receive a certain proportion of inconsistent laboratory reports, whether the specimens be blood for the *Widal* or the Wassermann reaction, smears for evidence of gonorrhoeal infection, or swab cultures for *Klebs-Loeffler* bacilli, or specimens submitted for any purpose whatever. It may be that inconsistent or erroneous reports are the fault of somebody in the laboratory, or of the physician who sends in the specimen, or perhaps a consequence of the falsity of some fundamental hypothesis on which the laboratory procedure, or even present-day bacteriology itself, has been built up, but the practical fact always to be reckoned with is that laboratories do return negative reports when positives are to be expected and also return positive reports when, on theoretical grounds, negatives are to be expected. To those who have acquired the habit of looking to the laboratory as a means of diagnosis, instead of as an aid to diagnosis, the procedure above referred to is recommended—the practice of always sending portions of the same specimen to four different laboratories. The results of such procedure will at least tend to jolt a habit of blind reliance on laboratory reports.

Very truly yours,

F. X. MAHONEY,

Health Commissioner.

M. VICTOR SAFFORD, Deputy, Medical Division.

SMALLPOX TREATMENT AND FACTS RELATING TO VACCINATION.

Mr. Editor:

In your issue of August 10, I note with interest Dr. Pasquale Romeo's paper on the treatment of smallpox by the violet ray.

Since coming to Ohio five years ago, I have had the opportunity of studying approximately 2,000 cases of smallpox, many of them confluent on the face and involving the conjunctiva and the mucous membranes. At our isolation hospital, practically the only treatment used was to keep the bowels flushed out and to apply vaseline to the lesions. These cases, of course, were almost invariably diagnosed as influenza and correctly diagnosed only on the appearance of the rash, hence they were always in the pustular stage when admitted. I can recall no case which showed any scarring beyond a few very slight ones on the face. It may be that the violet ray is capable of preventing pustulation; Dr. Oscar Hayes, formerly Health Commissioner of Denver, tells me that they always put their patients out in the sunlight.

Referring also to your issue of Aug. 17, p. 270, I should like to add that out of the hundreds of cases examined by me as Epidemiologist here, only 2 presented the scar of a successful vaccination. About 5 more had scars typical of a secondary mixed infection on the site of the vaccination. The others had never been successfully vaccinated.

Respectfully,

Malcolm Dean Miller, M.D. (formerly a Fellow),
Akron, Ohio, August 23, 1922.

THE STING OF THE SEA-NETTLE.

Mr. Editor:

It occurred to me that possibly this portion of a letter, that has just been written to me by a well known editor, might be of some slight interest to you. As you can see he states: "Is it not queer that we cannot find anything about the sting of the sea-nettle in the books? We know that people have been stung by those animals long before the present summer but why have not the authors had something to say about those things in their writings? I think I have read reports of such cases in some current journals but treatment, if any has been given, has never got out of those journals and into any more or less permanent books of reference. If the *Boston Medical and Surgical Journal* does publish your article be sure that I get a copy of the issue in which it appears, for I wish to speak of it editorially and to call attention to the fact that after going through the indices of almost 1000 books, I have not been able to find even a mention of the sea-nettle, much less to find any comment on its stinging powers or on the treatment of the conditions brought about by its sting. The only discoverable reference is in the *Century Dictionary*, which states that the sting of the sea-nettle causes urticaria and asks why no authorities on dermatology have ever made mention of such a skin condition, its character or its treatment. I can say that the works on therapeutics wholly overlook this particular thing in the portion of such books that is devoted to specific therapy. I may add that even the great and only Janning (*Jour. A.M.A.*) has wholly overlooked this apparently rather common matter of sea-nettle stings. Perhaps its abstractors have been asleep at the switch."

DOUGLAS H. STEWART, M.D.

128 West 86th Street, New York.

CERTIFICATE OF REGISTRATION LOST.

Mr. Editor:

Dr. Herman Augustus Tyler has, this day, reported that his Massachusetts certificate of registration as a practitioner of medicine, license number 11,846, was left by him on a table in the Hotel Bancroft, Worcester, Mass., and he has been unable to find the same although he wrote to the hotel at once, relative to the loss.

Very truly yours,

SAMUEL H. CALDERWOOD, M.D., *Secretary.*

THE RADIO TALK ON VACCINATION.

Mr. Editor:

Some of my good friends are members of the medical profession, and are doubtless readers of your excellent *JOURNAL*. It would distress me to have them suppose that I had spoken disrespectfully of physicians or in any way deserving to be characterized as with "coarse humor," in my radio talk on vaccination discussed by your editorial in the August 17 issue. I would, therefore, appreciate the courtesy of a little of your space to explain.

When I said that "the great majority of those who believe firmly in vaccination, including most physicians, take vaccination purely on faith, without giving the subject any real thought," I did not intend to be either humorous or offensive.

Physicians, having to employ in their work such a vast number of therapeutic and prophylactic agents, as they do, must necessarily take not a few of them "purely on faith." I believe no physician who may be given the opportunity to read this, will deny that such is the fact.

It is too bad that skepticism as to the merits of vaccination should so generally be resented by the medical press, as opposition to the medical profession. The practice of vaccination does not figure conspicuously in the work of the average physician and with so many pressing problems to engage his thought, he has no personal incentive to delve into the history and fundamental facts relating to vaccination, which he was taught in college to believe was an unquestionable boon to the race.

I am sure that most physicians who are candid with themselves will admit that they have always considered vaccination as something requiring no thought by reason of its long acceptance by the profession.

Quite recently, I had some friendly correspondence with an eminent physician, erstwhile president of the medical association of his State, concerning vaccination. This gentleman made certain statements which indicated that he had not kept abreast of the recent developments in the product used as vaccine virus, and when I asked further questions he frankly admitted that he could not inform me; that his work was exclusively confined to surgery and that he had not vaccinated anyone for many years. Nevertheless he was thoroughly dogmatic in his support of the practice of vaccination.

I believe that it is a serious mistake for the medical profession to elect to stand back of vaccination as now practiced, as a worthy, if not preëminent example of the advancement of medical learning.

As to the article by Dr. Heiser in the *Journal of the A. M. A.*, to which you refer, I believe any unprejudiced student, be he physician or layman, who studies the official Reports of the Philippine Health Service for the years 1918, 1919 and 1920, will be forced to conclude that the doctor must have written his article hastily, for it discredits itself by crude inaccuracies and by illicit arguments, which I will be glad to point out if you care to give me the space in which to do it.

Sincerely yours,

HENRY D. NUNN,

Manager and General Counsel, Medical Liberty League, Inc.

REPRINTS.

A few reprints of *The Treatment of Diabetes Mellitus*, by Elliott P. Joslin (*Bos. Med. and Surg. Jour.*, June 22, 1922), are available and may be procured by applying at this office. Price 50c.

BOSTON MED. AND SURG. JOURNAL,

Imperial Ottoman Medical College.....	1
Total	164

THE COLLEGE OF GRADUATION OF REJECTED APPLICANTS IS AS FOLLOWS:

Middlesex College of Medicine & Surgery.....	9
St. Louis College Physicians & Surgeons.....	8
College of Physicians and Surgeons, Boston.....	4
Massachusetts College of Osteopathy.....	2
Tufts College Medical School.....	1
University of Southern California.....	1
Total	25

(University of Budapest, on table.)

SPECIAL NOTICE

The Boston Medical Library, permanent headquarters of The Massachusetts Medical Society, 8 The Fenway, Boston, desires contributions of books, periodicals, pamphlets, medical photographs and autographs, and whatever relates to medicine. Do not throw away or sell for junk anything of a medical or scientific nature, no matter how worthless it may seem, without first giving the Library the privilege of examination.

COMMITTEE IN CHARGE OF PLANS FOR A NEW ENGLAND MEDICAL MEETING.

President, JOHN W. BARTON has appointed Dr. A. P. Merrill of Pittsfield and Dr. W. P. Bowers of Clinton to act with him in planning for joint medical meetings of the New England state medical societies.

INFANT FEEDING.

By an Anonymous Member of the
American Pediatric Society

Lines suggested by the papers on infant feeding

Soranus, he of ancient Rome,
He had a simple trick
To see if milk was fit for sale,
He merely dropped it on his nail
To see if it would stick;
Yet spite of this the babies grew
As any school boy'll tell to you.

Good Metlinger in ages dark
Just called milk good or bad
No acid milk could vex his soul
He gave it good, he gave it whole
A method very sad;
Yet babies grew to man's estate
A fact quite curious to relate.

Time sped and science came along
To help the human race,
Percentages were brought to fame
By dear old Rotch, of honored name,
We miss his kindly face;
Percentages were fed to all
Yet babies grew both broad and tall.

The calorie now helped us know
The food that is required
Before the baby now could feed
We figured out his daily need
A factor much desired;
Again we see with great surprise
The babies grow in weight and size.

The vitamin helps clarify
Why infants fail to gain,
We feed the baby leafy food
Which for the guinea-pig is good
A reason very plain;
And still we watch the human race
Go madly at its usual pace.

We have the baby weighed today
The nursing time is set,
At last we find we are so wise
We can begin to standardize
No baby now need fret;
In spite of this the baby grows
But why it does God only knows.

Away with all such childish stuff
Bring chemists to the fore,
The ion now is all the rage
We listen to the modern sage
With all his latest lore;
And if the baby fret or cry
We'll see just how the ions lie.

A hundred years will soon go by
Our places will be filled
By others who will theorize
And talk as long and look as wise
Until they too are stilled;
And I predict no one will know
What makes the baby gain and grow.

BLOOD CHANGES IN MYELOGENOUS LEUKAEMIA FOLLOWING RADIUM TREATMENT.

By B. R. WHITCHER, M.D., NEW YORK CITY.

[From the Department of Laboratories, New York Post-Graduate School and Hospital.]

History: Hare in his "Practice of Medicine" states that in 1801 Bichat in France noted a disease and condition of the blood which was probably identical with leukaemia as we know it today, and that during the early nineteenth century clinicians observed this condition in certain cases where the blood in the gross had a purulent character, and they designated it as a "suppurative haematitis," of obscure nature and origin. Our first definite conception, however, of leukaemia as we now know it, dates from 1845, when, on March 19, John Hughes Bennett performed an autopsy on the body of a man from the service of Dr. Christison in the Edinburgh Royal Infirmary who had had hypertrophy of the liver and spleen and whose blood was crowded with corpuscles which resembled those of pus.¹ For twenty months he had complained of listlessness on exertion and of a gradually increasing tumor on the left side of the abdomen. Later, other small tumors had appeared in the neck, axillae and groins. At the autopsy no suppurative foci could be discovered

in the body. Under the microscope Bennett was able to see in the blood a great increase in white corpuscles comparable to those of pus, and he found them to have a granular appearance, and on treating them with acetic acid the nuclei were clearly brought out, the nucleus sometimes consisting of one large granule about 1/200 of a mill in diameter, and at other times of two or three smaller granules "as seen in laudable pus." These colorless corpuscles were found in the blood throughout the vascular system. On stripping off a portion of the pia mater and examining the capillary vessels, all that were not too minute to contain them were found crowded with the same kind of corpuscles. He subsequently called the condition "leucocythaemia" and expressed the view that the increased number of leucocytes was independent of any inflammatory process and that the enlarged spleen "secreted" the purulent matter which caused the pyoid condition of the blood. Seven years later he published descriptions of a number of cases in which the same sort of symptoms and conditions in the blood were found.² In addition, some of these patients had epistaxis and bleeding from the gums, and one of them, a woman of thirty-three, who had enlargement of the liver and spleen, and whose blood showed large numbers of granular leucocytes, two or three times larger than the red corpuscles, showed a haemorrhagic tendency by flooding after confinement.

In January, 1848, in Schmidt's "Jahrbucher" Virchow reported the case of a body which he had dissected in August, 1845, in which the blood presented the same increase of colorless corpuscles, also associated with splenic enlargement. He called this condition "weisses Blut," or leukaemia, and in a successive series

FIG. III.

of articles in his "Archiv" he distinguished the condition clearly from pyaemia and recognized the lymphoid character of the cells in one type and their granular character in the other, and he classified the former as the lymphatic and the latter as the lienal or splenic type. Neumann first pointed out the importance of the bone marrow in the production of these large granular cells.

Pathology: In this disease, according to Dr. Richard C. Cabot³, along with the appearance and increase of the myelocytes in the blood, myeloid transformation of the spleen goes on unchecked in most cases, obedient to that mysterious stimulus which calls the blood-making system into unnatural activity; and since the spleen is not hindered by definite limitations, as the bone marrow is, it may steadily increase in size up to the time of death. However, in some cases, sclerosis of the spleen may occur,

FIG. V.

and the organ may then become lighter in weight, sometimes being only one-third of its former weight. The cellular elements are reduced from one-third to one-fifth of their normal bulk and the number of connective tissue bands about the capillaries and sinuses becomes greatly increased. This sclerosis limits the amount of myeloid change and thus prolongs the patient's life by checking the disease.

The main diagnostic feature, however, is found in the blood, where the leucocytes vary

from 60,000 to as many as 1,500,000 to the cubic millimetre. On examination there is found a very great increase of the large granular leucocytes, and more careful study shows that while at first the polymorphonuclear neutrophils are still the predominant cells, the most striking increase, as seen a little later, is in the neutrophilic myelocytes, which may constitute half or more of the total. Eosinophilic myelocytes appear in large numbers and eosinophilic leucocytes are absolutely increased, like the neutrophilic leucocytes, but they do not attain to any great proportion among the white cells. The mast cell or basophiles show a marked increase, often showing a larger percentage than that of the eosinophiles, and basophilic myelocytes are abundant. Although the lymphocytes are proportionally greatly diminished, their actual number is greater than that found in normal blood. As a rule the red cells are diminished in numbers especially as the leucocytes increase, but the early oligocythaemia is generally of a mild degree. The red cells are usually pale, resembling those in chlorosis, and microcytes and macrocytes are rare. As the disease progresses, however, nucleated red cells, chiefly of the normoblastic type, are seen, and non-granular myeloblasts are also found.

TABLE I.

VARIATIONS IN LEUCOCYTE COUNT FROM APRIL 27 TO JUNE 7, 1920.

Treatment: Until about ten years ago the disease was considered hopeless, but today a patient afflicted with this disease may be greatly benefited and marked improvement in his general condition brought about, not only by the judicious and persistent use of x-ray treatment, but by careful and persistent use of radium. By careful examinations of the patient's blood, improvement under such treatment may be observed. Benzol has also been administered in some cases with beneficial results, but in general the results have not been as good as those following x-ray or radium treatment.

Dom Etienne Gilbert² in the Paris theses of 1914 describes a number of cases of myelogenous leukaemia treated by radium in which excellent results were observed, the red cells increasing to their normal level and the leucocytes decreasing to nearly their normal level, with improvement of the patient's general health. But ordinarily the cure, according to Gilbert, is not stable, the signs of leukaemia often reappearing after some weeks have passed, and with radium treatment after this relapse, the number of leucocytes diminishes less rapidly and the curative action of radium is less effective.

Dr. Francis W. Peabody in 1917³ reported the general results of the treatment of myelogenous leukaemia by radium in thirty-six cases of the disease at the Huntington Hospital during the previous five years. One of the most striking results of radium therapy was the general clinical improvement. Extremely weak, pale and dyspneic patients who had been bed-ridden so gained in strength that they were able to be up

SHOWING DEVELOPMENT OF LEUKOPŒMIA BETWEEN OCTOBER 1 AND THE TIME OF THE PATIENT'S DEATH ON NOVEMBER 1.

and about their daily tasks; the appetite improved, the digestive disturbances became less and there was usually a gain in weight. Another marked improvement was seen in the rapid decrease in size of the spleen.

The most definite effect, however, was seen in the blood picture, the leucocytes being reduced to nearly their normal level. But at the time of his report nineteen of the patients had died and only seventeen were living.

G. Lovell Gulland² describes the treatment of myelogenous leukaemia with radium, and while he cannot say that the benefit has been permanent, he regards it as more certain and more rapid than that of x-ray. The first obvious effect is a reduction of the leucocyte count, the neutrophils, both the polymorphonuclears and myelocytic forms, being most affected in this decrease. Next are the eosinophiles and basophiles, while the lymphocytes and mononuclears

are less affected. The nucleated red cells practically disappear and in successful cases the blood may return to a nearly normal appearance. The spleen grows smaller, although it never goes back to its normal size. On account of its increased fibrosis one would hardly expect it to do so.

Dr. James Metcalf³ regards radium as of excellent value in leukaemias, especially the myelogenous form, and mentions the case of a man of fifty-nine, afflicted with the latter, who showed marked improvement under radium treatment. The radium was applied over the spleen, sternum and epiphyses of the femora and humeri. He believes the doses must be massive and frequent, as small doses only stimulate the abnormal activity.

Report of a Case: During the past two years, several cases of myelogenous leukaemia have been treated with radium at the New York Post-Graduate Medical School and Hospital and it is purposed to report briefly here observation upon one of these in which the treatment has been terminated by the death of the patient.

William E—, aged fourteen years, first came to the Post-Graduate Hospital April 27, 1920. His family and previous history were negative. In July, 1919, his mother observed that he did not play with his former vigor and energy and he was pale and complained of weakness and loss of appetite. He was examined and given medicine by a physician and continued to decline in health. In October, 1919, he was sent to the Staten Island Hospital on account of enlarged spleen, and remained there for a month, when he was discharged with a very bad prognosis.

Physical examination, upon admission, April 27, 1920, showed a very thin and generally anaemic boy. The lungs and heart were negative except for a soft systolic murmur at the second interspace. Abdomen was protuberant and distended by a large mass on the left side extending obliquely downward from the left hypochondrium, to within 25 cm. of the pubic symphysis. Liver was palpable 8 cm. below the costal margin. No free fluid was detected. Superficial veins were prominent, especially over the abdomen and lower extremities. The Wassermann test, taken on April 27, was negative. A provisional diagnosis of splenomyelogenous leukaemia was made.

On April 28, 1920, the first blood count was taken. It showed 3,150,000 red cells per cubic mm., 161,800 leucocytes and 50% of haemoglobin by Tallquist. A differential count of 500 white cells showed 35% of polymorphonuclear neutrophils, 3.6% of lymphocytes, mononuclears and transitionals, 7.2% of eosinophiles, 7.6% of basophiles, 37% of neutrophilic myelocytes, 7.4% of eosinophilic myelocytes, 3.2% of basophilic myelocytes, and 4% of myeloblasts. A few normoblasts and macroblasts were seen among the red cells. Some

more smears were taken two days later, which showed a similar blood picture with an occasional myelocyte undergoing mitosis.

On April 29, at 4 p. m., 100 milligrams of radium were applied over the enlarged spleen, the site of application being changed to a new skin area every hour until fourteen hours had elapsed. The radium was contained in a glass tube encased in a gold tube 0.1 mm. in thickness, the whole being contained in a brass tube 1.5 mm. in thickness and a screenage of 3 mm. of lead and 3 mm. of rubber and a towel folded to a thickness of 2 cm. was interposed between the brass tube and the patient's skin. The radiation therefore consisted of what is designated as the gamma rays.

On May 4th the leucocytes had decreased to 135,400 per cubic mm., but two days later they were found to have increased to 312,000 per cu. mm. Another count taken on the following day showed 212,000 leucocytes.

The second radium treatment was given on May 10, when 100 mg. were applied, beginning at 3:50 p. m., in twelve successive applications over different areas, each of duration of one hour, with screenage of 1 mm. of lead, 1 mm. of rubber and a folded towel of 2 cm. thickness between the brass tube and the skin.

By May 13th, the leucocyte count fell to 199,000; two days later to 162,000 and by May 20th it had fallen to 77,400 (See Table I). On May 26th, it was found that the leucocytes had increased to 188,400, and on this date, 120 mgm. of radium were applied over the spleen over eleven successive areas, with a screenage of 1 mm. of lead, 3 mm. of rubber, and a folded towel of the same thickness as before, in addition to the brass tube. The leucocyte count began gradually to diminish, going down to 112,000 by June 1, and 111,000 by June 3. On that date 120 mgm. of radium were applied in seven successive applications to different skin areas over the spleen with a screenage of 3 mm. of rubber and 2 cm. of folded towel, for periods of two hours each. On June 7 the leucocytes had diminished to 52,000, while the red cells had increased to 3,926,000 per cu. mm. The differential count showed the different leucocytes to be in more nearly normal proportions, the polymorphonuclear neutrophils being 37,000 per cu. mm. and the lymphocytes and mononuclears 7,800, while the myelocytes were now only 3,000 per cu. mm. On June 8, the patient was discharged from the hospital.

On July 2 he returned for examination and treatment. The spleen was now greatly reduced in size, the splenic notch being 9 cm. from the tip of the xiphi-sternum, the lower border 14 cm. from the costal cartilage and the right border 11 cm. from the median line. The leucocytes had fallen to 12,000 per cu. mm. On July 6, at 10 a. m., 120 mgm. of radium were applied over four successive areas over the spleen for two hours on each area, with a screenage of 3 mm.

of rubber and a folded towel as before. He returned on September 9, and this time the leucocytes were found to have increased to 28,400. He was now given treatment with 60 mgm. of radium in eight successive applications for sixteen hours altogether, with a screenage of rubber and folded towel.* On October 7, when he came again, the leucocyte count was the same but the polymorphonuclear neutrophils had risen from 14,484 to 17,792 per cu. mm., and the lymphocytes and mononuclears had risen from 1,420 to 8,400 per cu. mm., while the myelocytes were no longer found. On October 28, when he came again for treatment, he showed a decided improvement, the leucocyte count being 15,400 and the blood picture appearing much more normal. The most conspicuous feature in the differential count of this date was the excess of basophilic leucocytes. These cells were 9% of the leucocytes or 1,376 per cu. mm. The polymorphonuclear neutrophils were 9,080, the lymphocytes and mononuclears 3,450 and the myelocytes only 1,016 per cu. mm. The spleen was firm and palpable and the patient had gained ten pounds, his weight now being seventy-nine pounds. The patient was given treatment with 60 mgm. of radium, applied over six successive areas over the spleen for three hours on each area, with a screenage of 1 mm. of rubber and a folded towel, 2 cm. in thickness.

During the winter and spring the patient called at intervals, approximately once every month, for treatment, and on each visit he was treated with radium in fifty-five to sixty milligram amounts, in five to six applications of three hours each over successive areas in the splenic region, with a screenage of 1 mm. of rubber and a folded towel of the same thickness as before. As will be seen in the tables showing the leucocyte variations, the polymorphonuclear neutrophils approached to more nearly their normal level, and the myelocytes showed a marked decrease, none being found in the differential counts taken in February and March, 1921, and only a few being found in the counts of May and June. The patient's general condition was greatly improved, the anaemic pallor and prominence of the superficial veins having disappeared, and the spleen was reduced nearly to a quarter of its former size.

The patient was away in the country during the summer, but returned for treatment September 1. At this time it was found that the leucocytes had increased to 69,800 per cubic mm., with an increase of myelocytes above the lymphocytes. He was given treatment with 90 mgm. of radium over six successive areas of skin with the same amount of screenage as on last visit. He returned a week later for examination and treatment, and this time the leucocyte count had fallen to 20,000. He was now treated with 100 mgm. of radium in four successive applications of four hours each.

*The record does not give the thickness of the rubber.

On September 29, the patient came to the hospital complaining of drowsiness, fever and loss of appetite, and a herpetic sore on the lower lip. The leucocytes had risen to 58,200, but the differential count showed a most striking contrast to the previous ones, in that the polymorphonuclear neutrophils had fallen to 4% or only 2,328, while the lymphocytes had risen to 58% or 35,596 per cu. mm. The patient bled occasionally from the nose and rectum. The red corpuscles were 2,328,000 per cu. mm. On October 7, the total leucocyte count showed a remarkable fall to 1,800 per cu. mm. and the anaemia was more marked. The sore on the lower lip had formed an ulcer the size of a silver dollar and this was diagnosed as gangrenous septic dermatitis following deep infection of the herpetic sore. By October 18, the leucocytes had fallen to 310 per cu. mm., the red cells to 1,148,000 and the haemoglobin to 23.5%. On October 25, the patient was transfused with 500 cc. of blood with only slight improvement. On November 1, the red cells were 1,252,000, the haemoglobin 24% and the leucocytes 380 per cu. mm., of which there were 18% polymuclear neutrophils, 70% lymphocytes and 12% basophiles. The patient died that night at 11:00 o'clock.

The autopsy performed the next day at 9 a. m. showed the following conditions:

General Appearance: At the left lower angle of the mouth was a serpiginous ulcer, about 40 mm. in diameter. Its floor was sunken and covered with a brown crust. The skin over the left hypochondrium showed several dull white scars, with pigmented borders, level with the skin surface, evidently due to radium burns, the largest being 50 x 17 mm. in extent.

Abdomen: 2,000 cc. of opalescent yellow fluid containing fibrin flakes found in the abdominal cavity.

Enlarged spleen weighing 780 grams, adherent to parietal peritoneum beneath cutaneous scars, and containing deep fibrous scar tissue sending fibrous trabeculae into the splenic substance.

Liver weighed 1,930 grams. Its capsule was thickened and lobules enlarged.

Posterior mesenteric vein and tributaries congested. Mesenteric and retroperitoneal lymph nodes brown and moderately enlarged.

Gelatinous oedema of retroperitoneal tissue behind ascending colon with gas bubbles and putrefactive odor, evidently due to agonal invasion of anaerobic bacteria.

Thorax: 200 cc. of clear yellow fluid in each pleural cavity. Oedema in posterior portions of both lungs, with firm airless reddish-brown nodule in upper lobe of right lung.

Small petechial haemorrhages in pericardium, both parietal and visceral.

Yellow marrow of long bones replaced by dark red marrow.

Microscopic Findings: Spleen: Capsule

showed dense fibrous thickening with thick fibrous scar tissue extending into the splenic substance by irregular fibrous trabeculae, infiltrated along the borders with haemosiderin granules. The Malpighian corpuscles were largely replaced by fibrous connective tissue and the splenic pulp was infiltrated with a fibrous network containing many sinuses and capillaries. Only a few small patches of round cells resembling splenic pulp and occasional accumulations of red cells and many round cells were found. Few polymuclear and eosinophile cells and very few myelocytes were found. The red cells of the vessels were very scanty, pale, and irregular in form.

Bone Marrow: Smears from the marrow of the third lumbar vertebra showed, out of a count of 200 white cells, 12 polymuclear neutrophils, 112 lymphocytes and mononuclears, 1 eosinophile, 4 basophiles, 26 neutrophilic myelocytes and 33 disintegrated. Occasional nucleated red cells were seen. Sections of the marrow showed ragged masses of red corpuscles, including many normoblasts with occasional microblasts and a few megaloblasts and rarely a giantoblast. Neutrophilic and eosinophilic myelocytes and occasional polymuclears were seen, with large numbers of nongranular mononuclear cells greatly outnumbering the myelocytes and the polymuclears.

Smears from the shaft of the femur showed, out of a count of 200 white cells, 8 polymuclear neutrophils, 114 lymphocytes, 6 eosinophiles, 3 basophiles, 12 neutrophilic myelocytes, 3 eosinophilic myelocytes, 1 basophilic myelocyte and 33 disintegrated cells. During the count, 19 normoblasts, 7 microblasts, 4 macroblasts and 1 megaloblast were found. In the sections the marrow substance showed a more compact mass of cells than in the third lumbar vertebra. The myelocytes and polymuclears were more abundant and large numbers of non-granular mononuclear cells were seen. Sections from a rib and from the sternum showed a similar appearance to that of the third lumbar vertebra, except that the myelocytes and the polymuclears were less numerous.

Liver: Some of the cells contained minute fat particles. In a few places haemosiderin granules were found in the intercellular channels. In one area these channels were distended into spaces resembling alveoli, from 1-40 to 1-10 mm. in size, evidently having formerly been distended with accumulations of myelocytes.

In the mesenteric lymph nodes the lymphoid tissue was mingled with red cells largely disintegrated. In some glands there was an increase of fibrous connective tissue in and around the lymphoid tissue, with some thickening of the vessel walls.

Lungs: In a section including the nodular portion, the alveoli were solidly filled with blood, but some contained plasma with few red cells, many of these being disintegrated. The

alveolar capillaries were much engorged. Very few leucocytes were found except endothelial cells, of which there were many.

In conclusion it will be seen that, while the patient appeared to be greatly benefited for the time by the radium treatment, its effects were temporary and when the patient discontinued treatment for two months he suffered a relapse. His subsequent condition showed the need of using the utmost caution in giving radium treatment, especially after a relapse. While an apparent improvement in the blood picture did follow the first treatment with radium after the patient's return, the most striking phenomenon after the second treatment was the rapid fall in polymuclear leucocytes, the blood picture coming to resemble that of lymphatic leukemia, and the rapid leucopenia and anaemia which followed, resulting in the patient's death.

The observations in this case show, on the one hand, that the application of radium in myelogenous leukaemia does produce an apparently beneficial effect on the patient, if the amount of radium applied is regulated with caution, as the leucocyte count is reduced to nearly its normal level, the myelocytes are greatly decreased, and at times made to disappear altogether, the blood is brought to a more nearly normal appearance, and an apparent general improvement takes place in the patient's clinical condition. But the treatment needs to be given at regular intervals. On the other hand, the study of this case indicates that radium is a factor fraught with danger, and that caution is necessary in regulating the amount to be applied, lest an excessive amount of radium or too frequent application may cause undue destruction of the leucocytes and so injure the reproductive powers of the bone marrow that a rapid leucopenia and anaemia result.

While Dr. Metcalf⁹ in his treatment of myelogenous leukaemia with radium has applied it over the sternum and epiphyses of the femora, and humeri, as well as over the enlarged spleen, it has been deemed of late, here at the Post-Graduate Hospital, to be a better procedure to apply the radium over the enlarged spleen only, and the lymph nodes, if enlarged, but to let the bone marrow alone, until the myelocytes have entirely disappeared from the blood. There appears to be danger that, in treating the bone marrow at the same time, its power to produce new red cells may be weakened so that the red cells and haemoglobin decrease along with the leucocytes. However, much more experience will be required to ascertain exactly the effect to be expected and the best mode of applying radium therapy in this disease.

The writer gratefully acknowledges his indebtedness to Dr. George T. S. Willis, Associate in Medicine, in charge of radium therapy, who had the care and treatment of the above case, for permission to utilize it in this report.

BIO-CHEMICAL STUDIES IN TEN CASES OF DEMENTIA PRÆCOX.

BY

KARL M. BOWMAN, M.D., BOSTON, MASS.
JOSEPH P. EIDSON, M.D., WHITE PLAINS, N. Y.
STANLEY P. BURLADGE, M.S., ITHACA, N. Y.

THE following bio-chemical studies of dementia præcox were made in the hope that they might aid in our understanding of the disease and that we might discover some positive data which would be of value in working out the etiology of the disease or which would serve as a means of differential diagnosis.

The following studies were made:

1. A twenty-four hour specimen of urine was examined quantitatively for total acidity, total nitrogen, ammonia nitrogen, uric acid and chlorides. The methods used were modifications of Folin's methods. The chlorides were tested by adapting Whitehorn's methods.
2. The renal function test was made in the usual way by injection of one cubic centimeter of phenolsulphophthalein solution subcutaneously and examining the urine at the end of one and two hours.
3. The blood count was made in the usual manner. The hemoglobin was estimated by a Dare hemoglobinometer. The pipettes used were certified by the Bureau of Standards.
4. A twelve-hour fasting blood was examined quantitatively for non-protein nitrogen, dextrose, uric acid, chlorides and carbon dioxide combining power of the plasma. The methods used were those of Folin and Wu, Whitehorn and Van Slyke.
5. The blood sugar tolerance curve was obtained by giving the patient, who had fasted for twelve hours, 1.75 grams of dextrose per kilo of body weight. The dextrose was dissolved in two and a half times its weight of water. The fasting blood and blood taken one, two and in some cases three hours after ingesting the dextrose were examined. The urine was examined qualitatively for sugar in the latter series.
6. The Goetsch test was made by injecting one-half cubic centimeter of adrenalin 1:1000 intradermally and following the pulse, blood pressure, etc., as described by Goetsch¹.
7. The basal metabolism was estimated by a Jones metatbolometer. At least one and usually two checks were run.

The first nine cases were studied at Bloomingdale Hospital and the tenth at the Boston Psychopathic Hospital. The laboratory studies on the tenth case were made by different technicians and the methods used were different. The non-protein nitrogen and dextrose of the blood were estimated by Benedict's method. The

basal metabolism was done with a portable Benedict apparatus.

After an interval of six months the blood sugar curves and basal metabolisms were repeated on as many cases as possible.

The findings are as follows:

*ANALYSIS OF URINE (24 hours specimen).

Case	Titrated Acidity C.C. N/10 NaOH	Total Nitrogen	NH ₄ Nitrogen	Uric Acid	Chlorides as NaCl
1	136.5	5.25 grams	0.15 gram	0.31 gram	
2	636.6	12.53 grams	0.69 gram	0.574 gram	
3	284.4	5.78 grams	0.16 gram	0.36 gram	6.52
4	222.6	1.96 grams	0.3 gram	0.33 gram	
5	438.6	11.42 grams	0.75 gram	0.50 gram	
6	500.25	12.79 grams	1.16 grams	0.395 gram	11.87
7	495.9	11.75 grams	1.41 grams	0.33 gram	12.345
8	323.4	8.51 grams	0.10 gram	0.49 gram	5.78
9	240.8	6.08 grams	0.34 gram	0.28 gram	4.12

*The possibility of incomplete specimens, due to patient's lack of coöperation, must be considered.

The urine findings show considerable variation. They add nothing, however, to Folin's² studies on the subject, and we agree with Folin's conclusions that "individual peculiarities or abnormalities of metabolism, *i. e.*, pronounced from the standard values . . . are also very

numerous, but so far it has been found impossible to identify any one metabolism peculiarity with any particular form of mental disorder."

The renal function tests show a normal functioning of the kidney.

The blood counts show an essentially normal picture. The hemoglobins are high but within normal limits. The red blood cell counts are likewise high but we feel should not be regarded as of any importance from a pathological standpoint. While the average red blood cell count is usually given as 5,000,000 for males, there is a fairly wide normal variation. For instance, Ehrlich and Lazarus³ give the normal variations as from 4,000,000 to 7,000,000, and McJunkin⁴ says: "In normal blood there are 4,000,000 to 6,500,000 red blood corpuscles per cubic milli-

RENAL FUNCTION TEST

meter. The white blood cell counts are normal. The differential counts show a normal relation of the different types of cells, except that two cases show an eosinophilia of 5 per cent."

The blood chemistry findings are essentially normal, with a tendency towards a slight rise in the blood sugar. The literature on the subject has been fully reviewed by one of us⁵, and we feel that there is no reason to consider that the fasting blood shows any characteristic abnormality.

BLOOD SUGAR CURVES.

Before considering our findings it might be well to briefly summarize the literature on the subject.

Olmstead and Gay⁶ have recently made rather extensive studies on the subject. They suggest the use of the term "blood sugar curve after glucose meal" or "blood glucose curve." They have made an interesting classification of types or curves, which is given below. The method used was essentially the same as that described at the beginning of this article.

The normal curve has a fasting level of 80 to 120 mgm. At the end of the first hour there is a hyperglycemia of from 140 to 190 mgm. and at the end of the second hour the blood sugar has returned to the normal limits. The third hour is still within normal limits but is very frequently lower than the second hour.

BLOOD SUGAR CURVES.

Case	Milligrams Dextrose Per 100 C.C. Blood			
	Fasting	1st hour	2nd hour	3rd hour
*1	87	154	91	81
2	157	250	179	..
*2	111	200	115	60
3	119	232	165	..
4	137	175	183	..
5	120	277	146	..
*5	100	143	100	75
7	114	232	236	..
*7	105	266	191	143
8	128	180	132	..
*9	83	200	187	171

* These tests were made after an interval of six months. In cases 1 and 9, cooperation could not be secured for the first series; in cases 6 and 10, cooperation could not be secured for either series.

Abnormal curves are divided into two main classes. The term "sustained" curve applies to all curves which show an abnormally sustained hyperglycemia. These "sustained" curves are divided into two groups. In group two are included cases in which there is still hyperglycemia at the end of the second hour, but which show a normal sugar content at the end of the third hour. Group three includes cases in which the hyperglycemia is sustained even at the end of the third hour.

The term "subnormal" curve applies to those cases which show a normal fasting sugar and no hyperglycemia following the administration of the glucose meal. According to the authors, this may be caused by one or both of two possi-

bilities: "Either a delayed absorption rate or an increased glycoemic function." They feel that the "subnormal" curve of hypothyroidism is not due to delayed absorption, whereas delayed absorption may occur in the subnormal curve of hypopituitarism.

Among a large series twelve cases of dementia praecox were examined. Five showed normal curves. Three showed No. 2 hyperglycemic curve. Three showed No. 3 hyperglycemic curve and one showed a subnormal curve.

They conclude: "The pathologic conditions in which the form of blood glucose curve is usually (within certain limits) constant, are: (1) hyperthyroidism and hypothyroidism; (2) hypopituitarism; (3) diabetes mellitus."

Kooy⁷ examined a large number of cases of mental disease, including ten cases of dementia praecox. These latter were all cases of several years' duration (except one which had been sick for six months only) and were considered typical cases. The procedure used was as follows: The fasting blood was taken in the morning; then a breakfast of 100 gms. of bread and 200 c.c. of milk was given. Blood was drawn at forty-five minute intervals for three times. Patients avoided exercise, excitement, etc. The average blood sugar findings of the ten cases were: Fasting 93 mgm.; three-quarters of an hour, 123 mgm.; one and one-half hours, 110 mgm.; two and one-quarter hours, 110 mgm. Thus Kooy found a consistent No. 2 hyperglycemic curve. (Blood was not taken after two and one-quarter hours.)

Raphael and Parsons⁸ examined the blood sugar curves of several types of mental disease, including eleven cases of dementia praecox, using the standard technique.

They conclude: "The curves of the dementia praecox group are strikingly different from those of the others. (Manic depressive depression, hypomanic and norms.) They show a great variation in their acme levels, yet the shape of all curves within the group is practically the same. Curves 1 to 7 inclusive are all practically parallel to one another. All of these cases were in the acute phase. The general shape of the curve differs from the normal in that the initial fasting level is lower, the acme is relatively high and the return to the primary level takes more than three hours, there being a very definitely delayed tolerance.

"Whether or not all of the variations of these curves can be explained by the emotional reactions of the patients, this in turn being in interrelation with a hypersecretion of epinephrin, thus mobilizing the glycogen of the liver and hence increasing the amount of glucose in the circulatory blood is an unsettled question.

"It may be stated on the basis of the data secured in these experiments, employing the Benedict modifications of the Lewis Benedict method for blood sugar, that tolerance curves differ from those obtained in normal individuals

... that in each clinical group, the curves had features in common that suggest a curve type; that among cases of dementia praecox tolerance curves vary according to the phase of the clinical course."

Lewis and Davies² studied twenty-two cases of "schizophrenia." Following the classification of Olmstead and Gay, they found subnormal curves in sixteen of their cases, a sustained curve in five cases and an "atypical" curve in one case.

We find, therefore, that different observers report quite different curves in the blood as a result of glucose feeding and that all types of curves are reported.

In our own cases we found normal curves in three cases, sustained curves in three cases and two cases which gave sustained curves at the time of the first examination and normal curves at the time of the second examination six months later.

The height of the curve is abnormal in seven of eleven tests, ranging from 200 mgm. to 292 mgm.

The interpretation of these findings can best be taken up in connection with the basal metabolism.

Goetsch¹ regards the injection of epinephrin as a specific test for hyperthyroidism. There is considerable dispute as regards the specificity

GOETSCH TEST.

of this test, but there is no question that a large percentage of cases of hyperthyroidism give a positive reaction to this test.

The consistent negative reaction of all our cases to this test can be considered as very strong evidence that hyperthyroidism was not present.

BASAL METABOLISM.

The basal metabolisms are of interest. In the first series of readings only three are normal, taking ± 10 per cent. as the normal limits. The other seven are all decreased, ranging from -12 per cent. to -31 per cent. In the second series of readings, which were done after an interval of six months, the readings in eight cases are all within normal limits. Two cases left the hospital and therefore could not be repeated. While there is some increase in many of the cases, the tendency to remain above or below the zero reading is unchanged, except in one case, No. 9. In this case there was a history of recent enlargement of the hands and head with an acromegalic picture. Cases 1 and 7 showed some improvement in the six months' interval. It is noteworthy that not a single test in the entire series gave an abnormally high reading, and, except in Case 9, the highest reading was +5 per cent. On the other hand, abnormally low readings were common, the lowest being -37 per cent.

DISCUSSION.

It is well known that certain endocrine conditions influence the blood sugar tolerance curve and the basal metabolism. There have likewise

been numerous attempts to correlate dementia praecox with various endocrine disorders, particularly hypothyroidism¹⁰ and hypogonadism¹¹. The literature is much too full to be reviewed here and is as yet in a very chaotic state.

It cannot be said that our studies have clarified the matter in any way. We find nothing to confirm a simple dysfunction of a single endocrine gland as a constant condition in dementia praecox.

While the tendency towards low basal metabolisms is suggestive of hypofunction of some gland, the tendency towards abnormally sustained sugar curves is equally suggestive of hyperfunction.

It is perhaps worthy of note that in no case was there increased basal metabolism (which is usually a sign of hyperfunction of some gland), nor was there a subnormal sugar curve (which is usually a sign of hypofunction of some gland).

The two other endocrine conditions which might explain our findings are either a pluriglandular condition or an altered secretion of a single gland. It is manifestly impossible to more than mention these possibilities.

CONCLUSIONS.

As a result of a series of biochemical studies on ten cases of dementia praecox no constant findings were obtained which would serve to explain dementia praecox on the basis of a simple dysfunction of a single gland.

There was found a tendency towards a low basal metabolism and an abnormally sustained

blood sugar curve, but such findings were not constant.

In no case was there an increased basal metabolism nor was there a subnormal (flat) blood sugar curve.

CASE 1. Dementia praecox, paranoid type. Male, 49 years. Physical examination negative.

CASE 2. Dementia praecox, paranoid type. Male, 17½ years. Physical examination showed right pupil slightly larger than left. Blindness of right eye. Tremors of fingers and tongue. Deep reflexes exaggerated but equal. Pubic hair of feminine distribution. Body contour otherwise normal.

CASE 3. Dementia praecox, paranoid type. Male, 30 years. Physical examination showed right pupil slightly larger than the left. Tremors of fingers and tongue. Deep reflexes exaggerated but equal. Blood pressure 95/66.

CASE 4. Dementia praecox, simple type. Male, 28 years. Physical examination showed rather poor nutrition and fine tremor of fingers.

CASE 5. Dementia praecox, paranoid type. Male, 40 years. Physical examination showed thyroid palpable, tremors of tongue and fingers and deep reflexes exaggerated but equal.

CASE 6. Dementia praecox, paranoid type. Male, 27 years. Physical examination showed no neurological findings. Blood Wassermann was weakly positive. Spinal fluid was negative to all tests.

CASE 7. Dementia praecox, paranoid type. Male, 33 years. Physical examination was negative except for poor nutrition.

CASE 8. Dementia praecox, simple type. Male, 26 years. Physical examination showed fine tremor of tongue and fingers. Deep reflexes were hyperactive with tendency to patellar ankle clonus on the right.

CASE 9. Dementia praecox, paranoid type. Male, 24 years. Physical examination showed tendency towards acromegalic type of bone conformation. History of recent enlargement of hands and head. Otherwise negative.

CASE 10. Dementia praecox, simple type. Male, 15 years. Physical examination showed poor development. Fingers long and graceful. No axillary hair. Pubic hair of the feminine type.

Medical Progress.

REPORT ON DERMATOLOGY.

By JOHN T. BOWEN, M.D., BOSTON.

SUSCEPTIBILITY TO POISON IVY.

BROWN¹, of the Department of Pharmacology of the University of Minnesota, has recorded the results of his experiments as to the variability in susceptibility to poisoning. He truly says as to treatment that almost everything conceivable has been employed, and that this is evidence that we are still ignorant as to what are the best measures of relief. He began with the belief that some persons are insusceptible to the poison, but has changed his opinion in the light of his own investigations.

Observations were made on a group of students who were willing to submit to experimentation, by placing a piece of the fresh leaf on the left arm, and holding it there by means of adhesive plaster. This was removed at the end of 12 hours, and the susceptibility estimated by the time required to produce a reaction and by the different degrees of severity. It was found that in a group of nine persons, three were, as at the time supposed, insusceptible. Three of the remaining six had previously considered themselves immune, but the reaction was longer delayed than in the case of the other three. On an average it required approximately 2-1.3 days for the symptoms to appear after the leaf had been applied. To another group of 11 students a tincture prepared from the leaves was applied to the arm, and the area covered with adhesive plaster. All except two showed a reaction, and among those showing positive results were two who had not been poisoned by the leaf in the preceding experiment. The tincture appeared to give more certain results than the leaf; but the degree of reaction, as in the case of the leaf, bore no relation to the time required to produce the eruption.

Brown isolated a fixed oil or oily substance from the leaves, which is probably the same as the toxicodendrol of Pfaff. This failed to produce an eruption in only a very few instances. With regard to the spreading of the eruption, some have held that it is carried from the initial point to the other parts of the body by the hands or clothing. This has been proved to be the case in some instances. Brown's experiments by covering the part to which an extract of the leaves had been applied with a celluloid vaccination shield, show that the eruption may be spread to the body by means other than direct or indirect contact; presumably, therefore, through the blood or lymph. His experiments did not show that the serous exudate from the ruptured vesicles could spread the eruption. In the case of a person who chewed the leaves, the mucous membranes of the mouth were not af-

fected, and, moreover, of more than 100 observed cases of the eruption there was no instance of involvement of the mucous membranes. Since it has been proved that the active principle is not volatile, the cases of people who claim to have been poisoned by merely going into a vicinity where the plant happened to grow, are best explained by the supposition that insect carriers are responsible. The following conclusions are drawn:

1. There is a variability in susceptibility in different persons.
2. There is evidence pointing to the variability in the susceptibility of a given person.
3. The time required for the onset of symptoms in 19 clinical cases in which reliable data were obtained was from 5 hours to 8 days.
4. The eruption may spread over the body, without conveyance of the poison from the initial lesion through the agency of the hands or clothing.
5. The serous exudate from the vesicles plays no part in spreading the eruption to other parts of the body.
6. There is no evidence of total insusceptibility.
7. It is probable that the poison may be conveyed through the air by insects, rather than by dust or pollen.

BREAKING OF THE HAIR.

R. Sabouraud² states that while it is easy to recognize the cause in the larger number of cases of breaking of the hair, or trichoclasia, in a certain number it remains obscure. The most beautiful hair is admittedly encountered in young girls of from 12 to 16 years, and it is only after this age that the hairs begin to break. Sabouraud distinguishes three types, first simple trichoclasia, a transverse fracture of the hair, without the preceding occurrence of any node at the point of breaking. In trichorrhexis, on the contrary, there appear from one to three grayish swellings along the free ends of the hair, which are the points of fracture, and here the hair is split up into fibrils. When the breakage has taken place the ends of the broken hairs take the form of a broom, and this condition is called trichoptilosis. Oftentimes these three types or stages may be seen in the same head of hair, and occasionally in great numbers. It has been believed that this affection is preëminently an oriental one, and especially prevalent in Constantinople, the cause being a parasite. It has been further asserted that the fact that the false hairs of the same head may be equally affected is a proof of the parasitic etiology. Hence an active anti-parasitic treatment, without favorable result, the rule being that the affection once established, progresses and never disappears. This is an entirely wrong view, according to

Sabouraud, who maintains that the treatment is exactly the reverse of that indicated, since the strongly alkaline soaps used remove the oil and add to the fragility of the hair. He considers the parasitic theory a wrong one, and that the trichoclasia is of traumatic and artificial origin. Besides the shampoos, curling, "permanent waving," dyeing and bleaching contribute to the bad effects. Sabouraud speaks vigorously against the recent practice of permanent wave, having seen dozens of cases in which the hair was brittle, broken and covered with nodes after the procedure, and a number of cases in which the hair was permanently ruined. The proper treatment of these conditions is cutting the hairs beneath the point where they are affected, avoiding the causes above enumerated that have been responsible, and especially the shampooing with alkaline soaps.

In résumé Sabouraud affirms that trichorrhexis nodosa, and the simple trichoclasias represent in no sense a disease of the hair. It is owing to the procedures of the coiffeur that the hair is made susceptible to various sorts of traumatism, especially those produced by irritating lotions and soap washings, by dyeing and bleaching, curling and waving. Besides these cases, which are of daily occurrence, there are certain cases of spontaneous trichorrhexis of the mustache, of trichoclasia *en plaques* of the hair without any perceptible lesion of the skin, and also some instances of trichoclasia *en plaques* on thickened, dry, and pruritic skin, which are quite rarely met with.

PEMPHIGUS FOLIACEUS FROM ARSENOBENZOL.

Nicholas and Massia³ have observed three instances of this affection, which is an unusual occurrence among the large number of forms of cutaneous disturbance due to the administration of arsenobenzol. Moist lesions are very common, and the generalized lesions are not rare, but for the most part one sees exfoliative erythroderma with redness and desquamation.

Pemphigus foliaceus seems from these observations to appear after the last, and to be preceded by a simple erythema which gradually extends, becomes infiltrated and squamous and is followed by the appearance of vesicles and bullae which open as soon as they are formed. Hence erythema, slightly squamous, more or less pruriginous and situated especially in the folds and on the neck, appearing during the course of treatment with arsenobenzol, should give immediate cause for alarm. The evolution is rapid and in a few days the symptomatic picture is complete. The scales are always very abundant, and the exudation more or less abundant. There are no mucous membrane lesions, nor is the scalp affected. There is no marked rise in temperature, and no notable lesions of the internal organs, except a nephritis observed in one case. There is much prostration, sometimes delirium, and always anorexia.

This symptomatology is much like that seen in the ordinary case of pemphigus foliaceus, but there is much difference in the evolution of the arsenobenzol cases. In the ordinary case of pemphigus foliaceus the duration is of months and years and the affection is very often fatal; whereas in the arsenobenzol cases the evolution is much quicker, and healing of the cutaneous lesions is the rule. In the writers' second case, it is true, there was a fatal ending, but this did not occur until the skin lesions were almost wholly healed, and the case was complicated by a gangrene of the right foot with arteritis, which they are not able to assert to have been of arsenical origin, although they cannot exclude this cause. In any case pemphigus foliaceus of arsenobenzol origin is a dermatosis of less gravity than the ordinary form and its evolution is shorter, and this is true also of the other cutaneous types from this cause. As to the pathogenesis of these cases, the writers think that anaphylaxis may be at once eliminated, on account of the tardy appearance of the eruption, its irregularity and the number of arsenical injections, nor do they consider that it can be due to a latent infection. They incline to the view that there is a true arsenical intoxication. Perhaps there is a cumulative intoxication caused by a perversion of functioning by the organs which should eliminate the arsenic, particularly the liver. The treatment of the cutaneous lesions is in the main prophylactic. In the course of treatment by arsenobenzol, the attention should be especially arrested by the appearance of more or less marked erythema, or of eczematous lesions of the folds, and the treatment then promptly suspended before the process has progressed to the production of more serious lesions.

PSORIASIS AND ITS TREATMENT.

Several papers on this subject were read at the meeting of the American Dermatological Association held on June 2-4, 1921. Jamieson⁴ of Detroit related the results of his experimental work on blood nitrogen in psoriasis. The investigations of Schamberg and his associates have shown that persons suffering from psoriasis are capable of retaining nitrogen to a remarkable degree, much greater than is observed in any other condition. They are therefore inclined to believe that a high or even relatively high nitrogen diet has a baneful influence on psoriasis, and that there is little doubt that a low nitrogen diet has a favorable influence on the skin lesions. Their ingenious explanation is that the epithelial cells of the skin keep on growing as long as there is available protein in the system, and when this is exhausted their growth is checked. Hence if the patient is kept on a low protein diet this point of exhaustion is hastened, while a high protein diet stimulates the epithelial cell growth and delays improvement. Jamieson firmly believes in the metabolic origin of psoriasis. In analyzing the many different reports of psori-

asis from all parts of the world, it is seen that there are many varied conditions preceeding an attack of psoriasis, but that all are conditions that may produce a profound disturbance in the body metabolism. These disturbances may also cause remissions of the psoriasis, and therefore it seems that "psoriasis is a definite clinical dermatologic manifestation, due to faulty metabolism induced by many underlying conditions and manifesting itself in an incomplete keratinization of the dermal cells."

In Jamieson's investigations 45 cases of psoriasis were examined, some of them having only a few nitrogen determinations, others returning regularly at monthly intervals. Some of these cases were extensive and severe, others showed only a small number of lesions, but were of a rebellious type. The conclusions drawn from these investigations are that it is impossible to state that the increase or decrease of the lesions in the cases examined corresponds with an increase or decrease of either total non-coagulable nitrogen or uric acid. The uric acid curve was at its low point during the warm months of summer and early autumn, and the total non-coagulable nitrogen curve is also similar in this respect.

With regard to the treatment of psoriasis, Sutton⁵ of Kansas City relates his results with a method employed during the last two years, which he began to use as a war measure in order to get rid of the eruption as quickly as possible in candidates for the aviation corps. The method is to be used only in the quiescent stage and not during the acute or eruptive periods. Careful general physical examination should precede the treatment and nephritis or a serious heart lesion would debar it. In 42 cases he has had good results. The method consists of the injection of a foreign protein (in the form of an autogenous colon vaccine) and the liberal use of a chrysarobin ointment, much stronger than that commonly applied (20 per cent.). Sutton states that he has been gradually discarding, for several years, the more complicated formulas in the local treatment of psoriasis and depending more and more on chrysarobin. He has found by experimentation that a 20 per cent. mixture of chrysophanic acid and petrolatum can be safely applied to one-third or even more of the entire cutaneous surface without serious local or constitutional disturbance. The ointment he applies by means of a stiff toothbrush twice a day, the patient being kept in bed and the eyes bandaged at night, and he has found seven days a sufficient time on the average. Afterwards he gives arsenic.

At the same meeting O. H. and H. R. Foerster⁶ of Milwaukee recorded their observations on a new method of Roentgen-ray therapy in psoriasis. The method is that described by Walter Brock of Kiel University and originated in an observation by Brock that a child with psoriasis, especially of the head and chest, de-

veloped an extensive and severe outbreak while under treatment with Roentgen-rays for local effect. Experimentation instigated by this led Brock to the conclusion that irradiation of the thymus gland, with careful attention to its surface topography, leads to the disappearance of the lesions of psoriasis in from one-half to two and one-half months under certain conditions. An overdose was found to be followed by an active development of the affection. Brock explained the action of this method of treatment by assuming that psoriasis is associated with hypofunction of the thymus, which can be temporarily overcome by stimulation with Roentgen-rays. The Foersters' observations concerned 23 patients and extended over a period of five months. Eleven patients were given a second dose after two months, and two received a third dose. The original paper should be referred to for the details of the treatment. In most of the cases that responded to treatment there was a slight elevation and congestion of the lesions within a few days, and after 8 to 12 days the lesions involuted rapidly; in several cases large thickened plaques of long standing disappeared completely in four weeks. In 13 of the 23 cases the condition was at least markedly improved. In eight most of the eruption disappeared entirely; in five there was complete clearing up, three of the five showing a recurrence after varying interval. The writers, as a result of their investigations, regard this method as one that produces favorable, although apparently temporary, results in a sufficient number of cases to warrant its position as a practicable procedure in treating psoriasis.

In the discussion that followed the reading of these papers, Dr. G. H. Fox of New York emphasized the superiority of the old chrysophanic acid that was in the market 40 years ago, to the chrysarobin of today. It was the prevailing opinion that the etiology of psoriasis is still as obscure as ever. Also that a low protein diet often exerts a marked influence on an eruption of extensive psoriasis. Schamberg stated that he had never claimed that a metabolic error was the cause of psoriasis, but that diet has a most important bearing on its course. He thinks that no remedy, either external or internal, will exert a favorable influence in the stage of eruptive activity. We must bend our energies to converting an active into a quiescent psoriasis, and he considers that two methods are capable of bringing this about: a low protein diet and autoserum injections. When the eruption has become quiescent it may disappear under various internal and external agencies.

OIL FOLLICULITIS.

Page and Bushnell's⁷ paper is concerned with the skin affection due to oils, and particularly with those due to the use of machine oils, their interest in this subject being aroused by

an investigation undertaken to find the cause of an epidemic of furunculosis among those employed in a machine shop. As in the case of machine oil, the disturbance seems to be largely due to a mechanical plugging of the follicles, followed by inflammation and infection, and they therefore suggest the name oil folliculitis. After a comprehensive historical review of skin affections produced by oil, the type of lesions, and influences predisposing to infections of the skin, the writers declare that very little attention has been given to the bacteriology of oils. The bacillus subtilis and the usual pus-forming organisms have been reported found. The writers in their experimental work isolated the following organisms: Type I *Bacillus aerogenes*; Type II *Bacillus coli communis*, both of fecal type; also Type III, which was a Gram-negative, non-spore forming, active motile rod, very similar to the liquefying *Proteus vulgaris* strains. The following is a summary of the writers' conclusions:

1. Oils of all types are likely to produce skin affections if they come in contact with the skin for some length of time.
2. The most serious skin diseases are probably due to the oil acting as a carrier of infectious material from one individual to another.
3. Individuals of the most cleanly habits are, generally speaking, least liable to skin affections due to oils.
4. Special care should be exercised by workmen on cutting machines to avoid contamination of the oil, especially by saliva.
5. Individuals having skin diseases should be transferred to some other type of work.
6. While oils may be placed on the market in a sterile condition and free from dust, etc., they will not long remain so after being put in use.
7. By heating the oil to 70° C. for 20 or 30 minutes it is possible to destroy all the dangerous pathogenic bacteria likely to be present.
8. It would seem very desirable to use oil which has been rendered free from dust, and especially from particles of metal.
9. Workmen should not exchange waste and rags used in cleaning their hands, and should not bathe their hands in the oil.
10. Clothing saturated with oil should not be worn, especially if there is an epidemic of skin diseases among the workers.

INJURIOUS COMBINED EFFECT OF ROENTGEN-RAYS OR RADIUM AND TOPICAL REMEDIES.

MacKee and Andrews' point out that physicians, even those who do not employ x-rays and radium, should understand the dangers that attend the association of these forms of treatment with irritating topical applications.

Irradiation, whether or not followed by visible reaction, increases the sensitiveness of the skin to irritating agents. Small doses of Roent-

gen-rays or radium combined with strong local irritants may result in severe injury, as may also large, although safe, doses of Roentgen-rays or radium combined with mild topical irritants. But intensive irradiation associated with strong topical irritants is the combination most likely to produce injurious results. Ordinarily the skin, when there has been no visible reaction or permanent injury, will react to topical remedies in one month. If there has been a reaction the skin is likely to remain sensitive for months or years, and in cases where there has been permanent injury, telangiectases, atrophy and scarring may result. Fractional irradiation is cumulative in effect, and the degree of hypersensitiveness of the skin will depend on the size of the individual doses and the interval between the applications.

The topical application of stimulants, irritants and caustics makes the skin hypersensitive to irradiation, the degree depending on the strength of and method of applying the topical remedy, and also on the time interval between the application of the topical remedy and the irradiation. Any drug that is capable of causing an inflammatory reaction in the skin may make it more susceptible to irradiation. Among these may be mentioned chrysarobin, scarlet R medicinal, iodine, mercury, resorcin, tar, sulphur, salicylic acid, etc. The writers assert that they cause the least trouble when used as powders, more when in solution, and the most as ointments. Caustics, as acid nitrate of mercury, zinc chloride, nitrate of silver, etc., may increase the effects of irradiation, as well as ultraviolet light and refrigeration, especially the latter. The combined effect of irradiation and topical stimulants, irritants or caustics produces a reaction that is, as a rule, indistinguishable clinically and pathologically from radio-dermatitis.

After citing eight cases in illustration, the writers come to the following conclusions: Roentgen-rays and radium may make the skin hypersensitive to stimulating, irritating and caustic agents locally applied. As a rule the skin will react normally to topical remedies in a month; but if there has been a reaction the hypersensitiveness may endure for several months, and if the skin has been permanently injured, the hypersensitiveness may be detected for a year or two, or even indefinitely. Stimulating, irritating and caustic remedies, when locally applied, produce hypersensitiveness to Roentgen-rays and radium for about a month. If the skin reacted to the local remedy, increased radio sensitiveness is the rule for one month after the complete disappearance of the reaction. A physician about to prescribe topical applications of an irritating nature should first ascertain whether the parts to be so treated have been recently irradiated or are to be irradiated. A physician about to apply Roentgen-rays or radium to a patient should first ascer-

tain whether irritating topical remedies have been recently used; and the patient should be cautioned against additional local treatment without the knowledge and consent of the physician who applied the Roentgen-rays or radium.

UNUSUAL HERPES ZOSTER."

Corson and Knowles of Philadelphia state that herpes zoster has been reported to occur in between one and two per cent. of all diseases of the skin, usually nearer the smaller figure, and is pretty constant both in Europe and in America. In certain periods it is seen with great frequency, so that it amounts almost to an epidemic; at other times it may be very seldom met with. There are certain vagaries and interesting atypical cases occasionally seen.

By some a relationship of this affection to varicella has been discussed, by others the meaning of the rare general eruption accompanying it, as well as the exceptional paralysis coexisting with the outbreak, a bilateral distribution, and its occurrence on the same side at a distance. The last is quite uncommon. In a few cases cranial and spinal nerves have been affected at very distant places.

Two cases are reported: one, that of a housemaid of 50 years, whose mental processes were confused and whose speech was slurred. The superior rectus and the elevator of the upper lid were paralyzed; she was by turns delirious or stuporous, and it was thought that she had bulbar lethargic encephalitis. She had been taking Fowler's solution for about five weeks when she developed a zoster over the posterior aspect of the right thorax, and also on the right side of the forehead. In this case the arsenic may have been a causative factor, as there are many well-known instances of zoster following the ingestion of this drug. A motor paralysis is a more frequent occurrence with zoster. Greenough saw it but twice in 255 cases of this affection.

The second case is that of a man of 26, who presented the eruption on the left side of the face and also in the supraclavicular, infraclavicular and suprascapular regions of the same side. There was also a left facial paralysis, which was said to have appeared at the same time as the eruption. The patches on the face were situated in front of the ear, and, lower, over the ramus and body of the mandible in the area supplied by the third cervical root, while the eruption over the clavicle was entirely in the area innervated by the fourth cervical root.

The writers' conclusions are that in the cases of herpes zoster associated with facial paralysis, the geniculate ganglion has uniformly been found inflamed, when examined. The sensory ganglions affected in this case were the third and fourth cervical. While it is customary for only one ganglion to be involved, Hunt says: "It is probable that two ganglions are occa-

sionally affected together. From clinical observation this seems particularly liable to occur with the second, third and fourth cervical." In Hunt's table of types of eruption found in the 80 cases associated with facial paralysis, only one was of the combined facial and occipitocollaris distribution.

Book Reviews.

The Venereal Clinic: The Diagnosis, Treatment and Prevention of Syphilis and Gonorrhoea. By several writers. Edited by Ernest R. T. Clarkson. Wm. Wood & Co. 477 pp. Price \$6.50.

This handbook of venereal disease, by a number of English writers, consists of a Section on Syphilis by A. Malcolm Simpson, Henry C. Semon and James H. Sequeira; a Section on Gonorrhoea in the male by E. R. T. Clarkson, W. Wyndham Powell and A. Malcolm Simpson; a Section on Gonorrhoea in the female by M. Rawlins; one on Gonococcal Affection of the Eye by Alex. Bruce Roxburgh; one on Bacteriology by Philip Panton; and Part Two, on the Sociological and Administrative Aspects of Venereal Disease, by E. R. T. Clarkson and H. S. Q. Henriques.

Beyond a doubt the medical profession in England is handling the venereal disease question with more candor and serious thought than is shown by medical men in this country. Perhaps the problem is more acute in England.

This book reflects the British attitude; it is original, honest and fully awake to the broader relations of venereal disease. One finds in it, not a hackneyed account of the period of incubation and prevailing symptoms, but a full discussion of those mooted questions in diagnosis and treatment upon which there is still divergence of opinion. It is a book which can be read with profit even by experienced venerologists.

Part two deals with venereal disease in the community, the prevention of venereal disease, adjuvant societies and institutions, the relation of the medical man to patients in a venereal disease clinic, and legislation and the practitioner. Valuable information upon these general aspects of venereal disease is presented in concentrated form. The book should be very helpful to social workers, public health officials, and to all medical men who have anything to do with venereal disease.

Aids to Bacteriology, by Wm. Partridge, Fourth Edition, Wm. Wood & Co., New York.

This is a small compendium of bacteriology, without particular merit. It is not illustrated. The size of the volume permits it to be carried in the pocket, and for that reason it might be useful for students engaged in cramming for an examination. The work could be duplicated by taking any good text-book of bacteriology and condensing it, and it has naturally the defects which go with such a process. However, in Chapters 20, 21 and 22, we have sixty-two pages devoted to the bacteriology of food-stuffs and water, and disinfection and disinfectants. This portion of the book approaches excellence.

Hyperpnea and Hyperpnea. A Clinical, Pathological and Experimental Study. By H. BATTY SHAW, M.D., F.R.C.P., Physician to University College Hospital, etc., etc. Dedicated to Rt. Hon. Sir Clifford Allbutt, Oxford Medical Publication, Henry Frowde and Hodder & Stoughton, London, 1922. Pp. 191 with illustrations, tables and charts.

As its title implies, a critical study of hyperpnea, its nature, origin, relation to nephritis and treatment based on clinical and postmortem evidence of 50 fatal cases exhaustively studied.

The introduction carries a brief discussion of some of the prevalent theories and a statement of the problem. Section one gives clinical history, gross pathology and microscopic kidney pathology of the 50 cases used as a basis of the study. Section two follows with a careful analysis of clinical details. Section three considers the origin of hyperpnea and idiopathic cardiac hypertrophy. The fourth section is somewhat technical; describes the experimental study of the search for a pressor substance which acting through the blood stream could cause a rise of blood pressure. Section five, the last, has to do with conclusions and therapy.

As an example of careful and painstaking research, orderly presentation, and sane discussion of present theories and known facts in relation to the author's work, it is hardly possible to say too much in its commendation. As an example of fine book making and in its illustrations it is equally good.

On the whole one of the really worth while books of the year, particularly to one interested in the problems of internal medicine.

The Treatment of Ordinary Diseases. From the Note Book of an Old Practitioner. By BEVERLEY ROBINSON, M.D. (PARIS), Emeritus Clinical Professor of Medicine at University and Bellevue Medical College, N. Y. Pp. 130, New York American Medical Publishing Co.

Rather pleasant little book discussing in a conversational and non-technical manner most of the common ailments from the ordinary cold

to Colles' fracture with an almost startling superficiality.

It is for its interest as "the note book of an old practitioner" rather than a text-book on "the treatment of ordinary disease" that its value, if it has any value, lies.

While the man with well grounded opinions in medicine may have a pleasant hour or two, a book which recommends that acute middle ears be not opened but allowed to perforate; that decries the operation for acute appendicitis; that regards digitalis as no particular value but teaches the great value of strophanthus and who recommends antitoxin in the treatment of diphtheria but whose only advice as to dosage is to avoid too large a one is hardly a book to put into the hands of a medical student.

In short in the opinion of the reviewer it will find few appreciators except those who may have known and loved the author.

Disease of the Thyroid Gland. ARTHUR E. HERTZLER, M.D., F.A.C.S., St. Louis; C. V. Mosby Co., 1922.

This book, as the preface states, represents an effort to bring before the public the results of studies of a particular disease in a small country hospital. The material collected has been carefully studied and compared with the clinical history and each subsequent examination of the patient has been checked by a re-examination of the specimen and slide. The author reaches the conclusion that convincing evidence is obtained to indicate the association of the activity of the interstitial cells with a definite clinical type of thyroid intoxication.

The subject is presented from the viewpoint of a clinical surgeon dealing practically with the thyroid problems. The symptoms of thyroid disease and accepted methods of treatment are described at considerable length though the author fails to mention some of the newer details of treatment. For example, under the head of vocal cord paralysis there is no mention of the operation. Ventriculocordectomy, recently recommended by Chevalier Jackson for the relief of abductor paralysis. Likewise under tetany there is no discussion of the subject of parathyroid therapy, and under myxoedema no mention is made of the method of checking the administration of thyroid extract with estimations of the basal metabolic rate.

One experienced in thyroid surgery cannot fail to be in accord with the statement that "goiter in the adult is a dangerous disease and unless cured tends to destroy the life of the patient. The so-called innocent goiters, which frequently exist for ten to twenty years, usually sooner or later kill by undergoing toxic or malignant degeneration."

In his discussion of treatment the author makes a statement which is the basis of all success in thyroid surgery: "It is necessary that every therapist follow his cases and construct

for himself a series of experiences, for by this means alone can he develop the necessities of judgment so necessary to the successful treatment of goiter."

In the matter of anaesthesia the author states his preference for local anaesthesia, admitting his lack of experience with nitrous oxide. The almost parallel mortality obtained in different thyroid clinics where each uses a different type of anaesthesia, ether, local, gas oxygen and gas oxygen analgesia, should, in the opinion of the reviewer, lead to the selection of the anaesthetic which is most comfortable for the patient and least limiting to the operator.

The reviewer's experience has not been in accord with the following statement made in the discussion of Basal Metabolism: "Unfortunately the test is a difficult one to make properly and errors of technique too often come in to confuse results." Nor does the reviewer agree with the author's opinion that "a good laboratory man may be of much help to the inexperienced clinician. To the experienced surgeon the aid is relatively little."

As previously stated, the book presents the subject from a practical and generally sound point of view. It is well arranged, with numerous references to the literature and written in a very readable form. Its careful perusal would do much to clear up the confusion concerning thyroid diseases which undoubtedly exists in many medical minds.

HYPERTHYROIDISM.

MURRAY, G. R. (*British Medical Journal*, June 10, 1922) divides hyperthyroidism into three groups:

1. Simple hyperthyroidism.
2. Toxic adenoma of the thyroid gland with hyperthyroidism.
3. Exophthalmic goitre or Graves's disease.

He devotes himself particularly to the treatment of the third group—exophthalmic goitre.

The advantages of operative treatment are:

1. The saving of time by the rapid reduction of the hyperthyroidism and relief of the symptoms.
2. The diminution of the risk of irreparable damage to the heart in the form of the chronic myocarditis which develops in severe and in prolonged cases.
3. The complete and rapid recovery in some cases.

The disadvantages are:

1. The risk to life.
2. The uncertainty of the ultimate result owing to the difficulty in determining the right amount of the gland which should be removed in each case. For example, one of my cases had two partial thyroid-

ectomies performed, but at the end of ten years still showed marked symptoms of the malady, which finally subsided under x-ray treatment.

3. The tendency to recurrence at the end of a year. He believes that in any case medical treatment should have a full trial for six months. [J. B. H.]

THE DIAGNOSTICAL VALUE OF GASTRIC FRACTIONAL TEST MEALS.

EMBERTON, H. S. (*British Medical Journal*, July 1, 1922) discussing the value of fractional test meals in diseases of the stomach concludes as follows:

1. The acidty curves plotted from fractional test meals are of some value in obtaining knowledge of the factors which modify the acidity.
2. Alterations in these factors bear some sort of relation to gastro-intestinal lesions; hence the acidity curves may throw some light on these lesions.
3. These curves seem divisible into at least six types of varying diagnostic value.
4. By comparison with other methods the fractional test meal is at least admissible as an aid to diagnosis. [J. B. H.]

PULMONARY EMBOLISM AFTER OPERATIONS.

GORDON-WATSON (*The Practitioner*, June, 1922) finds in the surgical post-mortem records of St. Bartholomew's Hospital three cases of pulmonary embolism out of 594 during the years, 1912-1914, at an average age of 52, and nine cases of pulmonary embolism out of 538 post-mortems at an average age of 60 during the years, 1919-1921.

He then discusses the pathology of pulmonary embolism and its occurrence and discusses at great length the factors in its causation. He is a strong opponent of purging a patient prior to operation and believes that the Trendelenburg position and other abnormal positions of the body during operation may be factors in causing such pulmonary emboli.

[J. B. H.]

THE BONY FEATURES OF POSTERIOR CONGENITAL DISLOCATION OF THE SHOULDER.

TODD, T. W. (*Annals of Surgery*, July, 1922), writes as follows: Posterior congenital "dislocation" of the humerus, as illustrated in the Hamann Museum at Western Reserve University, provides the following information:

1. It is of the subacromial type and differs from pathological dislocation in the fact that the humeral head never leaves the glenoid surface.
2. It results from a mal-development confined to the scapula and not affecting the humeral head. The mal-development is in the dorsal part of the scapular neck, so that the glenoid surface is rotated on to the dorsum of the blade. Accompanying this is a drooping of the acromion over the shoulder.
3. Congenital "dislocation" is a high grade of the deformity just described, which, however, may be of slight development and unilateral or bilateral.

4. The condition was found in three white males only among a random sequence of 730 complete human skeletons distributed as follows: 489 white males, 66 white females, 143 negro males, 32 negro females.

5. In the collection just mentioned there is no case of congenital dislocation of femur or radius.

6. Posterior congenital dislocation of the shoulder is not a true dislocation since the humeral head never leaves the glenoid surface. It is undoubtedly "posterior" and all the evidence goes to show that it is really congenital in occurrence since it makes its appearance coincidently with the original scleroblastic formation of the scapula.

7. There is no inherent reason why this postural deformity should not be associated sooner or later with a nerve lesion. [E. H. K.]

TUMORS OF THE KIDNEY IN INFANCY AND CHILDHOOD.

MIXTER, C. G. (*Annals of Surgery*, July, 1922), presents a very interesting article based on a fairly large experience at the Children's Hospital in Boston with this type of case. His article is of much interest and considerable value. He emphasizes the frequency of malignant tumors of the kidney region in infancy, generally insidious in onset, and the strong tendency to recurrence, so that cure can only be expected by very early diagnosis and surgical removal. The confusion of kidney tumors with inter-abdominal tumors in infancy and childhood is also strongly emphasized. [E. H. R.]

TRANSPLANTATION OF THE ENTIRE FIBULA IN CASES OF LOSS OF THE TIBIA FROM OSTEOMYELITIS.

MACAUSLAND, W. R., AND SARGENT, A. F. (*Annals of Surgery*, July, 1922), present a very well illustrated article on this interesting subject. They describe the operative technique and present some very interesting x-ray plates. [E. H. R.]

OBSERVATIONS ON THE TREATMENT OF ACUTE PERFORATIONS OF THE STOMACH AND DUODENUM WITH REFERENCE TO GASTRO-ENTEROSTOMY.

WILENSKY, ABRAHAM O. (*Annals of Surgery*, July 1922), writes as follows: "In view of all of the facts outlined in this communication it seems to me that the most rational procedure in the presence of an acute perforation is to simply close the perforation. In a certain number this would be all that would ever be necessary. In others a course of medical treatment might be valuable before resorting to any extensive surgical operation. In still others, in which the continued presence or recurrence of post-operative symptoms would make it advisable, further surgical measures could be undertaken in the security of conditions not burdened with the risks of any emergency and with the added advantage of more prolonged pre-operative study and planning. Better and more adequate measures can thus be more securely employed." [E. H. R.]

THE FATAL OUTCOME OF CERTAIN CASES OF STAPHYLOCOCCUS INFECTIONS OF THE FACE AND LIPS.

MARTIN, W. (*Annals of Surgery*, July, 1922), presents an interesting but not very concise paper as the result of thirty years' experience with a fairly large number of these desperate cases. He does not draw any definite conclusions as to treatment, but speaks of various forms in an interesting manner. He emphasizes the often overlooked fact that thrombosis of the cavernous sinns often follows infections of the lip and that this is the cause of the fatal outcome and is of necessity most difficult to deal with. The use of any trauma to the infected area, such as squeezing or other efforts to express infectious material, should be strictly avoided. Attempts at aspiration should also be avoided. Ligation of the jugular is sometimes indicated in selected cases, but the results are not encouraging. The author reports eight case histories in detail and appends a very good bibliography. [E. H. R.]

HAMANGIOMAS OF THE GASTRO-INTESTINAL TRACT.

JUDE, E. S., AND RANKIN, F. W. (*Annals of Surgery*, July, 1922), write as follows: Angiomas of the gastro-intestinal tract are rare and may simulate malignant conditions. When they occur in the stomach they are generally found on the posterior wall in the common location for malignant conditions.

Similar to other benign tumors of the stomach, angiomas are occasionally found in young persons. There may be no definite gastric upset, the main

complaint being weakness and epigastric discomfort. The acid values of the gastric secretion are generally normal and the general condition of the patient is usually much better than that of the patient with a similarly located malignant lesion.

Angiomas of the stomach, while generally small, may grow to a very large size. They are usually soft and covered with mucous membrane. Histologically, they are composed of fine blood-vessels and masses of fibroblasts and endothelial cells.

At the Mayo Clinic three patients with angioma of the stomach and one with angioma of the duodenum have been operated on in the past two years; two of the patients were young, and two were of cancer age. The advanced age of these two patients and the Roentgen ray findings, similar to those in malignancy, suggested inoperable malignant lesions.

In all cases the tumor was removed and operation was followed by an excellent immediate and late result. [E. H. R.]

NEURORECIENCES FOLLOWING TREATMENT WITH ARSPIENAMIN.

ZIMMERMAN, ERNEST (*Archives of Dermatology and Syphilology*, June, 1922), says: From the opening of the Syphilis Clinic of the Johns Hopkins Hospital in 1914 to September 1, 1921, 7055 syphilitic patients have been treated. Of these, 1400 were primary or early secondary cases. In this group, neuroreurrences have occurred in 23, or 1.64 per cent. Sixteen additional cases are included in this report, comprising patients who received initial treatment elsewhere and had already developed symptoms of neurosyphilis at the time of their first visit to the clinic, and those seen in the Syphilis Clinic of the Baltimore Eye, Ear, and Throat Charity Hospital.

Dr. Zimmerman tabulates the sum of these cases, which is 39, and discusses their symptomatology, genesis, and prognosis. He finds that pathologically there are two types: a diffuse meningovascular process, and a process limited to one or more focalized lesions. In the former the spinal fluid is always abnormal, in the latter it may show marked abnormality or it may be entirely normal. Prophylaxis of such lesions depends on thorough mercurial treatment. It seems immaterial whether mercury is administered during or immediately following a course of arsphenamin.

INJURY OF THE LIMBS DUE TO BACK-FIRE.

BIZARRO, A. H. (*Annals of Surgery*, July, 1922) draws the following conclusions:

1. The lower third of the radius and ulna is the commonest seat of back-fire fracture, and the carpal bones the next common.
2. The crack through the epiphyseal line of the radius is the commonest type of single bone lesion.
3. The ulna styloid tip and radial epiphyseal line are the commonest type of double bone lesions.
4. The scaphoid is the commonest carpal bone involved.
5. In individuals under twenty years of age the diagnosis of ulna styloid fracture is more difficult owing to the common occurrence of irregularities of ossification.
6. In twenty-five per cent. of the cases of the series the injury of the wrist was limited to the soft parts.
7. The upper end of both radius and ulna are occasionally the seat of fracture.
8. The age of the individual has no bearing on the fracture being at the epiphyseal line.
9. The great bulk of these injuries is of the indirect type.
10. The prognosis is usually good.

[E. H. R.]

THE BOSTON Medical and Surgical Journal

NUTRITION AND GROWTH IN CHILDREN.

The Great War had many unexpected by-products. Some of these have proved to be of great importance in advancing the public health movement. For example, it is seldom that a nation has received a greater shock than that which came to America when the figures were published showing the armies of young men who had been rejected from military service on account of physical unfitness.

It was very natural to turn from this startling picture to the growing children in order to see what conditions are found among them. Even the superficial results secured by understaffed and poorly equipped systems of school medical inspection are found to furnish striking confirmation of the discoveries that were made through the army examinations.

Many physicians, teachers and social workers have long been alarmed by the numbers of children whom they have found to be in need of care and yet not sick enough to require hospital treatment or to be put in bed. These children are clearly under par and unequal to the day's work and enjoyment that belong to them at this time of life. Open air and other special class rooms as well as school lunches have been provided for them. They congest the clinics and are labelled "Run down," "No appetite," "General debility," "Needs a tonic," and yet nothing is done for them. There is nothing

definitely known to be the matter with them and yet everything about them seems to be wrong.

Fortunately there have been clinical studies in operation for a number of years which have blazed a path through this obscure situation. The results of these studies, however, up to the time of the war, had made comparatively little impression upon the public or even upon the members of the medical profession. The condition was sensed only in part—the means of correcting it were not yet appreciated and it was all too easy to fall back upon the vague hope that although a particular child did not seem to be in fit condition "he would outgrow it!"

It had been taken for granted in many situations that the causes of malnutrition were known and understood. Popular opinion favored poverty and insufficient food as the most reasonable explanations, but in nutrition clinics investigation of thousands of children showed that these causes, like many others commonly assumed to be significant, are only secondary and fail to explain the greater number of cases. Many causes have been discovered, but the great majority were found to fall into five fundamental groups: (1) physical defects, especially inflammatory processes of the naso-pharynx; (2) lack of home control; (3) over-fatigue; (4) faulty food habits, with improper and insufficient food; (5) faulty health habits.

It is also clear that although many symptoms are found, practically all of these children show a common characteristic of insufficient body weight in proportion to height. The next step has been to find the limits of variation in weight which mark out the boundaries of what might be considered a zone of weight safety. Clinical observation was first concerned with an average weight line determined by weighing and measuring some hundred thousand American children. Ten per cent. underweight for height was taken as a trial standard, but it was very soon evident that this basis allowed many children needing care to be included within the normal zone. Individuals were observed as they passed beyond this limit and remarkable correlations were evident between changes in weight and various physical and psychical conditions. These studies placed the lower limit of weight safety at about seven per cent., which is practically a year's growth, and it has been found that no child who is habitually this amount below the average fails to show clearly other evidences of malnutrition.

This method furnishes a convenient way by means of which at least 90 per cent. of the children needing care for malnutrition can be identified. Further work upon the causes has developed a nutrition program which has proved applicable to the varying conditions of city and rural life and is in successful operation from Labrador to the Gulf of Mexico and from Boston to Honolulu. An important feature of this nutrition program is the use of the class method

which brings into coöperation the four forces which are essential in dealing with malnutrition: (1) the home; (2) medical care; (3) the school, and other social agencies; (4) the child's own interest. This class or group method for the treatment of malnutrition, as originated and developed by Emerson in this city, has been characterized by Holt as "epochal in the treatment of children."

President Eliot has recently emphasized the necessity of providing for experimentation by independent, private organizations free to work out new lines of attack and development which can be taken over by the state and local community after successful demonstration has proved that they are advantageous. A national society, Nutrition Clinics for Delicate Children, with headquarters in Boston, has made demonstration in leading cities in every section of the country of a program by means of which a large proportion of these malnourished children can be brought back to normal health within a few months' time with such food and health habits established as will keep them there. The school authorities and other community forces are extending the work so that it may reach all children.

But the responsibility of the medical profession does not stop at this stage of development. There are cases to be detected among children who are temporarily malnourished without showing any loss of weight as yet. There are also individuals who require investigation for a period of months and even years before the hidden causes of their malnutrition are disclosed. With proper organization a physician can keep three-quarters of the members of a class of twenty gaining steadily by the expenditure of half an hour of his time each week, but the other fourth furnish a constant challenge to the best results that his training and experience have given him as well as contact with the most effective aids he can secure from specialists in many fields.

The next step in bringing this large proportion of our children of school and pre-school ages up to normal health conditions—a striking challenge to those who seek to forward preventive medicine—lies in providing adequate teaching of the subjects of nutrition and growth in medical schools.

Loss in weight taken by itself may be an early symptom of phthisis, appendicitis, pyelitis, sinusitis, chronic tonsillitis, and other inflammatory processes secondary to naso-pharyngeal obstruction. It is also a sign of such organic defects as deviated septum, intestinal adhesions, and reflex disturbances such as cardio-spasm and anaphylaxis due to protein sensitization. It may likewise be a symptom of toxemias secondary to focal infection, gastric and intestinal indigestion, overfatigue, bad air, lack of sunlight, drug habits and the deficiency diseases.

Physicians in general practice and even pediatricians have been slow to realize that malnu-

trition and failure to make normal growth are fundamental medical subjects. In consequence this large group of malnourished children, from whose ranks the daily total of more evident illness is recruited, is left to the tender mercies of school nurses, dietitians, social workers, and, to an increasing extent, the chiropractor and the osteopath.

Even a brief experience with the working of a nutrition program will show the fallacy of the common excuses made for neglecting this field and will convince the medical student that malnutrition is a serious medical problem which demands the skill of the best trained physician. Early diagnosis is the most valuable form of preventive work, and is as much a test of skill as is late diagnosis when the condition has progressed to a more serious or critical stage.

No pediatrician would fail to be concerned when an infant ceases to gain in weight and begins to fall away from normal standards, or when he shows pallor, flabby tissues and the least sign of deformity. Yet these symptoms pass unnoticed and uncorrected in older children when they have great significance during the entire growing period. Instead of discouraging the mother who is seeking an examination for her child, the physician should be trained in his college years to expect to lead rather than to follow in this important means of detecting pathological conditions. A great step will be taken in asserting the positive function of the physician when we may expect to have every child given a complete physical-growth examination each year during the period of his growth.

These examinations should be given in the presence of the child's parents and every effort should be made to help them understand the meaning of the defects which the examination discloses. The physician finds that one of the chief advantages of the nutrition class method is that by this means he has weekly opportunities to instruct mothers in the application of health education to conditions appearing in the group of malnourished children. It is in this direction that we must move until the excellent care now given to infants shall be afforded to the pre-school and school periods as well as to growing youth after his entrance into industrial pursuits and college.

The successful accomplishment of this nutrition work has shown clearly that the problem cannot be solved by means of any single line of attack. There must be a thoroughgoing community program, which means that medical service must be tied up closely with social and educational service—that is, with home and school. This will result in health education not only for the children but also for parents and public as well. To accomplish this end Nutrition Clinics for Delicate Children is holding institutes in various parts of the country with the purpose, on the one hand, of training physi-

cians, nurses, and health workers in the special medical and social technique required in the undertaking and, on the other, of securing the intelligent interest of parents and educational and health authorities, so that the work may be supported adequately and become a permanent factor in community health and life. Beginning in Boston, institutes of this kind have been held in ten states and from these as centers have reached practically every state in the union.

THE CURE OF DISEASES THAT HAVE RESISTED MEDICAL RESOURCES.

AND now comes Congressman Sproul and suggests that the government shall offer a prize of one million dollars for the discovery of the cure of any one of the following named diseases: Tuberculosis, pneumonia, cancer, epilepsy and dementia praecox. Without the honor of a personal acquaintance with Mr. Sproul, one may assume that the motive which prompted this suggestion was activated by sympathy for the hundreds of thousands of sufferers afflicted with these diseases and an appreciation of the economic burden on the nation imposed by disability and loss of productive human life. Thus far one may sympathize with the member of Congress, but distrust of his judgment is in order for the suggestion of the appropriation of these large sums of money carries to educated physicians serious doubt as to the intelligence of the proponent. He may be a good politician, or even a statesman, in dealing with political problems, but he has gone far wide of the mark in his effort to cure these diseases.

This proposition suggests the thought that some persons have an exaggerated estimate of the value of money and a particularly poor conception of its proper expenditure. Some minds infer that the great accomplishments achieved through spending money in some ways warrant the expectation that if sufficient money could be used almost anything would respond to the magic touch of gold. This attitude is one of the unfortunate effects on those minds that have been dazzled by exhibition of the lavish use of money.

There are other features of such proposals which will arouse a feeling of indignation in the minds of most of our scientific workers, for although recognition of meritorious work and the conferring of a dignified honorarium are appreciated by all benefactors of the race, such an offer would not add one particle of energy to scientific investigation. As a rule, great discoveries in medicine have been made by persons possessed of vision and determination, actuated by altruistic motives and controlled by scientific minds. If a million dollars a year could be devoted to the support of those institutions in which research is already being carried on, the

investment would be more to the purpose. One may fear, on the other hand, that some impostor may prey on the credulity of the representatives of the government, as has been done, it is feared, in another country. Instead of stimulating valuable effort the exploiters of turtle serum or our later aspirant for fame, Abrams, and a host of other claimants would lay siege to the treasury, supported by affidavits and personal testimony. Any honest believer in any cure can submit evidence of his claim to impartial analysis and be sure of fair treatment.

Whenever the government is ready to appropriate millions to be used by scientists there will be found many opportunities for aiding existing reputable organizations. An honest ambition to benefit the race is commendable, but all efforts along these lines should be under the guardianship of well-trained minds, endowed with capacity for correct reasoning.

COMMUNICABLE DISEASES AND SCHOOL ATTENDANCE.

THE reports of Boards of Health for the ensuing two months will be of interest for, if the predictions which have repeatedly been made, that with the opening of schools the number of communicable diseases often show a marked increase, shall prove to be the rule, it will indicate that the health of the scholars has not been carefully supervised.

Parents and physicians should exercise care in determining the character of even slight indispositions before sending children to school. It has been a somewhat common practice to try and get a child suffering with some disorder ready to enter at the appointed date and there is, at times, a well-recognized risk to other pupils in the segregation of well and sick children. Even though a child may be improving he may be harboring the germs of a communicable disease and it is quite impossible for school physicians to cull out all of the doubtful cases. Parents should be instructed that a physician's advice should always be sought before allowing a child in a doubtful condition to go to school. More care is exercised now than formerly, but statistics will indicate the degree of prudence that prevails.

NEWS ITEMS.

MASSACHUSETTS ASSOCIATION OF ASSISTANT PHYSICIANS. — The first Midsummer Outing of the Massachusetts Association of Assistant Physicians was held at Nantasket Beach on Friday, August 25, 1922. A total of forty-six members attended. The party enjoyed an excellent shore dinner at the Nantasket Hotel where special arrangements had been made for

their entertainment. After dinner a business meeting was called to order by the President, Dr. R. M. Chambers. It was proposed by Dr. H. M. Watkins that the outing be made an annual affair, and the consent to this was unanimous. Following adjournment, the members threw aside the mantle of professional dignity and found themselves rewarded by an afternoon of unalloyed enjoyment.

Neil A. Dayton, M.D., *Secretary*,
Wrentham State School.

DR. CHANNING FROTHINGHAM'S TREATISE ON THE CULTS.—Dr. Bertram Bryant, Secretary of the Maine Medical Association, has sent Dr. Frothingham's treatise on Osteopathy, Chiropractic, and the Profession of Medicine, taken from the *Atlantic Monthly* of July, 1922, to all of the physicians in Maine, in order to enable them to discuss the questions involved intelligently. Much of the substance of this article has appeared in Dr. Frothingham's report in the JOURNAL, under date of Dec. 15, 1921, and in an editorial in the issue of May 19, 1921. All physicians should read Dr. Frothingham's treatise in order that proper influence may be used when these matters are before the legislature.

WEEK'S DEATH RATE IN BOSTON. — During the week ending Aug. 26, 1922, the number of deaths reported was 170 against 174 last year, with a rate of 11.61. There were 34 deaths under one year of age against 38 last year.

The number of cases of principal reportable diseases were: Diphtheria, 67; scarlet fever, 12; measles, 26; whooping cough, 46; typhoid fever, 5; tuberculosis, 40.

Included in the above, were the following cases of non-residents: Diphtheria, 9; scarlet fever, 3; tuberculosis, 5.

Total deaths from these diseases were: Diphtheria, 1; measles, 1; whooping cough, 4; tuberculosis, 11.

Included in the above, was the following case of a non-resident: Tuberculosis, 1.

Miscellany.

SECOND ANNUAL CLINIC FOR MAINE PHYSICIANS.

THE Second Annual Clinic for Maine Physicians, under the auspices of the Maine Public Health Association, the Maine Medical Association, Maine State Department of Health, and the Medical Societies of Androscoggin, Franklin, and Oxford Counties, was conducted Wednesday and Thursday, August 23d and 24th, at Lewiston.

Clinics were held each day at 10:00 A.M. On Wednesday medical and surgical clinics were

held at St. Marie Hospital, at which Dr. Joseph H. Pratt and Dr. Daniel Fiske Jones, both of Boston, lectured and gave demonstrations. On Thursday Drs. Pratt and Jones conducted similar clinics at the Central Maine General Hospital. Selected groups of cases at each hospital furnished material of special interest to the visiting physicians. At the close of each morning session a dainty luncheon was served by the nurses of the hospital.

Each afternoon beginning at 2 o'clock meetings were held at Chase Hall, Bates College, at which papers were read by State and National health officials. Wednesday afternoon health activities were considered from the standpoint of several administrative divisions of the State Health Department. The central topic of the evening was Co-operation, which was considered from three angles—the State Health Department, the Volunteer Agency, and the Medical Profession.

Thursday morning at 9 o'clock public health nurses who had been in attendance at many of the clinics were given a special program at Chase Hall, in which papers were read touching especially on problems arising in this field.

The program of Thursday afternoon was given over to papers on such special subjects as Tuberculosis, Ophthalmology, Mental Diseases, Cancer, Dental Hygiene, and the relationship of each to the public health program.

The two-day session was brought to a close by a dinner at 6:30 Thursday evening at Chase Hall. Dr. John Sturgis, President Androscoggin County Medical Society, presided. The speakers of the evening were Dr. Eugene Kelley, Massachusetts Health Commissioner; Dr. Langdon Snipe, President Maine Medical Association; Dr. E. D. Merrill, President Maine Public Health Association; Dr. Clarence F. Kendall, State Commissioner of Health for Maine; Dr. Clifton Gray, President Bates College; Drs. Joseph H. Pratt and Daniel Fiske Jones of Boston; and Dr. D. B. Armstrong of New York.

The program of the two days in detail follows.

AUGUST 23d.

10:00 A.M. Medical Clinic, St. Marie General Hospital. Clinician in charge, Dr. Joseph H. Pratt of Boston. Surgical Clinic, St. Marie General Hospital. Clinician in charge, Dr. Daniel Fiske Jones of Boston.

2:00 P.M. General Meeting, Chase Hall, Bates College; Chairman, Dr. Clarence F. Kendall, State Health Commissioner. Address of Welcome, Hon. Louis J. Brann, Mayor of Lewiston; Hon. Charles S. Cummings, Mayor of Auburn. "Functions of a State Department of Health," Dr. F. N. Whittier, Brunswick, Member Public Health Council. "The District Health Officer—His Duties and Opportunities," Dr. E. P. Goodrich, Lewiston, Health Officer for the Second Maine District. "The Relation of Social

Hygiene to Community Health." Dr. George H. Coombs, Director Division of Social Hygiene, State Department of Health. "The State Laboratory—How It May be Used," Dr. John Hewat, Director Division of Diagnostic Laboratories, State Department of Health. "Relation of Vital Statistics to the Mortality Rate," Florence S. Choate, Ph.D., Director Division of Vital Statistics, State Department of Health.

8:00 P.M. General Meeting, Chase Hall, Bates College. Chairman, Dr. Langdon Snipe, Bath, President Maine Medical Association. "Co-operation in Health Work from the Standpoint of the State Health Department," Dr. Eugene R. Kelley, State Health Commissioner for Massachusetts. "Co-operation in Health Work from the Standpoint of the Volunteer Agency," Dr. Donald B. Armstrong, New York, Executive Officer National Health Council. "Co-operation in Health Work from the Standpoint of the Medical Profession," Dr. Bertram L. Bryant, Bangor, Secretary Maine Medical Association.

AUGUST 24TH.

9:00 A.M. Meeting for Public Health Nurses, Chase Hall, Bates College. Chairman, Miss Edith L. Soule, Director Division Public Health Nursing and Child Hygiene, State Department of Health. "The Value of National Organizations to Local Associations in Child Health Work," Dr. Donald B. Armstrong, New York, Executive Officer National Health Council. "The Child Problem As Seen from the Viewpoint of the State Board of Charities and Corrections," Gertrude E. Hall, Ph.D., State Board of Charities. "Pure Food and Its Relations to the Health of the State," A. M. G. Soule, Chief Division of Inspection, State Department of Agriculture. "Child Welfare Work a Preventive Health Measure," Dr. Eugene R. Kelley, Boston, State Health Commissioner for Massachusetts. "Dental Demonstration, Red Cross Headquarters," Dr. Irving Pendleton and Miss Louise McLoon.

10:00 A.M. Medical Clinic, Central Maine General Hospital. Clinician in charge, Dr. J. H. Pratt of Boston. Surgical Clinic, Central Maine General Hospital. Clinician in charge, Dr. Daniel Fiske Jones of Boston.

2:00 P.M. General Meeting, Chase Hall, Bates College. Chairman, Dr. E. D. Merrill, Foxcroft, President Maine Public Health Association. "Tuberculosis—its Causes, Prevention and Cure and the Fight Against It as Part of a General Public Health Program," Dr. Francis J. Welch, Portland, Chairman Tuberculosis Division, Maine Public Health Association. "Preventable Eye Disorders," Dr. S. Judd Beach, Portland, Chairman Eye Division, Maine Public Health Association. "Mental Diseases from a Public Health Standpoint," Dr. Forrest C. Tyson, Acting Chairman Mental Hygiene Division, Maine Public Health Association. "Establishment of

Cancer Clinics in Various Public Hospitals in Maine," Dr. E. H. Risley, Waterville, Chairman Cancer Division, Maine Public Health Association. "Dental Hygiene—Its Relation to a General Public Health Program," Dr. Archer Jordan, Auburn, Chairman Dental Hygiene Division, Maine Public Health Association. "The Several Elements in a Broad Program of Public Health Work," Dr. Donald B. Armstrong, New York, Executive Officer National Health Council.

6:30 P.M. Dinner Meeting, Dr. John Sturgis, President Androscoggin County Medical Society, presiding. Speakers—Dr. Eugene Kelley, Dr. Langdon Snipe, Dr. E. D. Merrill, Dr. Clarence F. Kendall, Dr. Clifton Gray, Dr. Joseph H. Pratt, Dr. Daniel Fiske Jones, Dr. D. B. Armstrong.

Representatives from nearly all sections of the State were present and great interest was taken in all the features of the meeting.

THE GORGAS MEMORIAL FUND.

At the St. Louis Annual Session the Board of Trustees reported to the House of Delegates that in response to a request received from the directors of the Gorgas Memorial Institute of Tropical and Preventive Medicine for the coöperation of the American Medical Association, the Board had taken action which resulted in the appointment of a committee, representing the American Medical Association, to act on the project. The following were appointed: Dr. George E. de Schweinitz, Philadelphia; Dr. Charles W. Richardson, Washington, D. C., and Dr. Fred B. Lund, Boston.

The House of Delegates unqualifiedly endorsed the Gorgas Memorial as a tribute to a past President of the organization and one of its most distinguished and loved members. At its recent meeting the Executive Committee of the Board of Trustees received the following statement from the committee and directed its publication:

STATEMENT AND APPEAL FOR CO-OPERATION.

As a result of the stimulating suggestion of President Porras of Panama, it has been resolved that a fitting memorial shall mark the humanitarian service of the late Major General William C. Gorgas, and the beneficent influence of his life and work on mankind throughout the world. Following the thought of President Porras, it has further been decided that this memorial shall take the form of a scientific institute for the study of tropical diseases and of preventive medicine.

No better place could have been selected than Panama City, the gateway between the Atlantic and the Pacific, where General Gorgas' well-planned and executed work made possible the building of the Panama Canal.

It is hardly necessary to call the attention of the medical profession to the far-reaching effects of General Gorgas' work on the welfare of the people of the whole world, especially in tropical and semitropical climates, and in all places subject to the inroads of infectious disease.

We of the medical profession remember him as our Surgeon General during the early part of the World War. We remember his prompt recognition of the necessity of bringing into active service large numbers of physicians and surgeons from civilian life. We remember his genial and kindly nature, his high character, and his steadfast effort directed toward the organization and equipment of the Medical Corps of the Army. We remember the patriotic response. We remember him as a great sanitary officer, to whom we wish to pay a lasting tribute.

A central committee has been formed, with Admiral Braisted, retired, ex-President of the American Medical Association, as its president. The American Medical Association has appointed a committee of three to work in accord with the central committee, and through its members this appeal is made to the American medical profession.

The plan is to build at Panama an institute for the study of tropical and infectious diseases, with a hospital, laboratories, departments for research and all other facilities required in an institute of this character, erected and administered according to the most progressive, modern ideals. The Panamanian government, owing to the far-sighted, philanthropic vision of President Porras, has donated the great Santo Tomas Hospital and also the ground on which it is proposed immediately to construct the buildings as they have been described. Dr. Strong has been appointed the scientific director.

In conjunction with this work in Panama, there will be established in Tuscaloosa, Ala., the Gorgas School of Sanitation for the purpose of training country health workers, sanitary engineers and public health nurses, especially educated to deal with the problems peculiar to the Southern states.

An endowment of six and one-half million dollars will be required to enable the institute to carry on the work according to the plans which have been formed.

The Republic of Panama has demonstrated its sympathetic and practical interest in this enterprise with splendid liberality. The physicians of our country, and especially the members of the American Medical Association, surely will not disregard the memory of a former president, and will seize the opportunity to make in this respect a contribution of which they will be proud.

The campaign for funds is to be international. A large response is expected from North, Central and South America, since the nations of these countries have been the chief beneficia-

ries of the labors of General Gorgas. It is fitting that his co-workers of the American medical profession should be requested to respond generously to this appeal. It is hoped that every member of the American Medical Association will make as liberal a subscription as possible. Any sum will be gratefully received. Checks should be drawn to the order of the "Gorgas Fund" and should be mailed to the American Medical Association, 535 North Dearborn Street, Chicago.

CHARLES W. RICHARDSON, Washington, D. C.,

F. B. LUND, Boston.

G. E. DE SCHWEINITZ, Philadelphia.

DESTRUCTION OF LICE.

THE United States Naval Bulletin publishes an extract from "Sanitary Entomology" which gives approved treatments of lice on the body as follows:

A. *Crab louse*.—(1) Kerosene emulsion soap: The soap is made by boiling 1 part of soap chips in 4 parts of water and then adding 2 parts of kerosene oil, or 4 parts of gasoline. This jellies when cold, and 1 part of this soap jelly is added to 4 parts of warm water, making a good liquid soap at very small cost.

This is followed by vermin jelly:

Texas fuel oil, sp. grav. 0.86 b. p. 250 to 350° C	50 parts
Crude vaseline	20 parts
Soft soap	30 parts

The cutting or shaving of pubic or axillary hairs is to be avoided because of the discomfort caused. Powders such as N. C. I., etc., should not be used in the pubic regions.

B. *Head louse*.—Wash head with equal parts of kerosene and vinegar or 25 per cent. acetic acid for one-half hour, keeping the head covered with a towel. The vinegar separates the eggs from the hairs, while the kerosene kills them. Use a fine-toothed comb to remove the eggs and lice. Wash the head with warm water and soap containing kerosene (Nuttall).

C. *Body louse*.—(1) Bathe, using liquid kerosene soap emulsion; (2) disinfect, and disinfect clothing, possessions, etc.

In absence of facilities for the above—insecticide powder (Moore).

Cresote	1 cc.
Sulphur	½ gr.
Talc.	20 gr.

Fumigation: Entomologists prefer cyanide.

In "Investigation of the Louse Problem," by W. Moore and A. D. Hirschfelder, the authors give the following summary of the problem:

1. Lice and their eggs are destroyed by the ordinary laundering processes used in the washing of cotton and khaki goods; for wooleens slight alterations in the methods of washing are necessary.

2. Chlorpierin may be used for fumigation of garments, accomplishing the desired results in a short period of time, with a small quantity of the chemical, without the use of high temperatures.

3. The sachet method of controlling lice is ineffective or very expensive.

4. Louse powder may be used with success but, being a wasteful method of applying an insecticide, is not recommended.

5. Impregnation of the underwear is the most promising method of louse control between lousings. Active chemicals of very low volatility are necessary to prove effective for the longest period of time. Halogenated phenols, such as dibrom-metaresol, dichloro-mono-brommetaresol, and their sodium salts, dibromearvaerol, and dibrom-xylenol were found to be the most promising

COUNCIL ON PHARMACY AND CHEMISTRY.

The following articles were accepted during July:

Intra Products Company: Ven Calcium Caedylate Ampules-Ipec.

Winthrop Chemical Company: Theocin.

During August the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies:

G. W. Carnrick Co.: Corpus Luteum-G W. C. Co.

Gradwohl Laboratories: Sterile Solution of Mercury Oxyceyanide Gradwohl.

Lederle Antitoxin Laboratories: Pollen Antigens-Lederle, Solution Epinephrine-Lederle.

New York Intravenous Laboratory: Loeser's Intravenous Solution of Mercury Oxyceyanide.

Parke, Davis and Co.: Antipneumococcic Serum (Polyvalent).

Winthrop Chemical Co.: Luminal Sodium Tablets $1\frac{1}{2}$ grains.

PROVISIONAL BIRTH FIGURES: 1922

The Department of Commerce announces that provisional birth figures compiled by the Bureau of the Census for the first quarter of 1922 indicate lower birth rates than for the corresponding quarter of 1921. For the states compared, the total birth rate for the first quarter was 23.3 in 1922, against 25.3 in 1921. The highest birth rate for the quarter (29.2) is shown for North Carolina and the lowest (16.5) for the State of Washington. Higher rates will be necessary for the remaining months of the year if the 1922 rate is to equal the 1921 rate for the Birth Registration Area—24.3.

MORTALITY FIGURES

Provisional mortality figures compiled by the Bureau of the Census for the first quarter of 1922 indicate higher death rates than for the corresponding quarter of 1921. For the states compared, the death rate for the first quarter was 13.7 in 1922, against 12.6 for the first quarter of 1921. The highest mortality rate for the quarter is shown for the District of Columbia (17.6) and the lowest for Wyoming (9.6). These early figures forecast for the year 1922 a higher rate for the death registration area than the record low rate (11.7) for the year 1921.

Obituary.

THE PASSING OF A LEADER IN MEDICINE.

DR. STEPHEN SMITH, the well-known surgeon and public health officer of New York, died at Montour Falls, near Elmira, N. Y., August 26, 1922, at the great age of ninety-nine years, six months and seven days. That he would round out the century span was his conviction—a normal lease of life, as he thought, for did it not take twenty years to perfect the bony skeleton in vertebrates? Five times this period would be a proper age for the individual if he observed the rules of health laid down by Dr. Smith, namely, to work hard, not eat too much meat, drink plenty of milk and sleep many hours at night.

The son of a cavalry officer in the Revolutionary War, he was born on a farm at Skaneateles, Onondaga County, on February 19, 1823. As a boy he worked on a farm in the days when farmers got up at four o'clock in the morning and kept at their varied tasks until dark.

Before he had determined to study for a profession, he had studied Latin and Greek. He attended the Academy of Homer, where he was declared to be prepared for the sophomore class of college. Instead of completing his college course, ill-health induced him to enter upon the study of medicine with Dr. Caleb Green of Homer. Under his advice the pupil attended his first course of lectures in the old Geneva Medical College. In 1850 Dr. Smith came to New York and entered the College of Physicians and Surgeons, Columbia University, from which he graduated in 1851.

From 1854 to 1891, Dr. Smith was professor of anatomy at Bellevue Hospital Medical College, and in 1856, associate editor of the *Journal of Medicine*.

An accomplished surgeon and teacher, his "Handbook of Surgical Operations," published early in the Civil War, was widely distributed to the surgeons of the Federal Army. Later his "Operative Surgery" became a standard textbook in the medical schools of the country.

Even before the war he became interested in improving the sanitation of New York, a work which occupied his attention for a long series of years. Through publicity and the assistance of the *New York Evening Post*, he was able to draft a law creating a board of health, and get it passed. Forced to accept the position of health officer under this law, he accomplished yeoman service in cleaning the streets of their filth, establishing health ordinances, and doing away with the scourges of smallpox, typhus, cholera, and diphtheria, which had killed their thousands. Extending this salutary service, he organized and became the first president of the American Public Health Association, which spread throughout the country the propaganda for municipal cleanliness. In his ninetieth year he published a book describing the shocking health conditions in our chief American city before the sanitary era, entitled: "The City That Was."

In his old age he was appointed president of the New York Department of Charities, and instituted far-reaching reforms which did not meet the approval of Mayor Van Wyck, who removed him from office, as he wrote: "for the good of the service."

While a delegate to the Ninth International Sanitary Conference of Paris, when seventy years old, Dr. Smith cured himself of chronic dyspepsia by following the French custom of taking wine with his meals. His account of this experience led the newspapers to cite him as an advocate of the use of alcohol, and the prohibition propagandists to refer to him with scorn.

Recently Dr. Smith had finished two books: "Who Is Insane," depicting his experiences as a lunacy commissioner, and the volume already referred to, "The City That Was." Until a short time ago he had enjoyed good health and had addressed audiences on health problems, his portrait appearing in the art supplements of the Sunday newspapers within a few months.

Correspondence.

CARRYING POSTGRADUATE INSTRUCTION TO THE DOCTOR, NORTH CAROLINA'S PLAN.

Mr. Editor:

The following letter was written at my request by Dr. Frederick R. Taylor of High Point, North Carolina, with the idea that the physicians of Massachusetts would be interested to hear what has been done in another state toward stimulating better medical work.

Yours truly,

HENRY A. CHRISTIAN.

High Point, N. C., August 16, 1922.

Dear Doctor:

According to your request, I am sending you a few personal impressions of the University Extension Postgraduate Instruction in Medicine as I have seen it in North Carolina. Anything I may say is purely an individual student's view of what seems to me

an extraordinarily valuable method of postgraduate medical teaching.

The essential principle of the work is this: To make possible more widespread postgraduate medical education by sending the instructor to the practitioners, instead of leaving such education to those favored few among the doctors who can get off to distant medical centers.

The first work of the sort which was done in North Carolina was in 1916. The subject chosen was Pediatrics, the branch of medicine in which postgraduate education was most needed in our section. Two instructors were obtained, one from Harvard for eastern North Carolina, and one from Northwestern University, Chicago, for western North Carolina. I believe that this work caused a very striking reduction in infant mortality from diarrheal diseases in our section, though I have no statistics on this point. I am sure that since 1916 I have seen far fewer cases of "alimentary intoxication" and "decomposition" of Finkelstein, and of dysentery in babies, than I saw previous to that time, and those infantile diarrheal disturbances, that I have seen since then, have been of a much milder type, on the average. Dr. C. S. Grayson, of this town, who has a large pediatric practice, shares this view, and Dr. D. A. Stanton, the dean of the profession here, when asked if he thought the course in Pediatrics profitable, replied that he considered it worth \$1,000,000 to High Point and vicinity.

The war interrupted this work after 1916, and it was not resumed until this year, when the subject of Internal Medicine was selected, there being two instructors, one from Harvard and one from the University of Chicago. In our section the scheme followed is this: The instructor has a circuit of six towns, Asheboro, Greensboro, High Point, Lexington, Salisbury and Charlotte. It was planned that a class should be held each weekday in one of these towns. As nobody wanted a class on Saturday, the work is doubled up so as to have classes in two adjacent towns on Tuesdays, and no class is held on Saturday. The course lasts twelve weeks, each town thus getting twelve lectures. A set subject is presented at each lecture, but after the lecture members of the class are privileged to bring in patients of any kind for diagnosis and discussion, whether they bear on the day's subject or not.

As examples of the subjects taken up, our group was given the following lectures in 1916: Milk, digestion of milk, modern conception of "disturbances of nutrition," failure to gain, the states of dyspepsia and intoxication, decomposition, parenteral and enteric infections as factors in the causation of "disturbances of nutrition," artificial feeding of the normal infant, breast feeding, the disturbances arising in the breast-fed, acute anterior poliomyelitis, obscure causes of fever, convulsions.

This year the subjects so far have been: Lobar pneumonia, chronic lung diseases other than tuberculosis, epidemic encephalitis, endocarditis, angina pectoris and aortitis, irregularities of the heart, peptic ulcer and gastric cancer, constipation and the visceroprotosis syndrome, nephritis and diabetes.

There are a number of striking advantages in this method of having a peripatetic instructor to teach the doctors in their own communities. In the first place, the cost to the individual student is so slight as to put it within the reach of practically everyone. Both in 1916 and this year, \$30 per student has been the charge for a complete course of twelve or thirteen lectures. The only condition is that a certain minimum number of students— I think fifteen—must be guaranteed before a class will be held in a given community. Payment for the entire course is made at the beginning of the first lecture, when an organizer from the university accompanies the instructor, introduces him, and handles all financial matters with

the students. Another saving to the doctors is, of course, elimination of travelling expenses to a distant medical center and living costs while away. The greatest economy, however, results from the fact that in this system the doctor loses no time from his work. This makes it possible to reach a very large number of men who could not, and some who would not, otherwise get postgraduate instruction.

A second marked advantage of this method of teaching is that the clinical demonstrations are given on diseases and conditions existing in the physicians' own community, and the problems of their everyday work are thus elucidated. This is no small matter. A doctor in a small town may go to some great clinic and feel that the methods of examination and diagnosis in use there are impractical at home. With the method of teaching under discussion, he sees modern diagnostic procedures applied at home, and, perhaps quite as important, *the patients see them, and learn to appreciate and to demand careful, systematic examination.* This at once raises the whole standard of medical practice in a community.

The university has shown wisdom, I believe, in selecting for their teachers in extension work young, able men hailing from a considerable distance. It is seldom possible to get a man of long experience and ability for such work, and a young man of ability is far better than an older man of mediocrity. It is of some importance that he should come from a section too far away to attract many patients from the locality where he is teaching. This removes all suspicion of self-interest from his work. If a local man taught the course he would almost unavoidably engender jealousy in the minds of some others who would desire the work, or whose patients would change to the instructor for their regular physician.

Coming from a distance and having no axe to grind, the instructor can occasionally indulge in some pointed comments to the good of all concerned. For example, a mother brings in a child with chorea. Prolonged rest in bed is advised. The mother says, "But she doesn't want to stay in bed." Whereupon the instructor turns on her rather fiercely and demands, "Mother, who's the boss at your house, you or your child?" Mother doubtless doesn't like this, but she can't fire the instructor, and in the end it has a distinct tonic effect upon the morale of all concerned. In a community where all patients are private patients, such moral tonics are all too rare. The instructor may also tend to speak his mind more freely to his students when he lives too far away to expect to be called by them in consultation practice.

There are certain obvious educational advantages to the teacher in coming from a distant section. He comes in frequent contact with some diseases that are uncommon in his own locality, and thereby broadens his experience. For example, a Northern physician teaching in our section would probably have opportunities to study pellagra and hookworm disease that he could not get at home, although both these diseases are far less common here than they once were. In some parts of eastern North Carolina there are also exceptional opportunities for the study of malaria, though this disease is rapidly decreasing, too. The teacher will also inevitably come in contact with some ideas and methods that are new to him, and even if these are not always of the latest date he cannot fail to pick up an occasional point of value. The relation of teacher and student is always a reciprocal one, and there is no better way to learn than to teach.

"But there is neither East nor West, Border nor Breed nor Birth,

When two strong men stand face to face, tho' they come from the ends of the Earth."

And no two earnest, conscientious physicians can get together and work on a common problem without both deriving benefit from their contact, no matter what their differences in training, opportunities, methods or environment.

Just a few words as to the subjects in which postgraduate education of the type under consideration would seem to be especially valuable. Such work is not intended to develop specialists; it is for the purpose of keeping practising physicians in touch with the essential features of modern medical practice. The educational needs of different communities will naturally vary to a considerable degree. Obviously, physicians located in great medical centers have no need of this type of instruction; they can go to the schools for their postgraduate work at a minimum of time and expense. In our locality, instruction in Pediatrics was urgently needed at the time the course was given. Internal Medicine, dealing as it does with so wide a field, is always timely.

Therapeutics is a field in which postgraduate instruction is much needed; not so much what to give, perhaps, as what not to give, and a study of the action of drugs. Men in practice are incessantly bombarded with literature from all quarters of the earth, advertising all manner of so-called "ethical proprietaries," very many of which are neither ethical nor can they be used with propriety, but fortunate is he who can stand against the continuous summation of stimuli urging him to use the latest (?) scientific (?) discoveries (?) in the treatment of all human ills, unless he also has a balance wheel in an opportunity to obtain really scientific postgraduate therapeutic instruction.

Elementary neuropsychiatric work is another subject in which there is crying need for more knowledge among the profession as a whole, and I hope some day to see this subject brought to us. Dermatology instruction is much needed, but sufficient clinical material is hardly available in small communities. Surgery and the other specialties seem to me to be such highly specialized fields that they should be taught only in medical centers with ample facilities and clinical material, but I am not competent to discuss these fields.

Different subjects present rather marked variations in their didactic problems. In our locality, Pediatrics found a very receptive audience, as the members of the class had relatively little knowledge of infant feeding. Doubtless they would be equally receptive towards Neuropsychiatry. With Internal Medicine the problem is somewhat different. Here, at least, the more alert members of the class are in a more or less argumentative mood, rather than a purely receptive one. Everyone takes a fling at Internal Medicine, and everyone has his pet theories and practices. Informal discussion plays a relatively large part in this instruction, and has proved very helpful. No doubt Therapeutics would show like didactic problems.

In closing, let me make it clear that I am in no way degrading the usual method of going away to a great school for postgraduate medical instruction; that has been, is, and always will be, invaluable, and in a class apart by itself, for those able to avail themselves of it, but I do believe that this University Extension work is one of the most valuable things that have been done in the history of medical teaching, from the standpoint of widespread benefit to the medical profession and the public.

Very sincerely yours,

FREDERICK R. TAYLOR.

High Point, N. C.

NEW YORK AND NEW ENGLAND ASSOCIATION OF RAILWAY SURGEONS.—The 32nd annual session of this association will be held in the Colonial Room, on the third floor of the Hotel McAlpin, New York City, on Saturday, October 28th, under the presidency of Dr. Donald Guthrie of Sayre, Pennsylvania. A very interesting and attractive program is being arranged for this session. Plans are under way to make this the biggest and most successful session ever held by this association.

RECENT DEATHS.

DR. CALVIN OLIVER PRINCE, for more than thirteen years a practising physician of Plymouth, formerly the medical superintendent of the New England Sanitarium at Melrose, Mass., died at his home in Plymouth, July 28, 1922, at the age of forty-nine, from myocarditis.

The son of Charles A. Prince, he was born in Amherst, N. H., in 1872, and graduated from the American Medical Missionary College, Chicago, in 1899. He was a member of the American Medical Association, the Massachusetts Medical Society, the Plymouth County Medical Society and of the staff of the Jordan Hospital. Lately he had given special attention to obstetrics. For nearly two years he had been in failing health, the end coming from an attack of myocarditis.

He is survived by his widow, three sons and a daughter.

DR. JOSEPH HENRY CUNNINGHAM of Cambridge is reported to have died in London, England, on August 28, 1922, while on a foreign tour with his wife.

He was born in Prince Edward Island, Canada, in 1867, and had lived and practised in Cambridge for thirty years, being on the staff of the Holy Ghost Hospital for Incurables. His education was received at St. Dunstan's College, Canada, where he took an A.B. in 1888. In 1892 he was graduated in medicine at Harvard.

His wife, who was Miss Josephine Carroll of Chattertown, P. E. I., survives him, as does a brother, Henry J. Cunningham, former commissioner of public safety in Cambridge. Dr. Cunningham was a member of the American Medical Association, of the Massachusetts Medical Society, and of the International Club.

DISEASES REPORTED TO THE MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH.

WEEK ENDING AUGUST 19, 1922.

Disease.	Cases.	Disease.	Cases.
Anterior poliomyelitis	12	Pneumonia, lobar	19
Chicken-pox	10	Scarlet fever	55
Diphtheria	98	Septic sore throat	3
Dog-bite	7	Syphilis	37
Dysentery	2	Suppurative conjunctivitis	7
Encephalitis lethargica	2	Tetanus	2
Epidemic cerebrospinal meningitis	2	Trachoma	2
German measles	1	Tuberculosis, pulmonary	125
Gonorrhea	73	Tuberculosis, other forms	9
Malaria	1	Typhoid fever	13
Measles	67	Whooping-cough	110
Mumps	15	Hookworm	2
Ophthalmia neonatorum	18		

REPRINTS.

A few reprints of "The Treatment of Diabetes Mellitus" by Elliott P. Joslin (BOSTON MEDICAL AND SURGICAL JOURNAL, June 22, 1922), are available and may be procured by applying to Dr. Joslin, 81 Bay State Road, Boston.

SOCIETY MEETINGS.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue. The incomplete details and omission of names of many societies is because the information has not been furnished, although the *JOURNAL* has requested information for publication. Free publication of dates of meetings may accommodate many members of societies. Several physicians have spoken of the importance of having a schedule of meetings published so that arrangements may be made for special meetings on dates which may not conflict.

It may be possible to adopt the custom of the publication of notices of stated meetings in the *JOURNAL* and if this is generally understood, secretaries of societies could save time and expense. If general cooperation can be secured this plan can be made permanent.

DISTRICT SOCIETIES.

Barnstable District:—Hyannis.—November 3, 1922, February 2, 1923, (Annual Meeting)—May 4, 1923.

Bristol North District:—Place undecided—September 21, 1922.

Bristol North, Bristol South, Barnstable and Plymouth Districts will hold joint meetings sometime this fall.

Bristol South District:—Fall River.—November 2, 1922, May 3, 1923.

Essex North District:—Haverhill, (Semi-Annual Meeting)—Jan. 3, 1923. Y. M. C. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Essex North, Essex South, Middlesex North and Middlesex South Districts will hold joint meetings October 18. Place undecided.

Hamden District:—With Hampshire District in Holyoke. Early part of September. Regular meeting in October.

Hampshire District:—With Hamden District in Holyoke. Early part of September.

The four western districts plan to hold a joint meeting early in October.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

September, 1922. Springfield Academy of Medicine Meeting, September 12, 1922, Allen G. Rice, Secretary. New England Surgical Society. 5th Annual meeting will be held at Burlington, Vermont, on September 22 and 23, 1922, P. E. Truesdale, Fall River, Mass., Secretary.

October, 1922. Boston Tuberculosis Association. Tuberculosis Institute for Physicians will be held on October 5 and 6 at the Massachusetts General Hospital, Bernice W. Billings, Boston, Executive Secretary. New England Dermatological Society, Wednesday, October 11, 1922, at 3.30 P. M., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary. Clinical Congress of the American College of Surgeons will be held in Boston, Mass., on October 22-27, 1922, Franklin H. Martin, Chicago, Director-General. Massachusetts Association of Boards of Health, October 26, 1922, Boston, Mass., F. G. Curtis, Secretary. New York and New England Association Railway Surgeons 32nd Annual Meeting at New York City, October 28, 1922, Donald Guthrie, Sayre, Pa., Secretary.

November, 1922. Massachusetts Society of Examining Physicians, (Date and place of meeting undecided), Hilbert F. Day, Secretary. National Cancer Week, November 12 to 18.

December, 1922. New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

January, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston, Francis G. Curtis, Secretary.

February, 1923. New England Dermatological Society Meeting, February 14, 1923, at 3.30 P. M., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

March, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary.

April, 1923. New England Dermatological Society Meeting, April 11, 1923, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston, Francis G. Curtis, Secretary.

May, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), American Pediatric Society Meeting, May 31, June 1, and 2, 1923, at French Lick Springs Hotel, French Lick, Ind., H. C. Carpenter, Secretary.

June, 1923. American Medical Association, San Francisco, June 25-29, 1923, Alexander R. Cline, Chicago, Ill., Secretary.

July, 1923. Massachusetts Association of Boards of Health, July 26, Nantasket, Francis George Curtis, Secretary.

PAPERS AND DISCUSSIONS

OF THE

SECTION OF SURGERY

AT ITS MEETING AT THE HARVARD
MEDICAL SCHOOL, BOSTON,
JUNE 13, 1922.

MALIGNANCY IN THE WAR VETERANS.

By WILLIAM F. COTTING, M.D., BOSTON.

THIS series of cases is presented essentially because of the youth of the subjects, most of them at an age when one hardly expects carcinomatous disease. Whether there is any significance in the fact that these men were all ex-soldiers, therefore subjected recently to very extraordinary strain of exertion and abnormal living conditions, or whether the opportunity to present so many cases of this type within these age limits is due to the close supervision and study of illnesses occurring among war veterans, would be difficult to answer.

Parker Hill Hospital, during the period covered, has drawn a large share of the cases of serious illnesses, particularly the surgical cases, from a very large body of ex-soldiers belonging to the first, or New England District. Considering the age of the expeditionary forces, it is significant that the percentage of this very

large total of new-growths, or of the number of cases of illness, is rather strikingly large. That the outcome of these cases was so nearly always unfortunate, need give no surprise to those familiar with the courses of cancer in young individuals.

The first nine cases are true carcinoma, attested in seven by pathological report, with or without autopsy.

CASE 1. P. F., age 26.

Family History: Father and mother died of pneumonia. One brother in good health. No tuberculosis, cancer or insanity in the family.

Past History: Negative.

Present Illness: Patient enjoyed good health until the winter of 1918-1919, after which he became badly constipated, passed mucus and often a blood-streaked stool. Condition gradually grew worse, and in the fall of 1920, patient developed a pain in the rectum. Pain was relieved by bowel movement for about two hours. On account of the severity of this pain, patient went to the Boston City Hospital, where a biopsy was done, and Cancer of the Rectum diagnosed. On March 23, 1921, colostomy was performed, and these findings reported:

"Large mass found at lower end of sigmoid and upper rectum, infiltrating surrounding tissues. Mass was smooth, firmly adherent, and the size of a small orange."

After a few weeks of convalescent treatment at Sterling, Mass., pain became so severe that

patient was referred to U. S. Veterans' Hospital No. 36 for treatment. On admission, May 7, 1921, examination showed thin, poorly-nourished white man,—said to have lost twenty-five pounds during the last year. Chest was negative, except for a few sub-crepitant râles in both bases in axillae. Abdomen presented a functioning colostomy opening. Digital examination of rectum, under gas anesthesia, revealed a circular mass, about two inches inside the spincter, surrounding the lumen of the gut. It was friable and bled easily.

May 3, 1921: Patient receiving radium treatment at the Collis P. Huntington Memorial Hospital.

Several treatments were given, without apparent relief.

From November until April 25, 1922, when patient died, his cachexia increased, the pain became very severe, and an edema of the extremities developed.

Autopsy was performed, and the following findings reported:

"Heart, lungs and spleen essentially negative.

"Liver, weight 2040 grams, shows a large mass involving practically the whole of the left lobe. It is white, hard and contracted. There are visible on the superior surface of the right lobe, two other similar masses which are somewhat smaller.

"The gall-bladder appears small and shrunken, and is filled with many stones. These stones take up the full capacity of the gall-bladder, which is shrunken down about them.

"The kidneys are negative. On the right, however, there is a definite kinking of the ureter, at the brim of the pelvis. From this point up, and including kidney pelvis, the entire lumen is much dilated, being from 1½ to 2 centimeters in diameter. The ureter is filled with urine.

"The other viscera are not remarkable, except for the colostomy.

"The rectum is surrounded by a mass of extremely friable, gray, necrotic tissue, which has invaded the lumen for about 6 centimeters. This mass has also invaded the bladder and recto-vesicular tissue.

Diagnosis: carcinoma of rectum, metastatic carcinoma of liver, cholelithiasis."

CASE 2. S. C., age 27.

Family History and Past History: Negative.

Present Illness: Patient admitted to U. S. Veterans' Hospital No. 36 March 12, 1920. For the past two years patient has complained of frequent nosebleeds. This is the only complaint. On admission, the physical examination was negative, except for slight anemia and a new-growth in the left nostril. Tissue from this nostril showed the following:

"Specimen shows carcinoma, the cells of which are but little differentiated and show mitotic figures."

A few days later a second biopsy was performed by Dr. Wright of the Cancer Commission, Harvard University, and a diagnosis of carcinoma made.

On May 1, 1920, under nitrous oxide anesthesia, a radical excision of the tumor was performed. It was necessary to resect the septum and the greater part of the superior maxillary bone. Patient returned from the operating room in a surgical shock. Proctoclysis and hypodermoclysis were instituted.

May 1, 1920: Since operation patient has developed a cough, slight temperature and increase in pulse rate. Chest findings indefinite.

May 8, 1920: Examination of the chest shows slight dulness on the right, from the third rib down. There are a few crepitant râles.

May 15, 1920: General condition slightly worse than it has been for the past week. Examination of the chest shows definite signs of consolidation, which might be an abscess of the lungs or empyema. Paracentesis was not possible on account of his general condition. Patient has occasional chills and is very restless. Sputum examination positive for diplococci pneumoniae. X-ray of the chest by bedside unit shows the following:

"Large triangular area of increased density with base at the periphery, under region of right middle lobe. Findings consistent with pneumonic process."

Sputum report from the state laboratory showed one gram positive and one gram negative for staphylococci. Hospital laboratory showed sputum negative for pneumococci and positive for staphylococci.

Patient's condition steadily grew worse from hour to hour,—temperature, pulse and respiration varying, until May 27, 1920, when patient died. Autopsy was not performed.

CASE 3. S. T., age 30.

Family History: Negative.

Past History: Negative, up until present trouble.

Present Illness: While in France, November, 1918, patient reported to hospital infirmary with pain in the back, between the scapulae. This pain has been more or less constant up until three months ago, when it was referred to the right side of the chest, gradually increasing in severity. Patient was admitted to U. S. Veterans' Hospital No. 36 February 23, 1921, for observation for tuberculosis. He had lost forty pounds in the past months. Chief complaint was pain in the right axilla, accompanied by a cough and dyspnoea. Examination of the chest—negative for tuberculosis; temperature, pulse and respiration normal.

February 28, 1921: Patient cannot sleep, has marked dyspnoea, severe pain in back and side,—referred to the lower quadrant of the belly. X-ray of the chest shows:

"Lower portion of the right chest very dense, and obliterating the right costo-phrenic angle. The line of density follows the axillary border,—slight haziness above this area. No fluid level noted. There is slight displacement of the heart to the left. The shadow in the right base merges with the diaphragm."

Physical examination on this date showed signs of fluid, without any definite level, and condition thought to be a chronic pleurisy with effusion more or less localized by adhesion.

March 1, 1921: Condition unchanged. Patient is raising a large amount of sputum, which is negative for tubercle bacilli. Urinalysis negative. Examination of the abdomen by the Surgical Service on this date showed nothing remarkable. Paracentesis of the right chest performed and two grams of straw-colored fluid removed.

March 8, 1921: Chest aspirated, and 120 c. c. of fluid removed, followed by considerable relief of the dyspnoea. Sputum negative for tubercle bacilli. Blood Wassermann negative. Blood count normal. Culture of chest shows pneumococci.

Condition remained the same until the 1st of April, when the pain became centered over the gall-bladder region. This area was exquisitely tender and had slight muscle spasm on palpation. Paracentesis revealed no fluid. Respirations rapid and labored.

April 8, 1921: Condition very much improved. Respiration less labored; not so much pain. X-ray shows marked diminution of the dense area of the right chest. Patient has lost five pounds in the past week; sputum scanty and negative for tubercle bacilli. Examination of the belly at this time shows an indefinite, irregular mass in the upper right quadrant. It was thought that this might be the liver pushed down by fluid in the chest. Chest was tapped and only a small amount of blood obtained.

April 21, 1921: Considering the fact that for the past week the symptoms have pointed more to gall-bladder, and the fact that there is a demonstrable tumor mass, laparotomy was performed. The liver was found somewhat enlarged, and a large retroperitoneal mass, presumably cancer, was found. This mass was extensive, and at a position just behind the liver, at the head of the pancreas. Culture was taken from the abdominal fluid which was present in small amount, and specimen removed from tumor mass.

Patient's condition grew steadily worse, and he died on the 23rd of April, 1921. No autopsy. Examination of the tissue showed carcinoma.

CASE 4. J. N., age 34.

Family History: Negative for tuberculosis, cancer or insanity.

Past History: Operation for appendicitis when a child. Was gassed in France, July 1, 1918. Hospitalized for six months.

Present Illness: After discharge in 1919, patient was granted vocational training on account of the dyspnoea which he suffered following gassing. While in training, he had pain in the region of the stomach, and it was for this pain that he was sent to the hospital. Patient states that for the past three or four months he has noticed a yellowish tint to the skin, which has gradually increased and become more marked during the last three weeks. Patient was admitted to this hospital Jan. 5, 1922.

Examination reveals a well-developed and fairly well-nourished white male. There is a marked yellowish tint of all conjunctivae. Examination of the chest reveals marked increase of vocal fremitus in the right apex, with slight dullness over the right apex, and broncho-vesicular breathing. There are no râles present. Heart negative. Abdomen: tenderness in the midline, below the sternum. No masses felt. Lower border of liver is about a finger's breadth below the costal margin.

January 9, 1922: X-ray of the chest shows slight cloudiness in the right apex.

January 13, 1922: Bismuth series of the gastro-intestinal tract shows the following:

"Six hours after motor meal, fluoroscopic examination shows meal in lower ileum and caecum. These structures are of normal contour and position. Caecum is slightly fixed. Liquid meal was given, and revealed an orthotonic cow-horn stomach of normal contour. Pylorus somewhat fixed. Plyoric ring patent. No duodenal cap. Twenty-four hour plate shows meal in caecum, ascending and transverse colon and rectum. The above changes are indicative of moderate gastropnoia. Right upper quadrant lesion cannot be ruled out."

January 24, 1922: Patient passing normal colored stools. Urinalysis negative, except for bile. Blood Wassermann negative.

February 18, 1922: Considering the fact that this patient has had a persistent jaundice, presumably of the obstructive type, and that patient's condition has not improved, exploratory operation was deemed advisable. This was done on this date, and no evidence of stones in the gall-bladder or ducts found. There were numerous adhesions in the region of the gall-bladder, extending down to the caecum. Gall-bladder was drained, the adhesions severed, and the belly closed.

For the next two or three days patient made a good recovery, gall-bladder draining well, pulse and temperature normal.

February 21, 1922: Patient is taking small amounts of liquid at frequent intervals. He is troubled considerably with hiccups; spent a very poor night on account of this. Nitroglycerine offered temporary relief. Patient occasionally vomits a small amount of greenish-yellow fluid.

February 22, 1922: Gall-bladder draining well. Patient's jaundice increasing in the past 48 hours; hiccups has persisted without relief. Examination of the wound shows that because of hiccups a few stitches have broken loose and wound is oozing a small amount of fresh blood. Patient is running a slight temperature and pulse is up to 120. Jaundice increasing; gall-bladder draining well.

February 27, 1922: Patient being fed per rectum. Hiccups only occasional and mild in character. There is presumably a peritonitis present, and, considering the fact that we have an obstructive jaundice, question of cancer is entertained.

May 1, 1922: Patient gradually growing weaker; jaundice more intense until death.

Autopsy shows the following points of interest:

"Pleura of the right lung is everywhere adherent to the chest wall. Left lung has one or two small adhesions anteriorly, otherwise negative.

"Heart is negative.

"Lungs negative, except for hypostatic pneumonitis.

"The liver weighs 2100 grams. Superior surface is covered with areas of fibrin. On the lower margin is an indentation corresponding to a mass of clotted blood, which weighs 500 grams. Otherwise the liver is not remarkable.

"Gall-bladder is bound to the liver firmly by adhesions. At the tip there is a small area, undergoing surgical repair. The mucosa of the gall-bladder is slightly injected; bile is thin and yellowish, non-purulent. On opening the gall-bladder there is a mass measuring 2 x 1 centimeters in diameter, which surrounds the cystic duct and invades its lumen. This mass is pinkish-yellow in color and contains a few minute areas of hemorrhage, the mass compressing the duct markedly. The duct, however, is patent, as a very fine probe can be pushed through.

"Kidneys are negative.

"Spleen is negative.

"The other viscera are not remarkable.

"Histological diagnosis: Heart shows edema of connective tissue; cardiac fibers are cloudy and show occasional fatty changes. There is some sedimentation of the fibers. Blood-vessels are all dilated. Acute infection—Myocarditis.

"Lungs show areas containing giant cells of caseous necrosis. Alveolar walls contain dilated blood vessels which show a large number of polymorphonuclear leukocytes in lumen. Alveoli contain considerable serum. Hypostatic pneumonia; pulmonary tuberculosis.

"Tumor consists of epithelial cells, fairly closely packed together, with an arrangement which is slightly suggestive of alveoli. There is an abundant stroma in which there are numerous polymorphonuclear leukocytes. Many of these are acidophilic.

"Diagnosis: Alveolar cancer."

CASE 5. W. C., age 33.

Family History and Past History: Negative.

Present Illness: In January, 1920, patient began to have pain in the region of the stomach, associated with belching of gas and heart-burn. He had no vomiting. Antacids did not relieve his symptoms; eating made them worse. The bowels were constipated all this time. Just prior to admission patient began to complain of dyspnoea and dizziness. He states that his abdomen began to swell about eight weeks ago.

On admission, September 17, 1920, examination revealed a well-developed and nourished male negro, showing signs of moderate loss of weight. Eyes, ears, nose and throat negative. Glands palpable in sub-maxillary, anterior and posterior cervical and inguinal regions. These are small and discrete. Over the chest wall there are eight nodules, presumably glands, from one to three centimeters across. These are slightly tender and are not adherent to the skin, but fastened to the fascia beneath. The large one feels lobulated. Small scars are found in the axillae from incisions through which the glands are said to have been excised at the Newton Hospital in August, 1920. Lungs are negative, except for a few medium moist râles on the right. Heart negative. Abdomen distended, with definite signs of shifting dullness. Succussion sounds and fluid wave are both easily elicited. No masses made out. Extremities show considerable wasting. Reflexes normal. Paracentesis of the abdomen done, and 2900 centimeters of blood-stained fluid removed. Abdomen injected with oxygen. X-ray shows the following:

"Liver appears slightly enlarged. Shadows in the abdomen indicative of fluid; no other pathology noted."

Urinalysis shows trace of albumin, many red cells, numerous hyaline casts and a few pus cells.

Patient feels fairly well, but will not eat.

September 17, 1920: Urine shows a large amount of albumin, a few red cells and a few hyaline casts; many leukocytes. Abdominal fluid shows specific gravity, 1012; white cells, 3100 per centimeter; red cells, 7000 per centimeter. Smear shows small mononuclears, 72; polymorphonuclear leukocytes, 28; no tubercle bacilli found. Culture showed an abundant growth of B. Coli. Albumin, 10 per cent.

September 23, 1920: Abdomen is filling up fairly fast with fluid. Patient has considerable discomfort on account of the distention. He was seen by medical consultant and a diagnosis of pulmonary tuberculosis and tuberculous peritonitis was made. Abdomen was tapped and nearly 6000 centimeters of blood-tinged fluid removed. Patient very weak and uncomfortable.

September 25, 1920: Condition much worse. Examination of the ascitic fluid shows no tubercle bacilli; blood count shows 3,448,000 red

cells; 8600 white cells; hemoglobin, 75 per cent.; 97 per cent. polymorphonuclear leukocytes; 2 per cent. small mononuclears; 10 per cent. large mononuclears.

Patient died September 26, 1920.

Autopsy performed shows briefly the following:

Peritoneal cavity contains about one quart of dark, straw-colored fluid. Peritoneum throughout has a whitish, granular appearance.

The liver reaches about two inches below the edge of the ribs. It is deep purple in color and shows numerous whitish nodules on the surface.

Diaphragm reaches to the fifth space on the left, and to the fourth space on the right.

Enlarged lymph glands can be felt behind the sternum.

Both lungs are adherent to the chest wall throughout.

The greater omentum is thickened and tough, and is studded throughout with small yellow tumors, about a millimeter or two in diameter. The surfaces of the large and small intestine and peritoneum are thickly studded with thousands of these pale, yellow tumors.

Heart not remarkable.

Left lung shows small, pea-sized nodules, scattered throughout both lobes. Cut surface shows normal amount of fluid. Nodules are rather tough on section and grayish-yellow in color. None of these nodules are broken down.

The right lung is also studded with these nodules.

The apices of the lungs show no special change.

The spleen weighs 200 grams, is somewhat enlarged, and very hard and stiff. The indentations in the margins are marked. Numerous hard, pale yellow nodules, about 1-3 of a centimeter in diameter, appear on the surface. On section, the spleen is tough and thickly studded with nodules, which project in places from the surface. These are yellow in color; none broken down.

The gall-bladder contains several friable stones and considerable sand. Attached to the neck of the gall-bladder is a hard tumor, the size of a walnut. On section, it is tough and pale yellow in color.

The liver weighs 1580 grams. Its surface is pale, and studded with nodules, similar to those found in the spleen. On section, the liver is filled with these nodules.

The kidneys weigh 150 grams each. Capsule strips easily. On section, the markings do not show well. The cortex cannot be sharply differentiated from the medulla. The aorta shows a moderate degree of fibrous sclerosis. The head of the pancreas is thoroughly invaded by a new growth which is tough and almost uniformly pale yellow in color. It shows a slight tendency to lobulation in places.

Diagnosis: Carcinoma of the pancreas, with

metastases in the liver, spleen, retrosternal lymph glands, and probably in the lung.

CASE 6. M. H., age 50.

Family History: Except for the death of a sister by cancer, family history is negative.

Past History: Patient had measles and scarlet fever at sixteen; influenza in 1919.

Present Illness: While in France in 1921, patient's trouble began with digestive disturbance and constipation, thought to be due to inadequate diet. The onset was slow and symptoms indefinite,—at times constipation being the most prominent symptom. His trouble continued up until the present time. Patient was admitted to this hospital September 19, 1921, for observation. Chief complaint at this time was pain after eating, associated with considerable gas in the stomach and constipation.

Physical examination shows a thin, fairly well developed white man, with evidence of marked loss in weight. Eyes, ears and nose are negative. Lungs show some increase in tactile fremitus on the right, with a hyperresonance on the left, from the fifth rib down. There are no other signs of pathology present. Heart is negative, except for slight enlargement of the right auricle. Abdomen is slightly distended, being hyperresonant throughout the epigastric region. There are no masses felt, no areas of tenderness, and no muscle spasm. Kidneys, liver and spleen are not palpable. The knee jerks are equal and active.

September 28, 1921: X-ray of chest shows moderate hilus and bronchial thickening; an occasional calcified nodule noted, otherwise negative.

October 2, 1921: X-ray of the gastro-intestinal tract shows stomach in the median, transverse position; peristalsis slightly increased. Unnodal cap shows some irregularity, consistent in both fluoroscopic examination and in the films. Six hours shows the stomach well empty. Twenty-four hours shows considerable angulation at the hepatic flexure, which appears low. Proximal portion of the transverse colon looped, and appears tied down to the caecum. Head of the barium column being at the descending colon, denotes no obstruction. Seventy-two hour plates give no further information.

October 16, 1921: In the meantime the patient's symptoms remained essentially unchanged as they have since the onset, that is, (1) constipation, (2) two hours after every meal, has a dull, burning sensation in the right hypochondrium, always arising there and then radiating to the left side and downwards. It is not acute in any way; is accompanied by more or less intestinal flatulence. Symptoms gradually pass off after an hour or two. They are no worse after one meal than another, because patient eats so little; avoids meat and vegetables which seem to form gas. Appetite continues to be poor.

Constipation is relieved somewhat by fluid extract of cascara.

October 20, 1921: Symptoms unchanged; feels sure he has lost thirty-five pounds since the onset of the disease. History would seem consistent with pathology in the right lower quadrant. This is backed up by the x-ray finding of adhesions in this region. A barium enema and x-ray shows considerable angulation at the proximal portion of the transverse colon. Under the fluoroscope it is impossible to separate this area of kinking and the caecum.

October 29, 1921: Operation is being considered. Further questioning of the patient gives the history that last July, while at home, he passed a kidney stone. He was x-rayed, and the result was said to be positive for stones in the right kidney. Therefore it is deemed advisable to have the Urological Service study the case further. X-rays show two discrete foreign bodies in the region of the right kidney pelvis, presumably stones. Urine examination shows slightest possible trace of albumin, no sugar, and a few hyaline casts.

November 15, 1921: In spite of the fact that in this case we have definite evidence of stone in the kidney, the present symptoms are very definitely of intra-abdominal origin.

November 16, 1921: Under nitrous oxide anesthesia, an exploratory midline incision was made, and the abdomen opened. There was no evidence of gastro-intestinal obstruction. Gall-bladder was somewhat enlarged; no evidence of stones. In the region of the head of the pancreas, there was present a scirrhus mass, about the size of a fist. Another hard tumor, about the size of an almond, was found above the right kidney. Section was removed from the pancreas mass, and sent to the laboratory. Gauze drain was inserted, and the abdomen closed.

November 21, 1921: Patient's condition remained about the same until 7.45 this morning, when his color suddenly became poor, pulse rapid, and patient died at 9.05. Autopsy permission was not obtained. Laboratory findings are as follows:

"Strands of carcinomatous tissue lying in a stratum of fatty tissue. Diagnosis: Carcinoma, head of pancreas."

CASE 7. C. G., age 34.

Family History: Mother died of "womb or stomach trouble," and father of "kidney trouble."

Past History: Practically negative, up until June, 1916, when he developed digestive symptoms, appearing as nausea and dull, gnawing pain in the epigastrium. These symptoms gradually grew worse, and seemed to appear about two or three hours after meals. He occasionally vomited bile colored material; very little food in the vomitus. One morning at work, after eating an apple, patient was seized with a severe

attack of pain in the epigastrium. He felt weak, dizzy, and fell to the floor. On regaining consciousness, he vomited a large amount of "coffee-ground" material, and also some bright red blood. Patient was taken to the Peter Bent Brigham Hospital, where condition was diagnosed as "Ulcer of Stomach." Gastrojejunostomy was performed on December 7, 1916, at the above-named hospital, for obstructing carcinoma of the stomach. Patient was relieved of all symptoms, gained in weight, and seemed to be in perfect health.

In May, 1918, patient was struck in the lower chest and epigastrium by a swinging breech-block, while dismantling gun, but was not rendered unconscious. Two or three days later, while stooping down to pick up something, he felt dizzy and sick to his stomach, vomited yellow, watery material, followed by about one-half an ounce of bright red blood. Patient was treated at the company infirmary for a few days and then returned to duty. He had occasional dull pains in the lower chest and epigastrium up until June, 1918, when he began vomiting from one to two hours after meals. October 26, 1918, immediately after breakfast, was nauseated and vomited a large clot of dark brown blood, followed again by bright red blood. Operative procedures were recommended while in France, but never performed. In March, 1919, pain again reappeared, more severe than ever before. Patient felt good off and on, but had occasional gastric attacks; appetite was fair, with no loss of weight, but gradual loss of color.

In January, 1920, all symptoms of distress, nausea and vomiting, and pain in the lower left chest and lower stomach region reappeared more frequently than before, with about the same intensity. Pain became more severe in February, 1920.

Patient was admitted to the U. S. Veterans' Hospital No. 36 first on April 5, 1920. At this time he complained of cramping or drawing up of all fingers, both hands, especially little fingers; pains and tightness across the sternal region of the chest. A diagnosis of Dupuytren's contraction of fifth digit, both hands, was made, —improved by operation. Patient also vomited occasionally at this time. He was discharged on October 6, 1920.

On December 16, 1920, patient had another gastric hemorrhage, which was possibly one quart or more in quantity,—"coffee ground"—and which was again followed by blood.

Patient was re-admitted to this hospital on December 18, 1920, with complaints of weakness, dizziness, spots before eyes, nausea, gaseous eructations and the tasting of blood in mouth. The question of ulcer of the stomach was changed to carcinoma of the stomach, based on the findings at operation at the Peter Bent Brigham Hospital in 1916. Patient also showed localized areas of swellings, characteristic of angioneurotic edema. This, however, gave him

very little trouble. He was discharged on July 23, 1921, with a diagnosis of Carcinoma of Stomach,—condition much improved.

In September, 1921, symptoms of vomiting and dizziness again reappeared. On September 18th, patient coughed up a large clot of blood, solid and dark brown in color, also vomited a large amount of "coffee-ground" material.

Again re-admitted to this hospital on November 21, 1921. Complaints were practically the same as on previous re-admission. Food was said to have no relation to pain, unless the patient was hungry along with it. He has lost about seven pounds in weight; appetite is poor, but bowels regular; no marked dyspnoea on exertion.

Examination revealed the following:

General appearance: white male, well developed and well nourished. Apparently anemic. Nose: deviation of nasal septum to the right, with a basal ridge on the left and spur on the right. Partial obstruction of the nares. Moderate hypertrophy of the middle turbinate on the left. Mucous membranes normal. Abdomen: tympanitic throughout. No masses or muscle spasm; slight tenderness in the epigastrium. Intestines negative. Liver palpable at costal margin. Spleen and kidneys not palpable. Skin negative, except for a scar extending in the midline from the epigastrium down to within one inch of the umbilicus, from previous laparotomy, supposedly for carcinoma. Bones and joints: the little fingers of both hands show ankylosis of the middle joints.

March 6, 1922: X-ray of gastro-intestinal tract taken on this date reveals the following:

"Six hours after motor meal, fluoroscopic examination shows meal in lower ileum, caecum and ascending colon. These structures of normal contour and position, flexible and movable.

"Liquid meal was given and revealed a stomach of peculiar shape, vertical in position, having a club-like appearance, hypotonic in type. Meal was seen passing gradually, but no duodenal cap was discernible. Lateral view showed meal leaving the stomach through the posterior wall, as if a gastroenterostomy had been performed. The outline of the stomach is irregular, and shows numerous small mouse-eaten filling defects. These are discernible in the immediate plates where the stomach, almost empty, has an hour-glass shape. Twenty-four-hour plate shows trace of meal in caecum, slight trace in transverse and descending colon, remainder in rectum.

"Gastro-intestinal examination is very suggestive of gastric carcinoma."

April, 1922: Patient sleeps fairly well at this time, but still complains of gastric soreness and pains in the chest.

May, 1922: Patient has lost about fifteen pounds in the past two months. He still complains of occasional nausea and eructations of gas and acid fluid. Patient has a definite cachec-

tic look. Examination of the abdomen reveals a definite mass in the epigastrium.

CASE 8. W. T. W., age 48.

Family History negative.

Past History: Negative, except for measles, mumps and whooping cough when a child.

Present Illness: Trouble dates back six weeks, when patient ate some canned salmon for supper, followed three hours later by severe cramps over the entire abdomen. He had three definite attacks of cramps, which lasted about fifteen minutes each. Took two doses of castor oil, with no results until the following morning. He had no vomiting, and although he felt bad the next day, he continued his work. Patient has worked every day until about two weeks ago. Following the first attack, he complained of a dull pain and distressed feeling in the epigastrium; was tired out, and felt unable to do his work. This condition continued until two weeks ago, when he began to vomit. Vomiting was followed by a short period of relief. He has not vomited blood. About a week ago patient noticed that his abdomen was beginning to swell. This has increased considerably since. He has none of the old indigestion distress, but suffers considerably from the swollen abdomen. Patient considered himself perfectly well until the onset six weeks ago. He has lost considerable weight in this time.

Admitted to U. S. Veterans' Hospital No. 36, March 17, 1921. Examination as follows:

Well developed and nourished, but has apparently lost some weight. Skin and conjunctivi pale. Eyes, ears, nose and throat negative. Chest and lungs show a few crepitant and subcrepitant râles before and following cough, over both lower lobes, posteriorly. This is more marked on the right side. An occasional crepitant râle can be heard over the right apex. Heart is negative, except for some lateral enlargement. Abdomen distended with fluid. Fluid wave felt; signs of shifting dullness present. A mass, the size of a small grape-fruit, can be felt in the epigastrium. There is no special tenderness and no muscle spasm. Urinalysis shows slightest possible trace of albumin, and a very rare hyaline cast. Blood count shows 3,080,000 reds and 4,000 whites; hemoglobin, -65 per cent; small mononuclears -11 per cent; large mononuclears -1 per cent; neutrophils -85 per cent.

March 18, 1921: Abdomen tapped and 2,000 c.c. of straw-colored fluid removed. Blood Wassermann negative. X-ray of the stomach, following a bismuth meal, shows annular carcinoma, involving the antrum and pyloric end of stomach. X-ray of the lungs shows no evidence of metastases.

March 21, 1921: Report of fractional gastric analysis, following Ewald meal, shows no free acid, and a very low total acid. Blood is present in two specimens. Lactic-acid is present in all,

Fasting contents show many squamous epithelial cells; numerous Oppler-boas bacilli. Stomach empty in one hour and one-half. Patient's pulse is very poor, and condition considered grave. Fifteen minims of tincture of digitalis given.

March 21, 1921: Patient sleeps a good deal; no particular discomfort. Report on the ascitic fluid received, and shows a cell count of 990; differential count—large mononuclears —2 per cent.; small mononuclears —13 per cent.; neutrophils —85 per cent. Specimen negative for tubercle bacilli. Albumin —12 per cent.

April 5, 1921: Patient's condition averaged about the same as usual. Paracentesis of the abdomen was to be considered today. Patient died at 3.10 A. M.

Autopsy performed, and shows the following points of interest:

Peritoneal cavity contains six quarts of ascitic fluid.

The heart is nearly as large as two of the individual's fists. There is a large amount of epicardial fat. Heart weighs 500 grams. The right auriculoventricular valve measures 140 millimeters in circumference; the left auriculoventricular valve, 115; pulmonary valve, 85; aortic valve, 75. There is a moderate degree of fibrous sclerosis in the aortic valve, on the surface of the aortic bulb, and in the coronary arteries. There are no changes in the other valves.

The lungs are essentially negative.

The stomach shows a large mass, the size of the subject's fist, on the anterior wall of the stomach, near the pylorus, extending up onto the lesser curvature. This mass is five inches long, four inches wide and one inch thick. It protrudes into the stomach surface, and has an irregular, cauliflower appearance. It is tough and hard, fairly well circumscribed, but has no capsule. Pylorus is not invaded.

Spleen and kidneys are negative.

The liver weighs 3,050 grams. It is pale, mottled and yellowish. On the right lobe there is a large, shrunken scar. On the anterior lower margin of the left lobe there is a large, pale, hard mass. There is a similar one on the left side of the left lobe. On section, the liver is hard, and shows scattered masses of hard, pale tissue. Some of these measure two inches in diameter.

There are numerous large retroperitoneal glands in the upper part of the abdomen. Aorta shows a moderate degree of sclerosis.

Anatomical diagnosis: Carcinoma of the stomach, with metastases of the liver and retroperitoneal glands. Heart: Myocarditis, dilation, hypertrophy.

CASE 9. A. D., age 48.

Family History: Mother died of nephritis; father of "old age." No tuberculosis, cancer or insanity in the family.

Past History: Patient had typhoid fever

twelve years ago; measles and whooping cough. Otherwise he had always been healthy.

Present Illness dates back to August, 1919, when he began to have trouble with his stomach. Was nauseated and troubled with considerable gas formation. In September, 1920, patient was operated upon at the Peter Bent Brigham Hospital for gastric ulcer. On admission to that hospital, he gave a history of pain in the epigastrium for the preceding three months, coming on about an hour after eating; somewhat relieved by drinking hot water. Pain became so steady that during the last month he had very little freedom from it.

Gastric bismuth studies showed a small defect in the lesser curvature, with an irregular duodenum. There was no stasis. No masses could be felt, but there was moderate epigastric tenderness.

Operation under ether. "Stomach presented a most remarkable condition of induration posterior to the lesser curvature, half way from the pylorus to the cardia. Induration on the anterior wall extended one-third way across the stomach, and posteriorly to the great curvature. The mass was firm, slightly boggy, as though a spreading infection of the gastric wall were present. Many glands were involved, inflammatory in character, especially those of the gastrohepatic omentum. Immediate pathological examination showed what at first sight seemed to be a carcinoma, but a frozen section from two places showed nothing but ulcer. This case is considered to be on the border line of a phlegmonous gastritis. Sleeve resection was performed. Postoperative x-ray shows the stomach to be considerably reduced in size, and shows a six-hour residue considerably reduced in amount. The stomach was somewhat sluggish in peristaltic wave, as the barium was going through. The head of the barium column was in the caecum, at the end of six hours.

"Diagnosis: Floor of Gastric Ulcer."

On account of the present complaint of pain and severe constipation, patient was admitted to this hospital for treatment May 13, 1921. Examination on admission was practically negative, except for healed operative scar in the abdomen, marked tenderness on palpation throughout the epigastrium, and a palpable mass.

May 16, 1921: Considerable difficulty in getting patient's bowels to move. Enemas and castor oil given without avail. Blood Wassermann negative.

May 18, 1921: Gastric analysis shows complete absence of hydrochloric acid. Blood was positive in several tubes. X-ray of the gastrointestinal tract reveals a filling defect involving the antrum of the stomach. Pyloric portion of first part of duodenum not filled at any time. Peristalsis lost well up in the fundus. Condition decided to be inoperable.

June 6, 1921: Patient gradually getting weaker, vomiting throughout the day. Vomitus contained "coffee-ground" material.

June 11, 1921: Patient slowly sank into an unconscious state, and died at 9:30 A. M.

Autopsy shows a mass, the size of a large grape-fruit, firmly attached to the lesser curvature of the stomach, to the right, and behind the pylorus. It invades downward, across and around the duodenum and pancreas. On section, this tumor is rather hard, and shows small areas of necrosis. Near the pylorus, on the surface of the inner wall of the stomach, there is a large, mushroom-like ulcer, about one and one-half inches wide, with raised edges. This lies opposite the tumor.

Diagnosis: Carcinoma of the Stomach.

The cases which follow, are cases of the mesoblastic or endoblastic type, not in themselves remarkable, in the age of the cases affected, but included in this paper for completeness in the study of malignancy in the earlier years, and for the intrinsic interest of certain of the cases.

CASE 10. H.K.J., age 29.

Family History: Mother in good health; father died of cancer of the stomach. Two brothers and one sister dead,—causes unknown.

Past History: Patient has always enjoyed good health up until the present illness.

Present Illness: Was taken sick in February, 1920, with a bad cold. Since that time he has been a bed patient, has lost weight and feels tired most of the time. During this period, patient began to have trouble with his stomach in that he had to be careful about his diet, always felt a dull, distressed feeling in the region of his stomach; has always been constipated. He has been having night sweats ever since the onset.

Physical examination on admission, June 1, 1920, reveals a small man, considerably emaciated. Heart negative. Lungs: left apex shows bronchial breathing; a few moist and crepitant râles in the axillary space, from the third rib down. There is a small area of roughened breathing with râles over the base posterior,—at the lower margin of the lungs, about one inch and one-half from the spine. The right lung apex is slightly duller than the left. In the axillary space, at the level of the third rib, is an area about 2 x 1½ inches, which shows rough bronchial breathing, with numerous moist râles. The abdomen is tympanitic, except in the flanks. This dullness is found to shift with position. Fluid wave can be elicited. Recti muscles are rigid, and show muscle spasm. The entire abdomen is tender to pressure. On admission, the diagnosis was that of Tuberculous Peritonitis. Patient is running considerable fever. Urine is entirely negative. Blood count shows 3,900,000 reds; 70% hemoglobin; 11,400 whites. Sputum is negative for tubercle bacilli. Blood Wassermann is negative. Patient runs a temperature

from normal up to 103.4. Pulse ranges from 85 to 95.

June 7, 1920: Sputum is negative daily. X-ray of chest shows slight thickening about the hilus. There are many annular areas of increased density, constituted of dilated bronchi and bronchioles.

Conclusions: Findings consistent with chronic bronchitis, with bronchiectasis.

Patient seen by surgical consultant and operation advised after a few more days of observation.

June 11, 1920: Feces negative for blood; show occasional pus cell; no amoebae.

June 17, 1920: On the advice of both medical and surgical consultants, exploratory laparotomy was advised, probable diagnosis being tuberculosis of the peritoneum, and a question of malignancy. Under nitrous oxide ether anesthesia, the abdomen was opened through a midline incision. Many retroperitoneal glands were found, a few of which showed necrosis. Two wicks were placed in the abdomen, and the whole closed in layers.

June 20, 1920: Patient's condition seems to be improving; abdomen draining profusely through the abdominal wound.

June 23, 1920: Patient suddenly took a bad turn last evening and died at 5:00 A. M. this morning. Permission for autopsy was granted. Report follows:

"Large retroperitoneal mass found back of the attachment of the mesentery. This mass has a large necrotic cavity in it, opening into the peritoneal cavity. There are numerous, slightly enlarged mesenteric glands.

"The left lung is attached to the wall by numerous adhesions. The parietal pleura, near the upper part, shows two groups of fungus-like white masses, very hard, but not calcified,—feels like cartilage.

"The lungs are negative for tuberculosis.

"The heart is also negative.

"Stomach—About two inches below the pylorus is a hard sear, about one centimeter in diameter, on the posterior wall of the duodenum. In front of the duodenum, and around the pancreas, is a mass of tough tissue, which on section shows discrete, yellowish areas, mixed with brownish-red areas.

"Liver shows large and small lumps, scattered over the surface, varying in size from one-half centimeter to three centimeters in diameter. They are pale and project from the surface.

"The rest of the organs are practically normal."

Two specimens were sent for laboratory examination to the Hygiene Laboratory, Washington D. C., and the following report given:

"Retroperitoneal gland shows Hodgkin's Disease."

Another specimen was sent to Dr. F. B. Mallory at the Boston City Hospital. His report was briefly as follows:

"Strongly suggestive of gumma. Examination negative for tubercle bacilli. The glands were much enlarged and showed extensive necrosis, but definite cells. It is possible that the lesion was a lymphoblastoma specimen with extensive necrosis, but no definite cells. The subsequent history ought to tell, because in the latter case I should expect the patient to be dead by this time."

CASE 11. W. F. J., age 20.

Family History: Father and mother living and well. Two brothers living and well. No tuberculosis, cancer or diabetes in the family.

Past History: Negative, except for measles, diphtheria, chicken-pox and whooping cough in childhood.

Present Illness: This dates back to February, 1919, when the patient developed a mild attack of influenza, lasting ten days. This was followed by persistent pain in the back and chest. Patient has been in run-down condition ever since. He developed enlarged glands in groin and both axillae a few months after the influenza.

Patient was admitted to this hospital January 29, 1921, complaining of shortness of breath, pain, constant throughout his chest, loss of weight and poor appetite.

Examination showed a fairly well developed, but poorly nourished young man. He presents a small chain of glands, both sides of neck, above the clavicles. There are a few palpable glands in the left axilla, right lobe and both groins. The lungs show slight dullness over both apices posteriorly, with prolonged, harsh respiration; no râles or increased voice sounds. Heart is negative. Abdomen is tender throughout; no masses or spasm present. There is thinning of the right epididymis, non-tender, non-inflammatory. The hands and feet are slightly cyanotic.

February 4, 1921: X-ray of chest negative, except for occasional dense, calcified nodules in the hilus. Blood examination shows 4,900,000 reds; 3,700 whites; 70% hemoglobin; 6% small mononuclears; 35% large mononuclears; 56% neutrophils; 1% eosinophiles; 2% basophiles.

February 11, 1921: White blood count—2,800. Patient referred to the Collis P. Huntington Memorial Hospital for consultation as to the advisability of radium therapy. It was his opinion that the condition was definite Hodgkin's Disease, and arrangements were made for treatment.

February 16, 1921: In report of treatment—patient slightly improved.

For the next two months patient continued to lose weight and strength.

August 12, 1921: On account of the low number of red cells and the general appearance of marked anemia, patient was transfused, and 500 c.c. of whole blood given. Examination at this time reveals a mass, about the size of a small grape-fruit, in the left hypochondriac region, ir-

regular in outline and slightly tender to palpation.

For the next week or so condition remained practically unchanged. Blood picture has improved, but patient has had several chills.

August 27, 1921: Transfusion of 500 c.c. of whole blood.

September 3, 1921: Transfusion of 600 c.c. of whole blood.

After each transfusion patient's blood picture improved, but there was no definite improvement in the general condition. He continued to grow weaker, and died November 14, 1921.

Autopsy performed.

"There is a large retroperitoneal mass extending up to the edge of the ribs and down to the level of the anterior superior spine.

"Lungs are practically negative, except for the appearance of several glands throughout the hilus.

"Spleen is over nineteen centimeters long, ten centimeters wide and six centimeters thick. It weighs 510 grams. It is very dark in color, rather soft in consistency, and on section shows large prominent corpuscles.

"In the region of the spinal column, behind the peritoneum, is a large mass, 170 centimeters long, 130 centimeters wide and about 70 centimeters thick. It is lobulated bi-laterally with a groove down the center. The top of the mass is at the level of the seventh rib, and the lower edge at about the level of the umbilicus. The mass is firmly fixed to the posterior wall. It cannot be peeled, and must be cut away. This mass is made up of a group of very much enlarged lymph glands. It weighs 790 grams.

"Diagnosis: Hodgkin's Disease."

CASE 12. G. H., age 22.

Family History: Father's mother died of cancer of the face. Father's father had a growth of the lip removed.

Previous History: Negative, except for diphtheria, measles and mumps.

Present Illness dates back one year. Onset with pain in the lumbar region. Consulted doctor, who strapped his back. Pain was relieved for about seven months, and then began again. It was worse at night, and in October, 1920, became severe. Patient went to the M. G. H. Out-Patient Department, for treatment. There he had two casts applied. Pain remained in the lumbar region, and never radiated. In the latter part of November, his back became so stiff that he could not bend over. Condition was diagnosed as chronic arthritis, and was later thought to be tuberculosis of the spine, and treated as such. After the last cast had been applied, patient began to have pain over his hips; noticed that his feet and legs felt heavy on getting up in the morning. This gradually increased. He removed the cast, and at the same time noticed a loss of muscle power in the legs. He began to lose sensation from the waist

down. This gradually increased, until about ten days ago, when he was completely paralyzed. Two days later he lost control of the bowels. About five days before admission to this hospital, he had to be catheterized, and at the same time noticed that he had a small lump on his back, to the left of the spine, near the point of the scapula. It increased in size, and then went down some, later becoming larger than ever.

Patient was admitted to this hospital March 28, 1921, chief complaint being pain in the back, paralysis of motion and sensation from the ribs down, and incontinence of urine and feces.

Examination on admission revealed a fairly well developed and nourished man. Heart showed a loud systolic murmur heard over the entire chest, best over the base of the heart. Lungs showed slight dulness over the right apex. Flatness noted over the left base, posterior from the fourth dorsal spine down. Breath sounds are normal, except over the flat area in the left base. Here they are absent. Whispered voice also absent here. Abdominal wall looks otherwise negative. Patient presents a complete motor and sensory paralysis below the tenth dorsal nerve. All reflexes absent below this point. He has no control of sphincters. Patient presents marked tenderness from the third to the ninth dorsal spine. To the left of the spine, at the level of the sixth vertebra, is a swelling about the size of a goose egg, which is firm and quite tender. Blood Wassermann is slightly positive. Blood count shows 4,800,000 reds, 7,200 whites; 75% hemoglobin.

April 1, 1921: The swelling on the left back explored with needle. Nothing found.

April 15, 1921: X-rays of the chest and spine show as follows:

"The thoracic vertebrae appear clear-cut and distinct, apparently not diseased."

April 29, 1921: Patient vomited large quantities of dark-colored fluids. The stomach is greatly dilated, filling most of the abdomen. Several small masses can be felt in the abdomen, at times one in the epigastrium, and several lower down.

May 3, 1921: Patient slightly improved, having recovered from the dilated stomach. He is considerably weaker.

May 7, 1921: Patient's pulse became poor, was cold and cyanotic, and died at 3:15 A. M.

Autopsy:

"Lower lobe of the left lung is firmly attached with adhesions throughout. There is a small amount of fluid in the left pleural cavity.

"The heart showed a congenital stenosis of the pulmonary valve, with hypertrophy of the right ventricle.

"Left lung: the lower lobe of the left lung, on its outer surface, feels hard and not at all crepitant. The upper lobe, on section, is pale, and no fluid drips from the surface. The lower lobe on section is like liver in consistency, dark purple in color, and a small piece sinks in water. The

pleura in this region is about one-quarter of an inch thick. The lung pleura and tissue behind the left lung, are thoroughly grown together. In the midst of this mass is a large tumor, nearly three inches across. On section it is dark purple in color, rather soft and watery, and has invaded the vertebrae behind.

"The other organs are not remarkable, except for the tumor which seems to have invaded the cord, at the level of the ninth vertebra. On the dorsal aspect of the cord, the tumor runs from the top of the tenth to the bottom of the seventh dorsal spine. This is about as wide as the cord, about two and one-half inches long and one-quarter of an inch thick. This tumor is firmly adherent to the dura, but can be dissected off: the dura itself, apparently not being invaded. The tumor does not involve the cord, but on cross sections the markings of the cord are not as clear in the region of the tumor.

"Diagnosis: Round Cell Carcinoma."

No differentiation can be made between sections of the tumor removed from the dura of the spinal cord and those taken from the pleural cavity. The tumor is extremely vascular, blood vessels being in all stages of completeness. The tumor mass is made up of small, round cells, which are massed together heavily. Occasionally the cells are grouped, as to suggest an alveolar arrangement.

CASE 13. J. J. C., age 29.

Family History negative for tuberculosis, cancer or insanity.

Past History essentially negative.

Present Illness: While in service at Camp Dix, N. J., August, 1918, patient states that he was struck in the right shoulder by the kick of a rifle. Three days later he developed a swelling at the base of the neck, on the right side. He had no pain, but the tumor gradually enlarged and interfered with his wearing of a collar. In May, 1921, patient became alarmed at the continuous growth of the tumor and went to the Massachusetts General Hospital, where he had the neck glands excised. Eight weeks ago patient noticed a lump in the right axilla, and was admitted to this hospital September 6, 1921, for this condition. Abstract from the Massachusetts General Hospital records show the following: "May 3rd—operation and biopsy. Gland, the size of a marble, excised from the left side of neck. Microscopic examination shows a neoplasm composed of eight typical cells of the lymphocyte series. There is a marked fibrosis with eosinophilia. Masses of giant cells with multiple nuclei are conspicuous.

Diagnosis: Malignant Lymphoma.

May 11 operation.—excision of glands of neck. Tumor mass, the size of a baseball, was removed. Examination of this tissue revealed the same histological picture as on May 3rd."

On admission to this hospital, patient had no complaint, except the presence of the tumor.

Examination disclosed a moveable, firm tumor mass, about three centimeters in diameter. The rest of the examination was negative.

September 11, 1921: Blood examination shows 4,872,000 reds; 7,800 whites; 85% hemoglobin; 9% large mononuclears; 14% small mononuclears; 10% transitionals; 1% eosinophiles; 75% neutrophils. Urine examination—negative. Blood Wassermann—negative.

September 16, 1921: Radical excision of all glands of the axilla was performed. Wound healed by first intention. Microscopic examination of the tissue removed shows invasion of the lymph node by many small cells which have a very dark stained nucleus. These cells replace the normal lymph structures in many places. Growth is so rapid that many cells are necrotic.

Diagnosis: Malignant Lymphoma.

Patient made an uneventful recovery and was discharged from the hospital on October 25, 1921. There was no evidence of metastases at this time.

CASE 14. P. DeF., age 27.

Family and Past Histories are negative.

Present Illness: In June, 1920 patient's brother states that the patient appeared rather sleepy most of the time. He would often fall asleep when not busy at work, but seemed in good health at all other times. During the latter part of August, 1920, the right eye began to close up. About the middle of September the left arm became so weak that articles would slip out of his hand. About two weeks later patient noticed that the left leg also became weak. This condition gradually increased. At present he is unable to stand or walk, cannot sit up, speech is blurred and has difficulty in swallowing.

Examination on admission to this hospital, December 24, 1920, reveals the following:

Eyes: Ptosis of right upper lid. Eyeballs practically fixed; very little lateral movement possible. Pupils of medium size; react easily to light and distance. Ears negative. Hearing considered normal. Mouth: Tongue protrudes to the left on extension; the lips to the right, when patient shows teeth. Throat: Soft palate moves a little; otherwise negative. Face: Brows wrinkle well,—better on the right than on the left. Left side more flaccid than right. Chest: Heart normal. Lungs: negative, except for a few rales in the right axillary space. Abdomen negative. Reflexes: Babinski and Oppenheim negative. Slight ankle-clonus present. Suggestion of Kernig. Hyperactive knee reflexes. Left leg and arm spastic; no muscular movements possible. O. D. practically obliterated; veins distended, some exudate. O. S. much obliterated; can be seen partly on the temple side; veins distended, some exudate. Blood pressure: Systolic 122; diastolic 80.

January 5, 1921: Examination by the ophthalmologist reveals choked disc and complete oph-

thalmoplegia, both eyes. A tentative diagnosis of brain tumor, involving the brain stem, was made. Spinal fluid on this date is negative for the Wassermann reaction; blood count practically normal.

From the time of admission until the time of death on January 12, 1921, patient was in practically a semi-conscious condition.

Autopsy was performed, with findings in brief as follows:

There is nothing remarkable about the inner surface of the skull or about the surface of the dura. The brain weighs 1580 grams. On section, the brain reveals tumor on the right optic thalamus. The most ventral section appears merely slightly pinkish. Gradually the color becomes darker red and the consistency softer, and finally a short distance ventral to the pulvinar, the tissue is completely broken down into a dark grayish mass. This broken-down mass is surrounded by a tough gray wall, about one millimeter thick. The ventral two thirds of this abnormal structure is not sharply separated from the normal tissue of the thalamus, but gradually merges into it. The whole interior of the thalamus is involved, leaving a shell of apparently unaffected tissue on the outside, about one-half centimeter in thickness. Microscopic section reveals numerous glia cells with varying amounts of fibrous tissues, very vascular.

Diagnosis: Glioma of the Optic Thalamus.

TUBERCULOSIS OF THE BREAST, WITH THE REPORT OF TWO CASES.

By P. H. LEAVITT, M.D., BROCKTON, MASS.

ONE of the rarest forms of tuberculosis with which we have come in contact is that of infection of the mammary gland. About 200 cases have been reported, and these by a large number of operators. Undoubtedly more cases have occurred and remain either unreported or not recognized.

It was first reported about 1829 by Sir Astley Cooper, who described the gross appearance of the lesions and referred to it as "scrofulous swelling of the bosom," concluding his paper with the following—"they produce no dangerous effects and do not degenerate to malignancy. They do not require operation and indeed it would be impossible to remove them."

Lancereux in 1860 was the first to make a diagnosis from the examination of the histological structure of the part removed. Dubar in 1881 was the first to describe the microscopical appearance of the pathology. He described the two types which we see today and named them nodular or discrete, and confluent.

Durante and McCarthy² of the Mayo Clinic reported in 1916 an incidence of .51% over 11 years, in relation to other pathological conditions of the breast. Baer and Reis³ in April, 1921, reporting a large series of breast infections, found no involvement by the tubercle

FIG. 1. Case 1. Low Power. Light area shows caseation in glandular tissue. Darkened area shows normal gland.

bacillus. Cheever¹ in 1921 reported four cases in a total of 228 breast cases at the Peter Bent Brigham Hospital, since 1913, an incidence of 1.7%. Deaver and McFarland² report an incidence of less than 1%. Scott³ of London in 1905 found the occurrence 1.3%.

The mode of infection is subject to dispute. Gatewood⁴ believes that the infection is secondary to a retrograde lymphatic involvement from the axilla or from a primary focus in the lungs *via* Grossman's path and Rotter's lymph nodes, and advances as proof the fact that so far a case of tuberculous breast has not come to autopsy with tuberculosis confined to the breast. Of course it is true that practically every death that comes to autopsy shows evidence of tuberculosis either in lungs or abdominal cavity, so the above proof is not necessarily correct, though the assumption of that origin is reasonable.

The cases reported are as a rule in apparently healthy condition, though one of our cases was in a woman of tired, emaciated appearance. Trauma does not seem to bear a definite relation to the disease. Age is variable, though very few cases are reported after 45, none below 20. The sex incidence is predominantly female.

In involvement of other superficial glands by tuberculosis, entrance by way of, first—blood, second—lymph stream, third—by direct extension, is admitted. There are four ways in which the invasion of the breast might occur. The disease may enter the breast in any of the above ways, or it may enter through a cracked nipple, though I believe this last is the most unlikely. As in other glands, the source of invasion may vary and each case should be judged by the general picture and of course the local findings.

The general appearance of the nodular or

FIG. 2. Case 1. Medium Power. Upper right: normal gland; beneath: the lymphatolytic infiltration and two gland cells.

discrete type is that of a small lump in the breast. Halsted and LeComt found the lesion in the upper outer quadrant. The rest of the literature rarely mentions any special portion of the gland attacked. When seen early the gland is movable, the skin over it soon presents a pig skin like appearance and later redness and fluctuation may appear. As these signs appear the lesion becomes more intractable. The nipple may be retracted early or late. Glands in the axilla are about equally present or absent in the early stages. The growth of the lump is slow and painless, and as it increases the involved area may break down, then pain, soreness and fluctuation may appear. Then, too, the involvement of the axillary glands is more marked, ranging from 70-80% of cases. The involvement of the axillary glands made early observers positive that the disease was always primary in the axilla. They probably missed the disease in the

breast entirely until it became larger. It would obviously be noticed earlier in the axilla.

The differential diagnosis is of course, first, from carcinoma. More often than not it cannot be made except at operation. Several breasts have been removed and axillae dissected because of uncertainty even at that time. It is common to find in both cases, retraction of the nipple and painlessness. Carcinoma is, however, usually faster growing; but this point alone is of course not enough for a diagnosis.

Adenofibromata are slow growing and painless and when they have undergone cystic degeneration, the result resembles the changes which take place often in tuberculosis of the breast. In differentiating, however, the tubercular nodules are not so freely movable, because of the fibrous tissue which surrounds them. Then, too, involvement of the axillary glands is common with tuberculosis of the breast, but never with

FIG. 1. Case 1. High Power. Dark area shows glandular tissue with lympholytic infiltration; two cent. (11/16) to right of center.

adenofibromata. Simple pyogenic infection is more rapid and with a more definite history of a lactating breast or trauma.

Sarcomata are more rapidly growing than the nodular type. Actinomycosis, gumma of the breast, echinococcus cyst, sporotrichosis, are remote possibilities and can practically be ruled out by a careful history.

The general appearance of the confluent type is more readily recognized. The breast appears very large and seems to be completely involved, although not symmetrical. The growth is more rapid and there is more tenderness. In these cases too there is practically always a history of pre-existing tuberculosis in the lungs, pleura or neighboring structure of the chest wall; this being a very important aid in diagnosis.

The treatment in the discrete or nodular type is to remove the nodules if limited to one focus,

If more than one, it is safer to remove the breast. In the confluent type an amputation of the breast and dissection of the axilla is the best treatment.

Of course if in any case there is an incurable primary condition, then operative measures of any sort are not indicated.

There is no record of treatment by the x-ray, but, with the excellent results being obtained by the roentgenologist there is every reason to believe that all the stages of tuberculosis of the breast can be helped.

1. No. 3069 N. Female, Married, Age 39. Entered the Goddard Hospital office clinic, complaining of a lump in the right breast about 5 months. No increase in size, not tender. Youngest child 2 years of age, never any real trouble with breasts while nursing.

Physical examination: A rather thin, undernourished woman. No glandular enlargement, except local. Heart normal. Nothing abnormal noticed in lungs. Locally there is a hard, smooth-feeling lump, about size of walnut, under the nipple of right breast. The nipple is retracted, but there is no discharge. This lump is not freely movable, and no glands can be felt in the axilla. A diagnosis of cancer of the breast was made, and operation was advised. At operation (by Dr. P. H. Leavitt) the breast was removed and the lump sectioned. It appeared very suspicious so the axilla was explored and several small glands were removed at this dissection. The wound healed by first intention and the patient made an excellent recovery.

Dr. F. B. Mallory reported tuberculosis of the breast.

Six months later—patient writes that she is feeling fine. Able to work without getting unusually tired. Appetite good. Request for x-ray (free) refused on the ground of being too busy.

2. No. 3233 and No. 3381. Female. Married. Age 24. Entered the Goddard Hospital office clinic, complaining of a lump in the right breast, 2 years' duration. Has a child 3 years old, but remembers no trouble with her breast while nursing.

Physical examination: A healthy-appearing woman. No glandular enlargement other than local. Heart normal. Lungs, nothing abnormal found. Local, a good-sized tumor freely movable, 2 x 3 inches in diameter, nodular, axilla negative. Other breast negative.

Operation (by Dr. S. W. Goddard) showed an abscess cavity in the mid breast containing 1½ ounces of yellow non-odoriferous pus. The cavity was well defined, and the tumor disappeared. Culture showed a weak growth of staphylococci. The wound never quite healed but the patient did not appear again until 3 months later, at which time the breast presented a tumor similar to the first and numerous small discharging sinuses very typical of tuberculosis.

Operation (by Dr. S. W. Goddard) this time showed a tuberculosis of the breast. The latter was completely removed. There were no palpable glands in the axilla and a dissection of the latter was not done.

The x-ray of her chest by Dr. F. G. Wheatley was as follows: "There is a slight amount of peribronchial infiltration at the right apex, consistent with tuberculosis. The area involved is limited. The shadows are rather dense, indicating, probably, a long-standing lesion which may be quiescent."

The pathological report by Dr. F. B. Mallory was tuberculosis of the breast. The patient made an excellent postoperative recovery, the wound healing by first intention, and has had no trouble there since.

SUMMARY.

1. One of the rarest forms of tuberculosis.
2. Source of infection variable.
3. Diagnosis often difficult between carcinoma and tuberculosis.
4. Operation gives excellent results—type of operation depending on type of infection.

DISCUSSION OF DR. LEAVITT'S PAPER.

DR. F. B. MALLORY, Boston: The following are some statistics from the laboratory of the Boston City Hospital, which may be interesting. During the last 25 years we have had 2,297 breasts for examination. The analysis shows 956 cases of carcinoma, included in which are 26 of the colloid type, and 11 of the epithelioid type. Ordinary adenomas numbered 358, chronic mastitis 674, abscesses 27, tuberculosis, including the two cases which Dr. Leavitt mentioned, 14; all other lesions 238, among which there were two cases of echinococcus cyst and one of actinomycosis. The percentage of the cases which were tubercular was 0.6. Our record is just a little lower than Dr. Leavitt's. Both of Dr. Leavitt's cases are fairly chronic lesions with a good deal of fibrous tissue production. From one of them no tissue was available for bacteriologic examination. In the other one, although I stained sections very carefully I was unable to demonstrate any tubercle bacilli although the lesion was perfectly typical, and there was no question about the diagnosis.

Tuberculosis is sometimes associated with tumors of the breast, and carcinoma is occasionally complicated with the lesion just as in other parts of the body. Recently we had a case of adenoma in a breast which had lactated within six months. At the edge of the adenoma were several miliary and small conglomerate tubercles, some of which were invading the tumor.

The three main ways in which the breast becomes infected are, as Dr. Leavitt has mentioned, first, by direct extensions from lesions in the lung. In actinomycosis of the lungs the disease is well known as prone to invade the surrounding bones such as the vertebrae and the ribs, and to extend into the soft tissue beneath the skin. This is very rare with tuberculosis. The second way is by the lymphatics from the axillary lymph nodes. The third method is through blood infection. This seems to be the most common way, and this case I referred to as involving an adenoma would seem to be of that type, as there was no other sign of tuberculosis in the breast.

DR. R. B. GREENOUGH, Boston: The figures I have been able to gather confirm those given by Dr. Leavitt and Dr. Mallory, in regard to the frequency of this disease. In the last fifty years there have been twenty-five cases in the surgical service of the Massachusetts General Hospital, and in the last few years we have had about one a year. Not all of these, however, can be regarded as tuberculosis of the mammary gland, but must be considered as cases of tuberculosis in the region of the breast, as in cases of tuberculous osteomyelitis of the rib. Many of the cases I have seen have shown involvement of the axillary lymph nodes prior to the recognition of the disease in the breast, and I have therefore believed that infection through the lymphatics was more frequent than has been suggested by Dr. Mallory.

I have seen one case in which direct infection of

the breast by use of a handkerchief to wipe the nipple in a patient with pulmonary tuberculosis, appeared to be the starting-point of a tuberculous infection of that region. As a rule tuberculosis of the breast presents definitely a picture of an inflammatory lesion with discharging sinuses. An early case of the nodular type, however, may easily be mistaken for carcinoma, and the co-existence of carcinoma of the breast and tuberculosis in other regions occurs often enough to make the diagnosis very difficult. Other inflammatory diseases of the breast, especially the so-called "Mastitis Obliterans," or suppurative inflammation of the ducts, following a low-grade infection after lactation, may produce a condition which is clinically, and even under the microscope, readily confused with tuberculosis.

DR. LEAVITT: In regard to the feeling that the infection comes from the axilla, *via* lymphatics, don't you think it is possible that the patients would notice a lump in the axilla before they would notice one in the breast? Might it not have been in the breast for quite a long time before arm movements would be such that it would be noticed? This has been advanced by several as more in favor of a blood-stream infection.

ETIOLOGY OF STERILITY IN THE FEMALE, FROM AN ANALYSIS OF 500 CASE RECORDS.

By DONALD MACOMBER, M.D., BOSTON.

WE believe that an inquiry into the etiology of sterile matings is necessary to correct certain misapprehensions which seem to be very generally current. A survey of the standard text books on gynecology shows that the whole subject is still chaotic. In the first place, I think few physicians realize that about one out of every ten marriages fails to produce living, healthy offspring, and hence must be classed as sterile. Again, few realize the number of essentially male sterilities. Our own experience has convinced us that fully 50% of all sterile matings are the result of trouble on the male side. These facts are surprising, but no more so than those which come to light on a critical survey of a large number of cases where the trouble is on the other side. The text books, besides largely neglecting the subject of male sterility, tend to classify all female sterilities from the point of view of disease alone. It is true that most books recognize the fact that faulty development may play a part, and that general condition is a factor, but these considerations are minimized and the stress is laid upon the diseased conditions supposed to be causative. Furthermore, no one, as far as we are aware, has tabulated the frequency of the various conditions as they appear in a large series of cases.

The records from which these figures have been taken comprise a series of somewhat more than five hundred cases. Many of the records are incomplete and many are of cases of male sterility. After subtracting those records unavailable for our purpose there are left three hundred and thirty-seven cases. While this series is of course not large enough to warrant any rigid deduction it is, I think, sufficient to outline in a broad way the distribution of causes of sterility as seen in the human female. Many of these cases have more than one condition pres-

ent which might be considered as having a bearing. In such cases an attempt has been made, for purposes of classification, to pick out that particular cause which seemed of the most importance; but with even the greatest attention to simplification, a list of such causes included more than fourteen items.

Before proceeding to a detailed analysis of the various causes of sterility a few words are necessary about what we may call the "mechanism of sterility." Normally, the semen after ejaculation remains in the vagina as a definite pool into which the cervix projects. There is probably also a certain amount of suction as, however soon after coitus patients are examined, spermatozoa are found in the cervical canal. During coitus there is an outpouring of the cervical secretion which helps to neutralize the acidity of the vagina, and offers an easy path for the spermatozoa in their progress into the fundus. There is probably also an increase in the secretion in the uterine cavity which serves the same purpose. Normally, many spermatozoa reach this cavity and it is probable that a good many eventually succeed in passing into the tubes where the ovum is met. There is, I believe, one case on record where living spermatozoa were found in the tubes some two weeks after coitus. We have found spermatozoa living in the cervical and uterine secretions six days after coitus with their vitality apparently unimpaired.

Now with this brief resumé in mind let us see at what point our so-called "mechanism of sterility" becomes operative. In the first place, an excessive and over-acid vaginal secretion may, in the absence of suction by the cervix, rapidly kill all spermatozoa coming into contact with it; but while this may often be of great importance as a secondary factor, we believe that the factor of primary importance is the condition of the cervical secretion. Here we are confronted with two factors either one of which may be of the greatest importance. The first is a mechanical alteration of the secretion which we have spoken of as inspissation. Instead of having the consistency of white of egg the secretion becomes thick, tenacious, and clotted with leucocytes. Such a secretion impedes the progress of the spermatozoa and eventually all become entangled in theropy mucus. It is caused by anything that interferes with free drainage from the external os. By far the most frequent of these conditions is the under-developed, anteflexed cervix, with small or even pinhole opening. The second factor is infection. A typical infected cervical secretion is made up of mucus and is usually associated with a certain amount of erosion of the cervix. In such a secretion the spermatozoa are not only entangled, but are actually killed by its poisonous nature. Following along the course which must be traversed by the entering spermatozoa we come next to the uterine cavity. Here it is not usual to find secretions particularly altered

except as they may drain down from infected tubes, in which case they will have a lethal action similar to infected secretions in the cervix. There may be, however, alterations in the uterine mucosa due to subinvolution or other causes unknown, leading to hypertrophy and eventually interfering with the normal nidation of the developing embryo. In the tubes there may be various inflammatory changes varying from a thickening of the mucosa to absolute closure; or there may be inflammatory changes arising outside the pelvic organs themselves which by means of a pelvic peritonitis seal over the fimbriated opening from outside. Such a condition most commonly follows an acute appendicitis.

Hitherto we have dealt with causes and conditions interfering with, or preventing, the normal progress of the spermatozoa. It must be borne in mind, however, that the production of ova is equally important to the development of an embryo. There are two common conditions which interfere with the normal functioning of the ovary. The first is seen in its end-results as the so-called retention cyst ovary. Such an ovary, instead of containing one large Graafian follicle with its maturing ovum, and only a few much smaller follicles not yet at the stage of rapid enlargement, contains numerous small, thin-walled cysts with no demonstrable remains of ova. There is usually a thickening of the tunica albuginea. Whatever the cause of this condition it is certain that in its end-result it represents a non-functioning ovary.

The second condition interfering with normal functioning is the undue persistence of a corpus luteum. Normally, unless pregnancy has occurred, the corpus luteum should be retrograding by the time of the succeeding ovulation, and it is probable that it is the function of the corpus luteum to control the growth and development of the Graafian follicle. It is easy to see, if this theory is correct, that the persistence of a corpus luteum might prevent ovulation. It is to be remembered that ovulation and menstruation are two separate and distinct functions and that either may occur without the other, hence the regular occurrence of normal menstruation is no proof that ovulation is taking place. There are often no symptoms to call attention to either of these conditions in the ovary, and it is only on careful examination under an anæsthetic that the enlargement of such ovaries becomes apparent.

Having now outlined our view of the "mechanism of sterility" a word should be added on congestion. The pelvic organs of the female normally become congested with a consequent outpouring of their secretions at the time just preceding the catamenia and during coitus, but nothing which tends to make congestion excessive may have a very deleterious effect. In an already congested organ the blood-vessels are crowded; there is an excessive cervical se-

cretion; the uterus is large and heavy, and the ovaries are distinctly enlarged and tender to the touch. The persistence of this condition may interfere with the cervical secretion because of the liability to infection; it may interfere with nidation, or it may interfere with ovulation. Congestion may be caused by excessive coitus, or equally by sexual deprivation, or by anything, such as retroversion, fibroids or adhesions, which interferes with the normal venous circulation.

To summarize this conception of the "mechanism of sterility" we may say that we have certain organs taking part in a complex physiological process and that when anything interferes with this process the whole mechanism may be thrown out of balance. It is the classification of the various disorders which may affect this process that we are attempting in this paper.

Table 1.

PATHOLOGIC CLASSIFICATION OF FEMALE STERILITY

Closed tubes	19%
Tubercular tubes	4%
Endocervicitis	5%
Endometritis	2%
Retroversion	11%
Fibroids and miscellaneous	8%
Simple congestion	4%
Anteflexion	19%
Double uterus, etc.	1%
Infantile uterus	4%
Anteflexion and ovaries	8%
Retroversion and ovaries	3%
Ovaries alone	8%
Age, diet, menopause	4%
	100%

This table shows the frequency of the various pathologic lesions met as the principal diagnoses in 337 cases of female sterility.

Let us then examine the actual statistics of these three hundred and thirty-odd cases as given in Table 1. At first sight the most striking thing about this table is its complexity. It is difficult to see any simple relationship between its various items. A reference to the physiology enables us, however, to bring a little order out of this chaotic material; and further study, having in mind the useful conception previously elaborated of a "mechanism of sterility," enables us to still further simplify. This process of simplification is indicated in Table 2, and if carried on to its logical conclusion gives us Table 3.

It does not seem profitable to consider the separate items given in Table 1, in any great detail, and I shall not attempt to do so. There are, however, a number of very practical lessons which may be derived from this study, and these it seems worth while to indicate very briefly.

The striking thing about the inflammatory group is that there are only two regions in the genital tract of the female where inflammations

Table 2.

COMBINED CLASSIFICATION

Inflammatory group (closed tubes, tubercular tubes, endocervicitis, endometritis),	50%
Congestive group (displacements, e.g. retroversion; new growths, e.g. fibroids; lacerated cervix, etc.; and simple congestion),	23%
Developmental group—poor drainage (antelexion, double uterus, infantile uterus),	24%
Ovarian group (simple ovarian, and ovarian associated with antelexion or retroversion; age, diet, premature menopause),	23%
	100%

This table shows the transition between the pathology and the functional classifications of the causes of female sterility.

Table 3.

FUNCTIONAL CLASSIFICATION OF FEMALE STERILITY

Inflammatory	50%
Congestive	23%
Developmental	24%
Ovarian	23%
	100%

This table shows the various causes of sterility regrouped on a functional basis and reduced to the lowest possible terms.

are apt to cause sterility. These are the cervix and the tubes. The text books attribute most of these inflammations to gonorrhoea, and in the class of cases seen in the hospital clinics this is probably true. Curtis* of Chicago has reported a series of 300 cases of salpingitis from his hospital clinic. Gonorrhoea appeared as a cause in 70% of these cases, pyogenic organisms in 15%, and tuberculosis in 5%. Many of his cases were complicated by the presence of the colon bacillus. In the sterility clinic at the Massachusetts General Hospital a similar high percentage of gonorrhoeal cases has been found. In our group of private patients gonorrhoea plays a very small part, and most cases seem to be due to infection with some other organism. The explanation of this difference between hospital and private patients seems to lie in the undoubted fact that patients of the latter class are less subject to infection from neglected gonorrhoea in the male.

Pyogenic organisms are not normally present in the vaginal flora, at least in an active state, but they must often be introduced in coitus. Anything tending to lower the resistance might be enough to allow them to multiply. The wonder really is that such chance infections of the tubes are not more frequent than they are. Appendicitis is undoubtedly responsible for many cases of pelvic peritonitis, often involving the tubes. Old, unrecognized tuberculosis of the tubes was found in 12 of our cases; in other words, 1 out of every 6 cases of closed tubes was tubercular. This may be exceptional, but it is certain that tubercular salpingitis is a much more frequent cause of sterility than has been previously supposed.

The congestion group is, as its name implies, a collection of more or less unrelated lesions as far as the actual pathology is concerned, but which all have this in common,—that they produce sterility if accompanied by congestion, and not otherwise. Retroversion in itself, unless adherent, is harmless and it is only when the symptoms of congestion, namely, backache, bearing down sensations, and leucorrhoea, are present that it plays a part in the causation of sterility. Similarly, fibroids, however dangerous they may be to the pregnancy, do not as a rule interfere with conception unless of large size, or so situated as to materially interfere with the uterine circulation. The third item under the congestion group I have designated as simple congestion. By this term I mean the congestion which arises from long-continued sexual excess, deprivation or irregularities of habit. While this condition appears alone in only 4% of our cases it must be understood that it was a factor in a very large number of cases classified under other headings. It must also be recognized that when the organs are in a chronic state of congestion they are much more susceptible to infections both of the cervix and of the tubes; furthermore, we have come to believe very strongly that chronic congestion has an effect on the ovaries which may ultimately inhibit ovulation.

The developmental group consists chiefly of cases where there is a failure either in part or in whole of that development which normally takes place at the time of puberty. This failure of development is usually classed as infantilism, hypoplasia, or infantile uterus where it involves the whole organ; but where the cervix is chiefly involved it has been customary to describe the resulting antelexion as if it were a malposition, failing to recognize that it is in reality a condition intermediate between the infantile uterus, where cervix and body both remain underdeveloped, and the normal uterus where both have attained their full size and position. Before puberty the anterior vaginal wall is short and the small cervix points in the axis of the vagina; where development occurs only in the body of the uterus this short vaginal wall, with its underdeveloped cervix, persists, and there results the so-called antelexion of the uterus or cervix. It is probable that the dysmenorrhoea and sterility which are almost certain to follow in extreme types of this condition are not so much the result of the mechanical flexion of the canal as of the failure to develop normal unscars and glandular tissues. There is, however, a mechanical effect from the poor drainage of secretions through the pinhole so characteristic of these cases. The method by which this may produce sterility has already been elaborated.

The last group is, like the second, made up of somewhat heterogeneous items, but which all have this in common,—that the ovaries are involved. As was explained under the "mechanism

of sterility," the two common lesions of the ovary are the presence of numerous small retention cysts or the persistence of corpora lutea. There are a few cases of true cysts, but these are decidedly rare among the patients we are here considering. Taken together these lesions make up nearly 20% of all cases. Finally, we have included in this group a small number of cases showing still another type of ovary. This ovary is small and firm and on section contains more cicatricial tissue and less true ovarian tissue than normal. Such an ovary is occasionally due to lack of development, but more often represents early senile changes.

During the foregoing discussion an attempt has been made to reduce everything to its simplest terms. While such a procedure makes for ease in dealing with this subject, and helps to bring out general principles which apply throughout, there is always present the danger of overdoing it. No case is as simple as it might appear to be if placed under the simple classification shown in Table 3. In every case the secretions are of the greatest importance, and equally important is the normal functioning of the ovaries. Congestion or infection may have to be reckoned with.

In conclusion, let me reiterate the following points—in the first place, a given sterile mating may be either male or female in origin and the chances are about fifty per cent. either way. Second, where the case is one of female sterility the chances are about even that the cause will be pathological on the one hand, or developmental or functional on the other. About one-quarter of our cases had closed tubes, or some other inflammatory lesion. In one-quarter the cause of sterility was congestion from one source or another. Another quarter was essentially developmental and in the last quarter the salient feature was failure of ovulation. Finally, let me emphasize again that in dealing with sterility we are concerned primarily with disturbances in function and that mere treatment of pathologic lesions, however important that may be, will seldom by itself be successful in relieving the sterility.

DISCUSSION OF DR. MACOMBER'S PAPER.

DR. EDWARD REYNOLDS, Boston: I think the method that Dr. Macomber has taken in classifying these cases is the only one that is available for clear presentation, but it is very important to emphasize what he said, and—which needs ever more emphasis—that in practice the cases do not classify so simply. It is the rarest thing in the world to see any case which belongs in only one of these classifications. There are almost always complexities and more than one condition present. It is also very important in every case to emphasize the degree of fertility on both sides, since slight degrees of fertility on one side, multiplied as they are by slight degrees on the other side, often amount to long continued, if not permanent, sterility without treatment, although this condition is very amenable to treatment. In general the main characteristic of sterility is the complexity of the subject and the fact that the balance which determines sterility is an extremely fine, delicate functional balance requiring

much more careful analysis than the ordinary examinations which are given to the grosser lesions which determine health or disease.

A very important point is the mechanism of fertility or sterility, the disturbances of fertility to which Dr. Macomber calls attention. There are two characteristic and frequent errors which we see in many of the cases which are referred to us, most of which have been through the mill more or less already. First, we see many sterile women who have been operated on, or subjected to long treatment, for some anatomically gross lesion, such as one looks for in a gynecologist's office, but in which the treatment, operative or not, has been directed only to the evident lesion without investigating in what way that lesion has disturbed the mechanism of fertility and without treating the disturbances of fertility which are present; for that reason the sterility has not been relieved and the patient therefore turns up in our office. Many such women require a second operation for conditions which could perfectly well have been relieved during the course of the first if it had been preceded by an exact diagnosis. For instance, a woman goes to a first-rate man who is not interested in sterility. He finds a retroversion and says, "We will hang it up!"—he does a first-class suspension operation and gets a first-rate and permanent anatomical result. He very likely relieves a backache, but he is not in the habit of investigating the minor alterations of secretions which kill the spermatozoa and which are usually dependent on bad cervical drainage, or of paying attention to the minor disturbances of the ovaries which result in an absence of successful ovulation, and does nothing about such conditions during his operation. His operation does not relieve the sterility. We find one or both of these conditions present and perhaps must repeat the operation in order to produce fertility. This is only one of many such conditions.

The second ordinary failure is in the case of a couple who have been told that they are perfectly well and that there is nothing the matter with them, but who have nevertheless continued sterile, when a disturbance in the mechanism of fertility is perfectly evident on full examination and is often promptly curable. In the long run one seldom gains credit by assuring a sterile couple that they are not sterile.

To use an illustration: there is not much sense in walking up to a wood lot and firing a rifle into it in the hope of getting a squirrel. You won't get the squirrel and you may do damage. If you want to make a success you must first see your squirrel and aim at him. As the result of long experience this seems to me the most essential thing to say in any discussion on sterility.

DR. MACOMBER, (closing): Dr. Reynolds has not left very much more for me to say on the question of female sterility. I do want to emphasize, as he has also, that every case has a functional element even if there is gross pathology at the bottom of it. If you correct the pathology only, you don't necessarily get a successful result unless you see that the organs are functioning properly. The cervical secretion and the ovaries are the two important points on this question of functioning. You can get a very good idea of how the cervix is functioning by examining these patients after coitus and seeing what happens to the spermatozoa. The question of how the ovaries are functioning is more difficult to analyze. Ovulation and menstruation are not necessarily connected, although they often are. A certain hint of ovarian functioning can be obtained from menstrual history, and the examination of a patient under an anæsthetic will tell you whether there is an enlargement of either ovary; but when you come right down to it there is only one way of telling what is wrong with ovaries that are enlarged, and that is by looking at them. If you have an enlargement of the ovary with history of sterility, with everything else normal, you can by excision come down to the ovaries and recommend

operation on those and then, at the actual time of operation, correct what is found.

That is the most unsatisfactory part of the examination for sterility, and often has to be left in doubt.

It is possible that the use of some of the glandular extracts may help out in the future, but so far it is only fair to say that the field is so uncertain and is so beset with various pitfalls that it is unwise to make any assumption in that regard.

FRacture OF THE LOWER END OF THE RADIUS ASSOCIATED WITH FRACTURE OR DISLOCATION OF THE LOWER END OF THE ULNA.

By JOHN HOMANS, M.D., BOSTON,

AND

JUDSON ARTHUR SMITH, M.D.,

[From the Surgical Service of the Peter Bent Brigham Hospital, Boston.]

Read by Title.

THE fracture or fracture complex to which we wish to call attention may be thought of as a fracture of both bones of the forearm at their lower ends from one to two inches above their articular surfaces. But since the difficulty in treatment is due to the behavior of the radius, and since much the same difficulty with the radial fracture may be encountered whether the ulna is completely broken, bent, suffers an epiphyseal separation or is dislocated at its lower end, it would seem more appropriate to describe the condition as one of radial fracture with a complicating injury to the ulna.

Six patients treated upon the surgical service of the Peter Bent Brigham Hospital form the basis of these notes. In age they range from seven to thirty-one, all but one being under seventeen. The injuries with one exception cannot be described other than as falls upon the hand, but the falls were usually of some violence. The youngest, and the only girl in the series, described a fall upon the flexed hand.

One patient, the oldest, had been treated for four months before coming to the hospital, but the bones had not united solidly though fibrous union in poor position had occurred. Another had first suffered a greenstick fracture of both bones, but a second fall three weeks later had brought about a more complete fracture. Three attempts at reduction had failed before he entered the hospital. A third had been unsuccessfully reduced and had made no progress under a week of overhead traction upon the hand in bed. A fourth was subjected to traction in a similar way without effect. In a fifth, two attempts at reduction under gas were made before the patient was referred for operation. And only in one (complete fracture of both bones) was reposition without an open operation possible.

CASE 1. J. C., No. 7585, male, age 31. Four months before admission he fell upon his right hand (manner of fall not described). The frac-

FIG. 1.—Case 1. Fracture of both bones. Note backward angulation of radius and backward dislocation of the lower end of ulna.

FIG. 2.—Case 1. Anteroposterior view. Note the low level of the ulnar styloid as compared with the radius, indicating that interarticular fibrocartilage has been severed. Note also the presence of callus between the ulnar fragments and absence of callus about the radial fracture.

ture was splinted by his physician for five weeks. At the end of four months there was fibrous union in poor position.

In Fig. 1, note especially the bending of the radius backward at the point of fracture and the posterior dislocation of the head of the ulna.

In Fig. 2, note the low level of the ulnar styloid as compared to the radial (indicating that the interarticular fibrocartilage and the other radio-ulnar attachments have been sev-

ered) and the drawing of the lower fragment of ulna toward the radius (pull of pronator quadratus). At operation, the ends of the fragments of both bones were refreshed, placed in apposition as well as possible and a plaster cast applied to hold them in the corrected position.

FIG. 3. Case 1. Postoperative. Anteroposterior view. Note that the articular surfaces of the radius and ulna are now in correct relation. The angulation of the lower ulnar fragments toward the radius has not, however, been corrected.

Fig. 3 represents the ensuing condition. In this plate, note the corrected relation of the radial and ulnar styloids and the failure to correct the outward pull on the lower ulnar fragment. A lateral plate taken at the same time shows that the posterior dislocation of the ulna has apparently been corrected.

FIG. 4. Case 1. Postoperative. Anteroposterior view. The position of ulna with respect to radius is now normal.

Subsequent to operation a recurrence of the radial deformity and of the ulnar dislocation took place. A plate taken six weeks after operative reduction when union was still fibrous resembles exactly Fig. 1. From this time until union became firm, elastic pressure was maintained to correct the angulation and a statement appears on the record three months later that the bones were in good alignment and solidly united. Since then the patient has not been seen, but relatives report that he is dissatisfied with the condition of his wrist.

This case illustrates the effect upon the radial fracture of both ulnar fracture and dislocation, as well as a tendency of the fractured radius to non-union.

FIG. 5. Case 2. Lateral view. Note the anterior position of the lower radial fragments and the posterior dislocation of the ulnar shaft. The head of the ulna can be seen faintly through the lower radial fragment in its normal forward position.

FIG. 6. Case 2. Postoperative. Note the replacement of the radial fragments. The position of the head of the ulna and of its shaft seems reasonably good.

FIG. 7. Case 2. Lateral view. Note the backward displacement of the ulnar shaft. The displaced head lies considerably in front and can barely be seen through the lower radial fragments.

FIG. 8. Case 2. End-result. Dislocation of the ulnar shaft has been corrected, the shaft and head are in normal relation, and the radius has healed in good alignment.

CASE 2, D. H., No. 10021, male, age 16. Five weeks before admission he fell upon his left hand (manner of fall not described) sustaining what was at first thought to be and was treated as a Colles' fracture. Three weeks later he fell again, causing a re-fracture. Several attempts at reduction under an anesthetic then failed.

Fig. 4 illustrates the condition at this time. Note the over-riding of the radial fragments. The upper fragment is drawn toward the ulna. A separation of the ulnar epiphysis without an actual fracture of the shaft has taken place.

In Fig. 5, the lower radial fragment, contrary to the position of deformity in a Colles' fracture, is anterior. The ulna shaft is dislocated backward and is separated from the epiphysis, which can faintly be seen well in front.

At operation, the ends of the radial fragments were refreshed and so beveled that they locked together. In putting on the plaster cast the ulna could not be returned to its normal position and remained posterior.

Fig. 6 shows the operative correction of the radial deformity. In this anteroposterior view the ulnar epiphysis seems in fair relation to its shaft.

In Fig. 7, the posterior dislocation of the ulna is shown uncorrected. The epiphysis is, moreover, far in front.

The result, as shown in Fig. 8, two and a half years later, is functionally perfect. The ulna feels short and unusually movable. Inversion of the hand is very slightly increased, making up for an equal diminution in eversion.

This case illustrates the effect upon the radial fracture of separation of the ulnar epiphysis.

FIG. 9. Case 2. Lateral view. Before reduction. The direction of the deformity corresponds to that of Colles' fracture. The lower fragments of both ulna and radius are in natural relation to each other.

CASE 3, A. M., No. 14903, male, age 14. He fell upon his left hand (manner of fall not stated).

Fig. 9 shows the fracture before reduction.

Fig. 10 shows the result of reduction. Note that the ulnar fragments are apparently replaced in perfect alignment, but that the fragments of the radius, though hardly overlapping, are not in apposition.

Fig. 11, taken the same day as Fig. 10, shows that both bones are in anteroposterior alignment and that the lower fragment of the ulna is in normal relation to the radius. A week of traction by suspension in bed failed to improve the position of the fragments. At operation the

FIG. 10. Case 3. Lateral view. After preliminary reduction. The ulnar fragments are in good alignment and the radial fragments are not.

FIG. 11. Case 3. After preliminary reduction. Anteroposterior view. Taken same date as Fig. 10.

radial fragments were placed in apposition. Fig. 12 shows the condition after operative reduction. Healing was prompt and the result, as shown in Fig. 13, was anatomically and functionally perfect.

In contrast to the two previous cases, this one shows that the deformity of the radius does not tend to recur after reduction when the lower ulnar fragment is in normal relation to the radius (triangular ligament intact. No ulnar dislocation, etc.).

CASE 1. H. J. DeS., No. 13352, male, age 12. The patient fell from a moving automobile (manner of injury to arm unknown), injuring the left arm.

An attempt at reduction under gas and ten days of strong suspension traction in bed failed to improve the relation of the fragments.

FIG. 12. Case 3. Lateral view, postoperative. Note the corrected position of the radial fragments.

FIG. 13. Case 3. End-result. The bones have healed without deformity.

Fig. 14 shows the fracture before operation in lateral view. The lower fragments of both radius and ulna are anterior. There is considerable over-riding. Note that there *appears* to be no evidence of dislocation of the lower end of the ulna.

Fig. 15 confirms the findings of Fig. 14, but shows in addition that a chip has been detached from the articular surface of the radius.

At operation the radial fragments were replaced, but no attempt was made to bring the fragments of the ulna into perfect apposition. The arm and hand were placed in a plaster cast.

Fig. 16, lateral view, shows the operative correction of the radial deformity. The ulnar fragments appear barely in contact.

FIG. 14. Case 4. Lateral view. Before operation, but after prolonged traction. Note that the fracture shows the reverse of the Colles' deformity.

FIG. 16. Case 4. Postoperative. Radial fragments have been placed in position. The displacement of the ulnar fragments is uncorrected.

FIG. 15. Case 4. Anteroposterior view. To compare with Fig. 14.

FIG. 17. Case 4. Anteroposterior view. Taken same date as Fig. 16. Note the much higher level of the lower end of the ulna as compared with the radius, showing that the heads of the two bones are not in their normal relation.

Fig. 17 gives the clew to the real difficulty in this case which had not before been apparent. The lower articular surface of the ulna is not in normal relation to that of the radius but is much higher, showing that there is in fact a dislocation of the lower end of the ulna. The effects of this dislocation, doubtless a result of rupture of the interarticular fibrocartilage, subsequently appear.

Fig. 18, a plate taken over a month later, shows that bending of the radius at the point of fracture has recurred and now the *backward* dislocation of the lower end of the ulna is apparent.

The bones finally united after correction of the deformity and a year and a half later the result, as shown in Fig. 19, apparently is perfect.

This case illustrates not only delayed union of the radius, but, what is more important, the tendency of the radius to bend when the lower attachment of the ulna is insecure. The condition is similar to that shown in Cases 1 and 2 and should be contrasted with Case 3. For though Case 3 suffered a fracture apparently similar to Case 4, there was no dislocation of the ulna from the radius in the former and no tendency of the radius to bend after reduction. The two following cases further illustrate this point.

CASE 5. D. H., No. 8801, female, age 7. The patient fell upon the flexed left hand. Reduction of the fractured radius could not be effected under an anesthetic.

FIG. 18. Case 4. Lateral view one month later. Union of the ulna has occurred, but there is posterior displacement of the head. The backward deformity of the radius has recurred.

FIG. 19. Case 4. End-result, showing correction of the deformity as a result of treatment.

After the first attempt at reduction the position of the radial fragments was found to be poor. There was no over-riding, but the upper fragment remained anterior to the lower and the two were barely in contact. There was a subperiosteal fracture of the ulna without deformity. Open operation was required to restore the alignment of the radius.

The late result, three years later, is equally perfect in every way and again emphasizes the fact that there is no tendency to recurrence of the radial deformity when the lower end of the ulna is secure.

CASE 6. P. E., No. 8821, male, age 12. The patient fell from a trapeze upon the right arm

and hand, but the exact manner of injury to the arm is not known.

The fracture was reduced at once under gas—the only instance in this series in which this was accomplished.

Subsequent radiograms showed that the radial fragments were in good approximation and alignment. The ulnar fragments were barely, but probably definitely in contact.

The bones healed without delay and without any tendency to angulation, giving a perfect late result. It seems probable that here the fractured ends actually locked in contact and promptly united.

Examination of standard works on fractures fails to show that this injury has been given particular attention. Stimson states that in fracture of the radius, "at or below the middle of the bone the tendency of the biceps is to draw the lower end of the upper fragment forward and inward and that of the pronator quadratus and supinator longus is to draw the upper end of the lower fragment toward the ulna. . . . *Over-riding has been observed only when dislocation of the lower end of the ulna was associated with the fracture.*" He speaks of the use of prolonged traction to replace the radial fragments when the lower end of the ulna is dislocated, but says nothing of the tendency to displacement or angulation once the fracture is immobilized by splints or plaster.

Cotton alludes to greenstick fracture of both bones slightly higher than the Colles' line. He considers that it is a definite type in small children. It may look like a Colles' fracture, though the ulna head is not altered in relation to the styloid process of the radius. He advises against ever completely breaking such a greenstick fracture on account of the difficulty in treating the loose fracture of both bones.

There is some question whether the fracture described in these notes can be considered an entity. Its exact manner of production is not known, though several of the falls have been of considerable violence. The radius is so broken as to be left with the lower fragment anterior in nearly all cases. Therefore the mechanism must usually differ from that of the Colles'. The deformity is a little higher but many often appear much like that of the reversed Colles' (Smith's).

The initial difficulty in reduction is undoubtedly due to several factors. First, the loosening of the radio-ulnar articulation destroys the fulcrum upon which forced inversion of the hand pries loose and draws down the lower radial fragment. Second, even when this articulation is intact, the lower fragment offers a much longer arm for leverage than is the case in a Colles' fracture. Third, the pull of the pronator quadratus, which draws together the lower two inches of the radius and ulna, offers a most effective resistance against any such leverage

as can be made. And finally, straight traction which might be expected to effect reduction can be applied only to the hand and not directly to the lower fragment of the radius.

It is also conceivable that interposed muscle (pronator quadratus or supinator longus) prevents reduction, but this has never been demonstrated in the operations of this series.

The ultimate and postoperative difficulty in holding the fractured radius is undoubtedly due to the instability of the lower fragment of the ulna; not the fracture of the ulna at the level of the break in the radius, but the tearing off of the ulna from the radius at the articular surface—a rupture, in fact, of the strong interarticular fibrocartilage, the chief ligament uniting these bones. For a consideration of the six fractures here recorded shows clearly that though open operation is nearly always necessary to replace the radial fragments, *it is only in instances where the lower attachment of the ulna and radius is severed that secondary displacement and deformity occur.*

We may summarize our conclusions upon the nature and treatment of this fracture under the following heads:

1. The mechanism by which fracture is produced cannot be accurately described, but is in general a fall upon the hand; possibly a blow upon the wrist.
2. It occurs in young people.
3. The radius is fractured one to two inches above the articular surface. The ulna may be broken at the same level, but whether or not it is broken, the lower end of the ulna may be dislocated (backward).
4. The reduction of the radial fragments is made difficult by any one of a number of factors, but is almost impossible by bloodless methods when the lower end of the ulna is dislocated.
5. Open operative reduction is indicated after failure of one attempt at closed reduction.
6. After reduction, the loss of the splinting effect of the ulna due to dislocation of its lower end causes the radius to angulate even in well applied restraint.
7. After reduction, if the radio-ulnar articulation is intact, there is little or no tendency to deformity, even though the ulna is fractured on a level with the radius.
8. Open operative reduction is simple, and no suturing, wiring or plating is necessary, but the position must in all cases be most carefully watched and maintained.
9. There is a tendency to delayed union of the radius.

THE HERITAGE AND THE RECKONING OF THE SURGEON.

By MICHAEL F. FALLOX, M.D., WORCESTER, MASS.

THE consideration of the heritage of the surgeon could, perhaps, be held nowhere more appropriately than in this historic city of Boston,

for the medical profession here has always championed the highest medical standards, and has achieved the highest professional attainments.

The names of many of the physicians and surgeons of this city are writ large in the history of medicine and surgery. Even in my day were such men as Reginald Fitz, whose research work gave to us among other things the right knowledge of appendicitis and pancreatitis; John Collins Warren, who added lustre to the fame of illustrious ancestors; David Cheever, unsurpassed as surgeon, writer, and teacher; Henry P. Bowditch, said to be, in his day, the leader of American physiologists; Thomas Dwight, renowned as an anatomist; Maurice Richardson, as lovable as he was brilliant; the fearless John Homans, the skillful Porter; the genial Fred Shattuck, whose correct diagnosis never failed to elicit the wonder and admiration of his fond students. When to these illustrious names are added those of Oliver Wendell Holmes, the Jacksons, and Bigelow—we, in this neighborhood, may well regard with pride the noble heritage that has been given to us; and then, too, to Boston is due the crowning achievement and the epoch-making discovery—the giving of ether anaesthesia; the priceless gift to suffering humanity through the instrumentality of William T. G. Morton and John Collins Warren, the elder.

The study of the lives of these men shows us that their purpose was not to get all they could out of life for themselves, but to try to make the lives of others happier.

In comparison with present-day surgery, both in the principles and in the practice of surgery, the surgery of former times was extremely limited. Sir Astley Cooper said, "While it is the province of the physician to attend to internal diseases, it is the duty of the surgeon to attend to those that are external."

Practical surgery, even up to the last quarter of the nineteenth century, was mostly given to the relief of fractures, amputations, stones in the bladder, strangulated hernias and some imperative affections, mostly external.

Hence, it is not surprising that, in former days, even the most renowned surgeons had but few operations to their credit. For example, in the "Life of John Collins Warren, M.D.," at the end of volume two is appended a list of the larger surgical operations performed by him between the years of 1821 and 1851. These were performed mostly in the Massachusetts General Hospital. There were, in all, two hundred forty-three of what he calls, "the larger surgical operations" during these years, and these included amputations, bone-operations, external tumors, lithotomies and a few hernias.²

Dr. Samuel D. Gross, as late as 1864, only three years previous to Lister's famous announcement on antiseptics, in his book on surgery disposes of diseases of the gall-bladder in less than two pages. He does not even mention gall-stones as a disease.

Although their operations were few, we can imagine with what consternation the surgeon in former days anticipated an operation.

Dr. Gross said, "It has been asserted by an eminent authority, Professor Simpson, that a patient who is about to undergo a severe operation incurs as much danger as a soldier engaged in the most fierce and bloody battle. This is a strong declaration, but I believe it to be fully borne out by facts; nevertheless, it must be received with some degree of allowance."²³

As evidence of the dangers a patient faced in an operation, consider a series of herniotomies recorded by Dr. Gross.²⁴ In all, there were six hundred twenty-two cases of herniotomy operated.

Of these, there were three hundred twenty-six recoveries and two hundred ninety-six deaths, and the principal causes of death after herniotomy were shock, hemorrhage, peritonitis, erysipelas and pyemia.

Pathetic was the remark of Dr. Gross, even as late as 1864, when he says, "During an epidemic of erysipelas in Kentucky in 1845, 1846 and 1847, the slightest abrasion of the skin, the leech bite and the application of the blister were often followed by an obstinate, and sometimes even a fatal attack of the disease, and the consequence was that I was compelled, for many months, to decline the use of the knife nearly altogether."²⁵ We can readily see why surgery was not popular in those days.

Dr. John Morgan, founder of the medical department of the University of Pennsylvania, after a long time spent in study abroad, wrote from London to Dr. Cullen in 1764, "I am now preparing for America to see whether, after fourteen years of devotion to medicine, I can get my living without turning apothecary, or practitioner of surgery."²⁶

A professor of surgery might teach the principles of surgery, but he would not demean himself to operate.

The famous Von Haller (1708-1777), a professor of surgery, never performed an operation, and "Billroth commenting on this arrangement says that Albrecht Von Haller, in Berne, should, for many years, have lectured on surgery without ever having touched a single human creature with the knife, is for us in these days, hard to comprehend."²⁷

Even John Hunter's brother William tried to dissuade him from becoming a surgeon.

And yet, without the indefatigable labors of such men as John Hunter and Samuel D. Gross and John Collins Warren surgery could not have reached the high plane of the present day.

The results of the labors of John Hunter, for example, in clinical research, in physiological and pathological experiments, form no small part of the foundation of present-day surgery. Step by step, even from very ancient times, improvements leading to discoveries have marked the progress of surgery.

The ligature was known even to Celsus, but it could not be properly applied until the discovery of the circulation of the blood by Harvey, and in the development of the ligature, we owe much to an American—Phillip Syng Physick, since it was he who first advised the use of animal ligature in tying arteries, and he made these ligatures from fine strands of buck-skin.²⁸

Perhaps no factor responsible for the success of modern surgery was so spontaneous in its origin, and so quickly adopted, as was that of the anaesthetic ether.

Sir James Paget thus sums up the claims of the various applicants for the discovery of ether. "While Long waited and Wells turned back, and Jackson was thinking, and those to whom they had talked were neither acting nor thinking, Morton, the practical man, went to work and worked resolutely. He gave ether successfully in severe surgical operations; he loudly proclaimed his deeds, and he compelled mankind to hear him."²⁹

The three things more than others that have made modern surgery possible are control of hemorrhage, of pain and of infection; and, for the knowledge of infection, that is the cause of most diseases, we are indebted to Pasteur, "the most perfect man who has ever entered the kingdom of science." . . . "Before him, Egyptian darkness; with his advent a light that brightens more and more as the years give us ever fuller knowledge." . . . "To no one man has it ever been given to accomplish work of such great importance for the well-being of humanity."³⁰

Pasteur's investigations, begun with the fermentation of beer and wines, culminated in the discovery that each infectious disease is produced by development within the organism of a special microbe. Pasteur gave to us, for the first time in the history of the world, the knowledge of infection, and from this discovery more than from anything else, modern surgery has arisen.

At the time of Pasteur's announcement of his discovery of the causes of infection, Lister, who was in Glasgow, recognized the importance of the innovation that was to transform surgery.

It is difficult to realize that the humane Lister met with opposition for years in his attempt to introduce the principles of Pasteur into surgery, but, finally, the simple and sane measures of surgical cleanliness obtained, and in the decennium between 1880 and 1890, operations were done that were never before attempted. Above all, a worthy champion of the principles of Pasteur was found in Billroth, the master among master surgeons, and surgery received an impetus from Billroth in the last quarter of the nineteenth century that it had never known before. Pain, hemorrhage and infection were now under control by the surgeon, and Billroth, by his experiments upon animals, and his pathological and surgical research labors upon the human being, extended the field of surgery. Among his many notable achievements, he did the first

successful resection of the stomach, and he established many innovations in gastro-intestinal surgery that could never previously have been attempted.

What a debt we owe to the generations of unselfish men who labored often in spite of the greatest difficulties, and whose labors have finally culminated in the wonderful status of present-day surgery! And how these men did labor! No man ever worked harder than John Hunter (1728-1793). He arose about four o'clock in the morning and seldom went to bed before midnight. "Come early to me, tomorrow morning, young gentleman," he said to a medical student who had been introduced to him, "and I will put you in the way of things. Come early in the morning as soon as four if you can." The young man came at four o'clock in the morning and found Hunter dissecting a beetle.

John Hunter's income in his last years amounted to over six thousand pounds annually—a large sum in those days, and yet he died a poor man. He turned his income back into professional activities. We, today, have profited immeasurably from the results of his tireless industry.

An indefatigable worker, also, was John Collins Warren (1778-1856), the elder. He was never robust, yet he was a tireless worker. He was an early riser, and frequently labored with his books, and with his writing, until two in the morning after a hard day's labor.

And Billroth (1829-1894) worked continually for months at a time from sixteen to eighteen hours a day.

Pasteur's favorite phrase was, "Let us work!" And in a letter to a member of his family he said, "When one is accustomed to work, it is impossible to do without it. Besides, everything in this world depends on that. Armed with science one can rise above all one's fellows."⁸

What should be the reckoning of the surgeon in return for the noble heritage given him through the unselfish labors of his predecessors? In the first place, he should develop to the upmost in his preparation and in his practice the old Hippocratic standards of learning, of integrity, of humanity, and of probity.

How may he best accomplish this in his preparation for surgery? Dr. John B. Roberts, in his Presidential Address at the meeting of the American Surgical Association, June 14, 1921, answered this question admirably, and he said, in part:

"A conviction has been brought to me, by these studies, that a maximum of success up to the limit of an individual's native capacity may be best obtained by certain educational equipments acquired prior to the entrance into the undergraduate medical school and after release from the now usual hospital internship.

A real surgeon should have knowledge of logic, psychology, ethics and, at least, a familiarity with the fundamental processes of rather

advanced mathematics and of chemistry and physics. Otherwise, how can he be expected to accurately use his reason to understand and interpret the mysteries of biochemistry, physiology and the physical processes of life?

Similarly, he needs, particularly in a surgical career, a working knowledge of general mechanics, and should have some training of his hands and fingers by which his cerebral centres will be stimulated to specific reactions.

In addition to an acquaintance with Latin, he should know some Greek. Those tongues lie at the basis of medical nomenclature."⁹

Is such a preparation for the study of surgery superfluous? Let Dr. Samuel D. Gross who has been called the Father of American Surgery, answer from his own experience. When he (Dr. Gross) had studied medicine for a while, he said:

"I, at length, gave up in despair. I found that my Latin was inadequate, and that I could not understand the technicalities of medicine without some knowledge of Greek. *This was the turning point in my life.* I had made a great discovery—the knowledge of my ignorance, and with it came a solemn determination to remedy it." He consulted his preceptor, Dr. Swift, who told him "to get an education first, and then study medicine."¹⁰

John Hunter refused to get an education first, but he regretted it in after life, and the absence of an education is evidenced in his writings by errors of style and literary composition which greatly disfigure and obscure his writings.

The preferment which may come to a surgeon in uniting education with his professional studies may be seen in a consideration of some of the most prominent surgeon-generals of the Revolutionary War. Drs. Shippen, Rush, Jones, McKnight, Cutter, Morgan had both academic and medical degrees. Dr. Burnett had only an academic degree, and Dr. Turner, one of the best of them all, had neither.¹¹

The acknowledged dean of American educators in this country, Dr. William Welch, said, "There is a very unsatisfactory demand for collegiate training in this country. It is unfortunate that such a situation should exist." And again, he says, "Right practice requires abundant knowledge, nowhere more so than in medical practice, and the all-sufficient justification of the position held by the various sciences in the preliminary and the professional education of the physician is that they furnish knowledge and discipline of mind needed in the preparation for his future work. The social position of the medical man and his influence in the community depend, to a considerable extent, upon his preliminary education and general culture.

For this reason, as well as for his intellectual pleasure in his profession, and as a sound foundation for his future studies, a student should enter the medical school with a liberal education

which should include training in the sciences fundamental to medicine."¹²

And Dr. Osler, who had unusual experience in the training of medical students, said, "No one can have watched the successive groups of young men pass through the special schools without profoundly regretting the hap-hazard, fragmentary character of their preliminary education."¹³

Already the influence of such men as Drs. Welch and Osler, on proper preliminary training, appears in the requirements for the Class A medical schools for, since 1918, such medical schools require that two preliminary years of college work be taken in approved colleges of arts and sciences, thus recognizing that the cultural atmosphere in such colleges is preferable to a strictly premedical scientific course.

The premedical course, in addition to the humanities and appropriate sciences, should also include a training in right ethics.

The value of proper ethical conduct to a physician is well summed up in an opinion of Chief Justice Rugg of the Supreme Court of Massachusetts, in the recent case of a physician found guilty of gross misconduct by the Board of Registration in Medicine:

"Soundness of moral fibre to insure the proper use of medical learning is as essential to the public health as medical learning itself. Mere intellectual power and scientific achievement, without uprightness of character, may be more harmful than ignorance."¹⁴

Fortunately, for the future of medicine and surgery, the study of the humanities is coming into its own in the preliminary curriculum. If the study of the humanities were neglected, we perhaps would look in vain in the future for such doctors as Oliver Wendell Holmes, William H. Welch and Osler.

Will the combined cultural and scientific preparation unduly prolong the time of entrance into professional life? The average age of graduates from Class A medical schools in this country is now twenty-seven years. Any further lengthening of the medical curriculum may present a serious sociological problem, and more especially in retarding the marriage age; and, again, in dulling the initiative by a late entrance into professional life. Some years ago, I heard Dr. Osler discuss this problem, and his proposed solution then is the present-day solution. We cannot shorten the premedical or medical course, but we could endeavor to shorten and change the course in the lower grade schools.

Dr. Osler said, "It does seem too bad that we cannot have a student in his eighteenth year sufficiently grounded in the humanities and in the sciences preliminary to medicine; but this is a problem upon which a Milton or a Locke could discuss with profit."¹⁵

It is wholly practical for a boy to begin his study of the classics and foreign languages, together with pre-scientific studies, at the age of ten, and if the parents were to direct the early

education of their son, it would be possible for a young man to have a proper preliminary cultural and scientific training, and also, his medical training, and graduate from medical college at the age of twenty-four.

I lay stress upon what I believe to be the proper basic preparation of a surgeon since, in so doing, I believe that in no other way can a surgeon better fulfill his duty to his patient and to his profession.

Another duty of the surgeon in upholding his heritage and to advance the interests of his profession is to unite with other surgeons to protect the sacred trust vested in him.

Sir Harold Styles said, "It may safely be asserted that, in no walk of life, in no other profession, is the life of a subject so much at the mercy of his fellow-man as when he places himself in the hands of a surgeon. It is right and proper, therefore, that the profession should see to it that such a sacred trust should be placed in the hands of men who have shown that they are morally as well as intellectually and technically capable of fulfilling the trust."¹⁶

The control of hemorrhage, and of pain and knowledge of the source of infection have given to some who may not be surgeons a facility in operating that, at times, may lead to disastrous results; hence, surgeons should endeavor to authoritatively limit operative surgery to those who have had adequate training.

The discoveries that have made modern surgery possible, and especially the knowledge of infection, have also given us vast problems for solution, and many scientific possibilities. Pasteur once said, "In the field of observation chance only favors the mind which is prepared." And in trying to solve these problems let us study the ways of Pasteur—his humility of mind, his concentration, his diligence, and let us not be self-satisfied with our labors as was Baron Boyer, who, over one hundred years ago, declared that "surgery had then reached almost if not actually, the highest degree of perfection of which it was capable."

DISCUSSION OF DR. FALLON'S PAPER.

DR. W. P. BOWERS, Clinton: The paper which has been presented is a most difficult one to discuss because it is so complete that it leaves room only to suggest some ways by which the practice of surgery may be carried on to meet the standards already established.

The first question involved is how to select and prepare students for surgery. Medicine as you know has been for a long time a free-for-all race. There have been comparatively few hurdles or obstacles erected to prevent anybody from practising medicine. The attempt which has been made by the State to regulate medicine is only of comparatively recent years, and only went a little way. We have with us this morning the last surviving member of the group of men who tried to get the State to establish certain standards regulating the practice of medicine, and it seems eminently proper that I should refer to the gentleman on my right here (Dr. Gay) who was a pioneer in that movement designed to protect the people from the incompetent and improper practice of medicine.

Now surgery has accomplished so much that the problem today is to develop men who are able to carry on that which has already been accomplished in the way of study and practice. And how shall we do that? You say, of course, first, it is the problem of the medical school, and so it is; but are the medical schools carrying out the possibilities of the education and development of the surgeon? Wouldn't it be logical to demand that the medical schools should first study the capacity of every aspirant for surgical recognition, to determine first whether a given person has those qualifications, mental and physical, which would warrant his taking up the study of surgery? You know in the war it was the custom to examine people for definite types of service. An aviator, for example, had to go through some thrilling tests before he could be given the right to exercise that particular function, and if he failed to meet these tests he was denied the privilege. It seems equally logical to say to a young man wishing to be a surgeon that he has not the educational qualifications, and hence must be denied the privilege of practising surgery if the facts warrant this decision.

It seems to me to be first the function of the medical school to decide, and after deciding then comes the question of training. Throughout the country there is today a very serious question as to the character and quality of the interne year. Of course every surgeon from now on must be a man who has had the privilege and experience of an internship, and the question is being discussed very seriously whether the original preparation of every practitioner should not be through a rotating internship, and later those who wish to develop the specialties should take a supplementary interne service which shall fit them particularly for the specialty which they have elected to follow.

That influence and power and function of medical schools can only be exercised, however, up to a certain degree, because beyond that you must have a certain power given to the State through its representatives to select the men who shall practise the higher departments of medicine as demonstrated in surgery and other specialties. There must come a time when this simple examination, which can be made only sufficiently severe to be called fair, shall be regarded only as a preliminary examination with a further examination for the right to practise specialties. Not only the medical schools, but the State itself must determine some further qualifications than are now required of those practising medicine in its higher branches. There are certain types of practice which do require prolonged study and extensive experience and training under those who are qualified to give that advanced teaching.

These problems, it seems to me, are the problems

which face the surgeons today. The progress which has been made has placed surgery on a high plane, and that must be maintained through men who are better educated than the average practitioner.

DR. JOHN T. BOTTOMLEY, Boston: It is refreshing, perhaps I had better say it is refreshingly surprising, to find on the program of a surgical section-meeting such a title as the paper of Dr. Fallon bears. Surely it is stimulating to listen to the reading of that paper by the man who had the wit to offer it for the education and elevation of the section-members. When I was invited to take part in the discussion, I confess that I accepted with considerable hesitation; for, to tell the truth, it is not an easy matter to make comment on such a paper, nor is it a simple thing to know just what line to follow. However, as I mullied over the ideas set forth in the reader's abstract, several thoughts came to my mind.

First of all, there is most certainly a need for such papers, at least occasionally, to rouse in us the realization that we surgeons have a heritage, that it is one in which we may take a just pride and that it contains in itself much which should comfort and stimulate us in our day's task. A just appreciation of the natural moral law holds us responsible for the use we make of what we possess in the way of either body or mind, in the realm of the physical or in that of the spiritual (I use the word in its broad sense). So in a way we are bound to hold up before the mirror of our minds, for our own contemplation and emulation, the heroic figures and deeds of those pioneers in our profession who yesterday cut the paths and blazed the way that we might the more easily follow the road today. So, too, the reckoning of the surgeon really embraces his heritage. To us has been handed the torch; it is for us to hold it aloft, to brighten its flame, to broaden the light it sheds.

And then the reckoning of the surgeon! The General Secretary of the Y. M. C. A. of Chicago, with whom I have had many pleasant hours, once told me that, in talking to young men on the problems of life and work, he often expanded his theme from these three headings: (1) define your possibilities, (2) defend your possibilities, (3) develop your possibilities. His outline may well be applied to us and to our work. We should define clearly the field of surgery in which we conclude we are best fitted to labor; we should prepare ourselves adequately for work in that field; we should let nothing of lesser importance entice us away from our endeavors and we should develop our powers to the utmost limit permitted by the conditions under which we carry on. Time, thought, effort and tenacity are all required to get even a good start on the road.

May I, in closing, express a thought on what I conceive to be our duty in the matter of safeguarding the practice of surgery.

First, we must sharpen the professional conscience. We must be honest to ourselves and to the public. We must not attempt the things we are not fitted to do. We must not fail to prepare ourselves thoroughly before we begin to do. We must not cease in our efforts to uncover our weak spots and then to strengthen them by travel, by observation, by study and by work. The acquisition of a medical degree means the beginning and not the end of toil.

Second, once we have trained ourselves by the wear of our hands and the sweat of our brows for the chosen work, it is but mere justice that we should protect ourselves and our work against the inroads of those with inadequate training and just as inadequate consciences. In protecting ourselves we are only protecting the public who are entrusted to the care of the profession at large. The best of us at times fall into error and make mistakes; the worst of us come close to committing crimes.

I am satisfied that no organization alone, no appeal to the higher things of life, no court can better to a satisfactory degree the conditions that we all know exist today. We must educate the lay public

to demand that he who pretends to do surgery must be fitted to do surgery, and that he must be certified by and bear the approving mark of some organization of his peers rightfully constituted to so certify and so approve. I believe that this information must be got to the public through the usual channels by which information reaches the public—through the platform and through the press. The founding of the American College of Surgeons, no matter how dark you may personally regard the cloud under which it was born, no matter how deep the distrust you may personally feel for its master-men, methods and machinery, no matter how faulty you may think are some of its judgments, marks a long step in the right direction. The men who conceived and launched it were at least men of vision who did, while we dreamed. Not in this generation will its greatest good be had, but in the next and succeeding generations, when we and its founders alike shall have passed on. It is the only general certifying authority that exists for us, and I regard education of the public on that point as one of its great functions. I believe we should support it for the sake of distant generations. It should play a great part in the future reckoning of the surgeon.

THE TREATMENT OF TONSILS BY RADIATIONS FROM RADIUM SALTS INSTEAD OF OPERATION.

By FRANCIS H. WILLIAMS, M.D., BOSTON.

THIS paper is a report of progress. The subject is of importance not only to a large number of patients, to the surgeon and the laryngologist, but also to the general practitioner, who is the first to see many of the patients, 500,000 more or less,* who are operated upon each year in this country for the removal of the tonsils.

The basis of this use of radium is the fact that lymphoid tissue, of which the tonsils and adenoids are largely composed, is especially susceptible to its radiations, and further, that the diseased tissue in the tonsil is less resistant to them than the normal. Radium should not be depended upon to get rid of fibrous tissue or pus. The presence of pharyngitis or laryngitis, so far as I have seen, does not contraindicate the employment of radium.

In carrying out this treatment it seemed to me desirable to use the radiations of radium rather than the emanations, as the radiations are uniform in output and thus permit of accurate dosage in a simple and convenient manner.

The method is based upon measurements of the radiations, made with a fluorometer, to determine the proportion of these:

First, that would reach the tonsils through different thicknesses of aluminum;

Second, that escape through the back of the container, and would reach other parts of the throat than the tonsils;

*Tonsillectomies done in 1921 in 24 of the hospitals in Boston and seven adjoining cities, population 1,180,000, were 13,325; operations done in private practice would increase this number. On the basis of these figures, the tonsillectomies done in one year in the cities of the United States of more than 10,000 inhabitants, population 16,750,000, would be 541,240 +-. The towns of 10,000 inhabitants or less, population 79,000,000, are not taken into account.

*Surgeons in the city tell me that more tonsillectomies are done in private practice than in hospitals; this would make the number given above at least 1,000,000 instead of 500,000.

The figures relating to population were obtained through the kindness of Professor Davis R. Dowsy.

Third, that are absorbed by different thicknesses of tonsillar tissue;

Fourth, that are absorbed by the tonsillar tissue and the ramus of the jaw-bone.

These measurements showed that of the total amount of the radiations going in any other direction than the tonsil, the proportion escaping from the container used was only about 4 per cent., an amount that may be disregarded; and that of the total amount of the radiations issuing from the front of the container with a filter of aluminum 0.29 mm. thick, the proportion absorbed by 13 mm. of tonsillar tissue was a little less than 90 per cent., and that absorbed by this tissue and the ramus of the jaw was more than 90 per cent. The results of the other measurements need not be considered in detail here.

Naturally, the first thought of many practitioners would be that it is a serious matter to put radium into the throat, and to do this without carefully limiting the radiations would justify the apprehensions that were generously expressed to me by some of my colleagues when I first began to use radium for the treatment of tonsils, but these measurements show that the risk of injury to any part of the throat is negligible, if proper precautions are taken, and they have so guided my clinical use of radium that no harmful results have been noted. Among remedies of great power, I do not recall any in the use of which the action is exerted so completely where it is needed, and, at the same time, to so slight a degree where it is not desired, as is the case with radium by the method here described.

Let us now consider the clinical side. Of a group of 101 patients, the youngest was 5, the eldest 60 years of age, and in their treatment I have been guided by about twenty years' experience in the use of radium. The radium was usually applied in a silver container, about 6 mm. thick and about 16 mm. in diameter (a gold one, made for me since this was, is thinner), that has an aluminum cover 0.29 mm. thick, which acts as a filter. The container is conveniently attached to a light steel rod, that has a handle on the other end, and is covered with a new rubber cot every time it is used. Various other metal filters can be placed over the front of the container to absorb certain of the radiations. The treatments, with 50 mg. of pure radium bromide (26 mg. of radium element), were of about 20, 15, or 10 minutes' duration for each tonsil, according to the filter used, which was of aluminum 0.87, 0.58, or 0.29 mm. thick, respectively. I say "about" advisedly, because the length of treatment depends upon the patient's condition, the size and character of the tonsil, and what one has in mind to accomplish. In some patients there was reason for exceeding these doses; three among them had a moderate reaction for two or three days, but this was not enough to interfere with

their usual diet or occupation. Good results may be brought about without causing discomfort.

The application of radium is simple for the patient. He has only to keep his mouth open while the physician holds the container against the tonsil. The container may be removed at intervals, in order to allow the patient to swallow saliva. If the throat is sensitive, a solution of cocaine may be used; in the majority of cases this has been unnecessary. As a rule, children cooperate readily.

Immediately after the treatment no especial change is noted; sometimes improvement begins promptly, and after two or three days, more or less, there is an exudation from the tonsils, which may continue for some time. Some kinds of tonsils diminish in size very strikingly within a few days, others very slowly. In a very few patients the tonsils have largely disappeared after one treatment, in others three longer applications, given at intervals of weeks, did not give as much result. Enlarged glands show improvement. In some cases the patient's general condition should guide us to the use of radium even when the appearance of the tonsils does not suggest it.

Improvement in the general condition, often marked diminution in the size of the tonsil, after only one treatment, and that not given in large amount, indicates that in a certain number of cases it may be sufficient to carry the treatment only far enough to obtain good drainage.

The earlier patients did not have as much treatment as I now use, but there has been some improvement, locally or otherwise, in nearly every one, with no interference in any case with the customary meals or occupation. The statements of patients, suffering from poisons originating in the tonsils, of improved well-being, alertness instead of lassitude, and desire instead of disinclination for work, have been the rule. It has been difficult to follow some of the patients for any length of time; they were treated, improved, were seen once or twice, and then disappeared. Of those who were treated more than a year ago there are only good results to report.

The following cases were not average ones, but show a striking response to radium treatment in adults:

Mrs. X., 60 years of age, had a succession of four severe colds during the winter; had her teeth x-rayed and as a result of this examination four of them were extracted, but she got no relief. She was below normal in her activities and well-being, and had a slightly ashen complexion.

The right tonsil was on a line with the pillars of the fauces, and the left extended 3 mm. beyond the pillars, was large and discharging, and the gland on that side was large and sensitive. I applied the radium to each tonsil for about 10 minutes, without the use of cocaine.

Within forty-eight hours after the treatment she was much improved and the gland had lost its sensitiveness. The third day after treatment the left tonsil was much reduced in size, and there was a concave instead of a convex surface in the part of the tonsil that had contained small masses of a pus-like material. The right tonsil was also reduced in size. Her improvement was evident in her voice and manner, and in the eyes and the color of her skin.

On the seventh day after treatment the gland had disappeared and both tonsils, especially the left, were greatly reduced in size. She had not had the slightest pain or even discomfort, and there was no change in the daily routine of her life except for the better. On the twenty-first day the tonsils had largely disappeared. When last heard from, six months after the first treatment, she was in excellent health and spirits. This case suggests that in some instances radium treatment, before extracting teeth or doing tonsillectomy, might render these procedures unnecessary.

Mr. Y., 48 years of age, was "crippled with rheumatism," by reason of which he had given up work for 8½ months. The tonsils were submerged and were not visibly enlarged. Both were treated with radium and a profuse exudation resulted.

Within a week he had some relief from rheumatism, in about two weeks he was much improved, and in one of the worst storms of the winter, a day on which he would not have ventured out before he had had radium treatment, he walked 1¼ miles to the station and came to Boston to keep his appointment. After two weeks, he expressed himself as being in excellent physical condition, his eyes were bright and his color good. Four months after treatment, when last seen, there was still further improvement in his appearance, there had been no recurrence of the arthritis, and he said that he felt like a new man.

Mrs. E. M., 37 years old. On December 9, 1921, she gave a history of repeated attacks of tonsillitis with arthritis. The tonsils measured 1.5 cm. high by 1 cm. wide. Radium was applied to each tonsil without the use of cocaine. On the fourth day she had marked relief from the arthritis; the tonsils were smaller, and there was no irritation in the throat. On the twenty-first day she felt well, had no sore throat, and no arthritis; the tonsils were slightly smaller. Three and one-half months later, the patient was very well indeed, and the tonsils had disappeared. Six months after treatment she was still free from arthritis, and the throat was in fine condition.

The following case is in contrast to those just cited:

Miss Z. had recovered from an attack of arthritis, but had acute tonsillitis when she

received radium treatment. After one application of this remedy to the tonsils, they were reduced to a very small size and gave no further trouble, but as four weeks later there was another attack of arthritis, a severe one, tonsillectomy was done without my being consulted, the small size of the tonsils greatly facilitating the operation, yet neither operation nor radium prevented a recurrence of arthritis; in less than three weeks after the operation she had another attack, followed in about four weeks by still another. At this time an x-ray examination showed abscesses around two teeth; since the removal of these teeth three months ago she has had no further attacks of arthritis. This case suggests that we may be able to infer, by the application of radium, whether or not certain complications have their origin in the tonsils, without resorting to tonsillectomy.

During the past winter, the house officers at the Boston City Hospital have chosen radium treatment instead of tonsillectomy, except one who had decided on operation before he appreciated what radium could do. He, however, chose radium for the removal of the part of the tonsil left after operation. This small group of seven have since been free from their customary attacks of tonsillitis.

Of these 101 cases,

44 had enlarged tonsils;

33 had tonsillitis; 2 acute, 31 with history of recurrent attacks;

24 had enlarged or otherwise diseased tonsils, with complications as follows:

14 arthritis

7 cardiac disease

1 cardiac disease and arthritis

2 nephritis

Of the 44 cases with enlarged tonsils, the tonsils were reduced in size in 41 cases; in 3 they were not reduced.

Of the 33 cases of tonsillitis, the tonsils were reduced in size in 31 cases; the remaining 2 cases were lost sight of.

Of the 14 cases with arthritis, in 11 the arthritis diminished or disappeared; in 1 it remained; in 1 it recurred after both radium and tonsillectomy, but had not recurred, when last heard from, after the extraction of two teeth; 1 died of pneumonia.

Radium treatment, of course, had no effect on the old cardiac disease of the 7 cases noted.

The case of cardiac and arthritic trouble, and the 2 cases of nephritis, were lost sight of.

Radium is a powerful agent both for harm and for good. The physician should be well-informed about radium before he ventures to apply it; otherwise he may do harm to some patients, or fail to do the good that should be accomplished. Professional training and experience are required to determine the conditions under which it should be employed for treating the tonsils, and the amount and quality of the radiations which should be used.

Radium is useful for children, and especially so for adults, to whom operation may bring great discomfort and serious danger, and possibly death; as well as for those who, on account of cardiac or other disease, are not suitable subjects for operation.

The radiations from radium salts are, I believe, more suitable for the treatment of tonsils than the x-rays, because the former are uniform in output and thus permit of accurate dosage; and further, because the radiations from radium salts are applied through the mouth to the tonsil and are nearly all absorbed by the tonsil itself, whereas measurements of the x-rays, made with a fluorometer, show that these rays, being applied from the outside of the jaw to the tonsil, are absorbed to a large extent by the intervening tissues, where they are not desired, the parotid gland being especially susceptible to them, before they reach the tonsil.

I have shown chiefly thus far that the method here presented is harmless; that tonsils have been reduced in size; that recurrences of tonsillitis have been prevented, and that some patients suffering from arthritis have been relieved.

DISCUSSION OF DR. WILLIAMS' PAPER.

DR. GEORGE W. GAY, Chestnut Hill: Dr. Williams' interesting paper, coming as it does from a pioneer in the therapeutic use of diphtheria antitoxin, the x-ray and radium, merits the thoughtful attention of the profession. In over a hundred cases of enlarged, inflamed, or otherwise diseased tonsils he has succeeded in reducing the size and the inflammation in a very large proportion by exposure to the direct radiation of radium. In 77 uncomplicated cases of enlarged and inflamed conditions of these organs a practical cure was obtained in 72 instances and two cases were lost sight of. A painless, non-operative method of treatment of these affections that proves successful in 93 per cent. of the cases is certainly worthy of consideration.

Radium not only has a distinctly beneficial effect upon the size and condition of the tonsil, but the crypts, which are the favorite resort of noxious germs, are obliterated, thus closing what is considered by many authorities a ready avenue by which the products of these bacteria enter the system. If the modern theory that certain diseases, as the so-called rheumatic affections, find entrance through the tonsils be correct, then the importance of destroying this avenue of approach becomes strikingly apparent. Should time and further experience confirm Dr. Williams' admirable results, the radium treatment of diseased tonsils must be considered a distinct advance in therapeutics. There are good reasons for anticipating this desirable result.

Another important feature in Dr. Williams' work is the fact that his scientific attainments, derived in part from his long and intimate connection with the Massachusetts Institute of Technology, of which institution he is a graduate, enable him to determine the ratio of the direct radiation of radium upon the desired area, to the indirect effect, the back kick through the container, of this agent upon the surrounding tissues. He is, thereby, able to remove certain objections that have been advanced against the use of radium in the throat. Another objection that has been made against its use in the throat is that we do not know the ultimate results of the treatment extending over three or four years. From the fact that seventeen years' experience with the agent upon the skin and a year and a half's experience in the throat

have produced no untoward results, this objection would seem to be more academic, more theoretical than practical. Properly used, this remarkable agent would seem to have no deleterious effects, even in those rare instances in which no benefit results from its use.

One important fact in the use of radium should be constantly borne in mind and that is the marked difference in the reliability of the radiations of radium itself and the emanations from a solution of the substance in water. The former are permanent and unchanging; the latter soon lose their power and are useless. Radiation, and not emanation, is the only unailing source of radium effects.

Of course you are all familiar with the happy effects of this agent upon various affections of the skin, as the epitheliomas, moles, birthmarks, etc. My personal experience is confined chiefly to the epitheliomas. The results have been most satisfactory. In the early days of radium an epithelial growth upon my face of three or four years' duration was subjected to five exposures of radium with no discomfort whatever. The crust came off in a short time, leaving a smooth, normal surface and there has been no return for 15 years. So many favorable results have come to my notice that I should hesitate to recommend a surgical operation for the removal of these growths, if proper treatment by radium were available.

In conclusion allow me to say that a painless, safe, efficient and non-operative method of treating diseases of the tonsils that is successful in more than 90 per cent. of the cases, is worthy of the serious consideration of the profession. Dr. Williams' admirable work merits the highest appreciation of the physician and the public.

DR. C. R. C. BORDX, Boston: I desire to congratulate Dr. Williams on the splendid results which he has obtained by this new method of treating diseased tonsils. The percentage of successes which he has had is remarkably large and I feel disappointed in the results of my own experience.

Toward the close of last year, I was visited by a gentleman who represented one of the large radium companies of the United States. He had been calling upon the various nose and throat specialists to interest them in radium as a substitute for operation on the tonsils. After a consideration of the matter I asked him to treat a series of cases with radium and then allow me to remove the tonsils and study them with regard to their condition. This he agreed to do.

The speaker today has made the statement that the screening of radium is an easy matter.

With regard to this point I should like to report a recent experiment conducted by Doctor L. J. Walker of Boston. He purchased six needles of radium, each containing ten milligrams. As a means of safety these needles were kept in a circular lead case with walls nearly half an inch in thickness. To test the penetrating power of the radium he placed the lead case containing the six needles in a steel safe. In a filing-cabinet in the next room with a thick wall between he placed a photographic plate upon which was suspended a pair of surgical scissors. The following morning the plate was found to show a perfect image of the scissors. Thus, the rays had penetrated the lead case, the steel wall of the safe, the wall dividing the rooms, the wall of the filing-cabinet and the several air spaces between.

The terrific penetrating power of radium as shown by this experiment so alarmed me that I hesitated to employ it within the mouth, and turned my attention to the x-ray which affords a similar and much better known treatment.

It had been known for some time by members of the nose and throat profession, that x-ray was being used by the Rockefeller Institute and Dr. Wetherbee of New York. Dr. Paul Butler and I went to New

York and called upon Dr. Wetherbee. He was exceedingly cordial and frank. He described his large number of cases; gave statistics; showed us his apparatus, and furnished us with his working data as to dosage, spark gap, time of exposure, etc. He also described minutely the early work at the Rockefeller Institute, and generously instructed us how to proceed in a scientific research from the point where he left off.

On our return to Boston we arranged to continue the work for the purpose of determining, if possible, whether or not it was successful and clinically worth while. Dr. Frank L. Richardson offered his services for the anesthesia, a sacrifice of time which was greatly appreciated, since it afforded the best possible opportunity for minute observation during the operations. Dr. Butler, of course, carried on the x-ray work.

The first case was that of a young girl with a semi-acute ear which was discharging freely. Her throat was red, and her tonsils were somewhat enlarged and inflamed. In this case we used one application of the x-ray. Forty-eight hours later I found the ear to be nearly well; the tonsillar inflammation had subsided to a marked degree, and I thought at the time that the tonsils had considerably decreased in size. In looking back over the series of cases treated, I am inclined to think that the supposed reduction in the size of the tonsils was largely imagination. The effect upon the ear, however, was real and remarkable. Four days later I removed the tonsils without any bleeding whatsoever. The operation in the next four cases was also practically bloodless, but one sponge being used in the first five cases. The sixth case bled profusely, requiring the use of many sponges. This case, however, may not have been a fair subject for the series, since two years before the patient had been very ill for several months with black smallpox at her home in Cairo, Egypt, and at the time of our treatment and operation her general physical condition was not particularly good.

If I remember rightly, we treated sixteen cases with x-ray and I operated upon fourteen. The number of treatments varied from one to four. Undoubtedly the x-ray treatments decreased the hemorrhage somewhat, but in that respect one application seemed better than two or more. My own experience is that tonsils treated by x-ray exposure do not decrease much in size. Although on inspection they appear to be smaller, yet when removed they are fully as large as before and in some instances decidedly larger.

The tonsils removed during this series of cases have been preserved. They will be sectioned and studied by Dr. Mallory. When his report is received, we shall have something definite upon which to base a scientific conclusion, but until that time it must remain a matter of opinion.

Personally, I feel, at the present moment, that neither x-ray nor radium has any lasting influence on chronically diseased tonsils which are filled with pus pockets, and that careful dissection and removal are the only means of permanently dealing with them.

Tonsils which the x-ray seem most to benefit were often found, at the time of operation, to be the worst. Some of them are mere bags of pus, and two of them even burst from the pressure of the grasping forceps; yet prior to the time of the operation these tonsils appeared to have become smaller, whiter, and smoother in outline.

If the tonsils treated by Doctor Williams have atrophied to such a point that infection is no longer present or possible, he has accomplished that which will confer an untold blessing upon countless thousands who will escape operation on the tonsil and the discomforts attending upon it. But, may I ask, can we accept Dr. Williams' opinions which are based

upon inspection alone, or upon a more or less temporary cessation of symptoms?

DR. WILLIAMS (in reply to Dr. Borden): I may have met the same representative of a radium company who saw Dr. Borden. Before answering Dr. Borden's question, I need a little more information; may I ask Dr. Borden how much radium this representative used, and what the quality of the radiation was?

As regards the radium picture of the scissors, it was taken after a very long exposure and by the gamma rays, which form a very small percentage of the radiations from radium, but have great powers of penetration. I tested radium more than 18 years ago and found that, when held on the chest, it would set up fluorescence on a suitable screen placed on the back; I then tried iron and steel, but I did not have enough at hand to absorb the radiations. Then I tried lead, which is far more impenetrable to the radiations than iron or steel,—one inch, two inches, three inches of solid cast lead—and still some radiations went through. In other words, a very small amount of penetrating rays, with a very long exposure, will take a photograph, but a small amount of these rays for a few minutes may be disregarded as to danger.

After 26 years' experience with the X-rays I know that they are very useful. Their disadvantage is their uncertain dosage. You may put the same amount of energy into different X-ray tubes, as far as you can measure it by the spark gap and the current, and yet get different amounts of X-rays issuing from these tubes, or you can put the same tube on different measurements as to spark gap and current, and yet not get the same amount of X-rays. Therefore, I say that the dose of X-rays is uncertain; X-rays may vary in quality as well as in amount. With radium, on the contrary, one may get radiations of the same amount and of the same quality.

DR. BORDEN (answering Dr. Williams's question): I think you misunderstand me as far as my associations with this man go, for I had no cases with him. He handled cases in this town for other men. He told me that his plates contained 30 milligrams and that they were guaranteed by the United States Government to be pure radium and to be that weight. He, furthermore, told me that most of the radium in use had not been so standardized by the Government, and that very few people knew what was in it.

As regards the measurements of X-rays, it seems to me it would be possible to buy standardized machines and know exactly the spark gaps.

DR. ALEXANDER FORBES, Milton: I should like to ask Dr. Williams if it is possible to measure accurately the quantity of emanation by the modern electrical methods, and wonder why it is not quite as accurate to use measured emanation as it is to use the radium itself.

DR. WILLIAMS (in reply to Dr. Forbes): The radiations from the emanations of radium can, of course, be measured, but they lose one-half their strength in less than four days, and this process of decay continues; whereas the output in quantity and quality of the radiation from radium salts is uniform.

DR. CARL PHIPPS, Boston: I think we cannot depend upon the appearance of the tonsil alone but we can note the general feeling and the general condition of the patient in regard to joints, headaches, sore throats, etc. I am speaking from the experience of two or three patients I have had occasion to refer to Dr. Williams, and also in my own case. I had reached the stage in my own tonsils when I felt that I must have an operation. I put it off and finally I had Dr. Williams apply radium. They shrunk down to white, small, bodies, and I was re-

lieved of the unpleasant rheumatic symptoms which were putting in appearance, and my general health improved. I know the same thing is true in the case of some of my patients.

DR. H. V. REYNOLDS, Brookline: I have had several cases in adult women with tonsils diseased who refused positively to have tonsillectomy done and had radium. There was no unpleasant reaction, and the tonsils gradually melted away with no unpleasant symptoms or discharge, and with the improvement in each case such as I had seen following tonsillectomy. In fact, I could see no difference in the after-condition of the patients in tonsillectomy or removal by radium, except that there is a little contracted fibrous tissue at the base of each of the tonsils. The glandular part seemed to have disappeared.

Each patient was an intelligent woman, and each one is satisfied with the improvement that she has noticed from this treatment.

A MEMBER: There were four cases in my outpatient department where I had radium applied to one tonsil only. It was done by the same gentleman of pleasant appearance, to whom Dr. Borden has referred. In three weeks to three months all the tonsils were removed and you could not tell the difference, even in the microscopic examination. There was no shrinkage and there seemed to be no results from the radium.

DR. WILLIAMS (closing): It seems to me that it is well for a physician to know what goes into the X-ray tube, and also important for him to know what comes out of it.

CINCINNATI UNIVERSITY HONORS DONORS OF LARGE GIFTS TO MEDICAL SCIENCE.

In honor of John D. Rockefeller and Andrew Carnegie, the board of directors of the University of Cincinnati has established two chairs to bear their names in the College of Medicine.

The obstetrics department will be known as the John D. Rockefeller Chair of Obstetrics, and the professorship in biochemistry will be the Andrew Carnegie Chair of Biochemistry.

The University of Cincinnati is said to be the first large university or college in the country to thus honor the names of Rockefeller and Carnegie for efforts made to advance science and education. It was declared that both the Rockefeller Foundation and the Carnegie Foundation, which are endowed heavily, had shown great interest in the scientific attainments of the university.—*The Ohio State Medical Journal*.

CAMPAIGN AGAINST MOSQUITOES.

THE Board of Conservation and Development in New Jersey has recommended the appropriation of one million dollars to be used over a period of five years against the mosquito.

It is claimed that when the State shall have been cleared of mosquitoes the property value of the State would be increased by five hundred million dollars.

New England Surgical Society.

Provisional program of the meeting of 1922, to be held at Burlington, Vermont, Friday, September 22, and Saturday, September 23:

FRIDAY MORNING.

9.00 A.M. Clinic at Mary Fletcher Hospital, Burlington.

12.30 P.M. Lunch at Hotel Van Ness, as guests of the Vermont members of the Society.

FRIDAY AFTERNOON, 1.30 O'CLOCK.

Hotel Vermont—Roof Garden.

Hare Lip.—William E. Ladd, M.D., Boston.
Tuberculous Cervical Adenitis in Children.—James S. Stone, M.D., Boston. Discussion: opened by Dr. Frederick Hussey and Dr. Charles G. Mixer.

A New Operation for Retroversion of the Uterus.—John W. Keefe, M.D., Providence, R. I.

Carcinoma of the Cervical Stump.—Lincoln Davis, M.D., Boston. Discussion: opened by Dr. Lyman Allen and Dr. Herbert L. Smith.

Some of the Lessons Learned from a Series of 500 Prostatectomies.—Arthur L. Chute, M.D., Boston.

The Importance of Pyelography in Recognizing the Causes of Obscure Abdominal Symptoms.—Richard F. O'Neil, M.D., Boston.

The Silent Kidney.—J. Dellinger Barney, M.D., Boston.

Kinks of the Ureter.—Arthur H. Crosbie, M.D., Boston. Discussion: opened by Dr. William W. Townsend and Dr. S. B. Overlock.

4.00 P.M. Boat ride on Lake Champlain—Steamer Ticanderoga. Wives and children of members are invited.

7.00 P.M. Annual Dinner on board Steamer Ticanderoga. Address of the President, "Progress in Surgery Overseas," Dr. George E. Armstrong, Montreal.

SATURDAY MORNING, 9.00 O'CLOCK.

Business Meeting.

Local and General Anesthesia in Strangulated Hernia.—Edward P. Richardson, M.D., Boston.

The Results of Anesthesia in My Own Service.—Halbert G. Stetson, M.D., Greenfield, Mass. Discussion: opened by Dr. Alfred M. Rowley.

Myeloma of the Spine.—Robert B. Osgood, M.D., Boston.

Myositis Ossificans Traumatica.—Dudley Carleton, M.D., Springfield, Mass. Discussion: opened by Dr. William C. Peters and Dr. Jason Mixer.

NEW "WRINKLES" IN SURGERY.

(Five Minute Topics)

A device for hemostasis and drainage following suprapubic prostatectomy.

A method of implanting radium needles in tumors of the bladder.—John M. Cunningham, M.D., Boston.

The Anal Button for relief of post-operative tension in the Colon.—Ralph W. French, M.D., Fall River, Mass.

Pre-Operative and Post-Operative treatment of toxic myocarditis associated with gall-bladder disease.—Frederick V. Hussey, M.D., Providence, R. I.

Skin Grafting in two stages.—Charles A. Porter, M.D., Boston.

Injuries to the Spleen: including wounds and ruptures of that organ.—Eugene Pool, M.D., New York

City (by invitation). Discussion: opened by Dr. Charles A. Porter.

Diverticulum of the Oesophagus.—Frank H. Lahey, M.D., Boston.

Report of a Case of Diverticulum of the Oesophagus.—Lucius C. Kingman, M.D., Providence, R. I.

Myoma of the Stomach.—Ernest L. Hunt, M.D., Worcester, Mass. Discussion: opened by Dr. Fred B. Lund and Dr. John M. Gile.

12.30 P.M. Lunch at Hotel Vermont.

SATURDAY AFTERNOON, 2.00 O'CLOCK.

Intestinal Obstruction by Enteroliths.—Charles R. Abbott, M.D., Clinton, Mass. (by invitation). Ernest L. Hunt, M.D., Worcester, Mass. Discussion: opened by Dr. P. P. Johnson and Dr. George A. Matteson.

Arterioenteric Obstruction of the Duodenum.—Henry C. Tinkham, M.D., Burlington, Vt. Discussion: opened by Dr. John T. Bottomley and Dr. Charles G. Mixer.

Post-operative Intra-Abdominal Adhesions.—Ralph H. Seelye, M.D., Springfield, Mass. Discussion: opened by Dr. George M. Sabin and Dr. J. C. Hubbard.

NEW "WRINKLES" IN SURGERY.

(Five Minute Topics)

Enterostomy as a safety valve in connection with Intestinal Suture.—Daniel F. Jones, M.D., Boston.

Home-Made Catgut.—Michael J. Fallon, M.D., Worcester, Mass.

Title to be announced.—Ernest T. Wells, M.D., Hartford, Conn.

Title to be announced.—John B. Wheeler, M.D., Burlington, Vt.

Death under general Anaesthetics.—George B. McGrath, M.D., Boston (by invitation).

Surgery in Diabetes.—Arthur T. Jones, M.D., Providence, R. I. Discussion: opened by Dr. William H. Bradford.

Hernia from the Employer's Standpoint.—Robert J. Graves, M.D., Concord, N. H.

Post-operative swelling of the upper extremity following operations on the breast and axilla.—Willis E. Hartshorn, M.D., New Haven, Conn. Discussion: opened by Dr. S. A. Mahoney and Dr. H. G. Stetson.

OFFICERS FOR 1922: President, Charles A. Porter, Boston, Mass.; vice-president, Herbert L. Smith, Nashua, N. H.; secretary, Philemon E. Truesdale, Fall River, Mass.; treasurer, Peer P. Johnson, Beverly, Mass.

EXECUTIVE COMMITTEE: Lyman Allen, Burlington, Vt.; John W. Keefe, Providence, R. I.; John F. Thompson, Portland, Me.; Seldon B. Overlock, Pomfret, Conn.; David W. Cheever, Boston, Mass.

CENSORS' MEETINGS.

The Censors for the several districts will meet for the examination of applicants for fellowship on the first Thursdays of May and November.

The Censors for the Suffolk District will examine applicants residing in that district and also applicants who are non-residents of Massachusetts.

Applicants for fellowship should apply to the Secretary of the District Society of the district in which they reside (have a legal residence) at least one week before the date of a given examination, taking with them their degrees in medicine.

Book Review.

Tuberculosis and the Community. By JOHN B. HAWES, 2D. Lea and Febiger: 1922, 163 pages.

In this presentable volume of modest size, Dr. Hawes deals with tuberculosis as it affects the community. It is not written purely for the medical profession or for the layman, but for any who may be interested in community health as it is affected by tuberculosis. The style is readable, the subject-matter clear to physician or layman, facts are plainly set forth, and important details are not neglected.

The cost of tuberculosis to the community, an argument that generally carries weight, is vividly expressed. The parts that various factors play in the battle against this disease are taken up in detail; hospitals and sanatoria, dispensaries, after-care, the nurse, schools, housing, occupations. Concrete advice is given in the chapters on a Tuberculosis Program for Small Cities and Towns, and Present Needs of the Tuberculosis Campaign.

The writer is to be congratulated on having covered such an important subject so thoroughly in such a few pages. A readable and instructive book, it fortunately lacks that formidableness of size that is so often a deterrent to perusal.

The Massachusetts Medical Society.

MEMBERSHIP CHANGES FOR THE MONTH OF AUGUST, 1922.

OFFICIAL LIST (7TH).

Compiled by the Secretary.

ALPHABETICAL LIST.

Allen, Harold M., Lawrence, office now Room 503, Bay State Building.
Austin, A. Everett, Boston, from 141 Commonwealth Ave. to 270 Commonwealth Ave.
Baker, Chester Stoyte, Lowell, now 10 Merrimack Sq.
Blake, John Baptist, Boston, office now 371 Commonwealth Ave.
Bryant, Mason David, Lowell, office now 9 Merrimack St.
Chaisse, George E., Lowell, office now 759 Merrimack St.
Carr, Gladys L., from Weymouth to Dubuque, Iowa, 253 W. 10th St.
Clare, Wendell Phillips, from Boston to Chelsea, U. S. Marine Hosp. No. 2.
Cunningham, Joseph Henry, died at London, England, August 28, 1922, aged 55.
Dudley, Oscar A., from Pittsfield to Cochituate (Wayland), office Worcester, 611 Park Building.
Everett, Willard S., from Newton Upper Falls to New York City, 363 First Ave.
Feldman, Louis, Boston, office now 360 Commonwealth Ave.

Foot, Nathan C., from Milton to Cincinnati, Ohio, 140 East Interwood Ave.
Gage, Fred Leon, Lowell, office now 9 Central St.
Gibson, David Howard, from South Boston (Suffolk) to Cambridge, 76 Reservoir St. (Middlesex South).
Glickman, Alfred Myron, from South Boston (Suffolk) to Springfield (Hampden), 176 Chestnut St.
Guibord, Alberta S. B., office now Boston, 210 South St.
Hamilton, Wallace F., from Newton to Wellesley, 3 Denton Road.
Howard, Margaret E. P., from Reading (Middlesex East) to Roxbury (Norfolk), New Eng. Hosp. for Women and Children.
Hymen, Max H., Lowell, now 174 Central St.
Lanpher, Howard A., from Chester to Hartford, Conn., 61 Rosemont St.

SUBSCRIPTION TERMS: \$5.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

THREE FACTS CONCERNING THYROID DISEASE.

THE modern conceptions of thyroid disease have been presented from time to time in the columns of this JOURNAL. Certain facts, however, concerning certain aspects of thyroid conditions stand out as of extreme importance to the physicians who are first called to give advice. The first is the necessity of having in mind the possibility of sub-sternal or intrathoracic goiter in all nodular enlargements of the thyroid. This is a condition which distinctly adds to the risk of the operation, and one which may be obviated by the early removal of all low-lying nodular goiters tending to extend beneath the sternum or clavicle. The second fact which should be kept in mind is that malignancy of the thyroid occurs practically always in adenomata of the thyroid which have existed benignly for some years; that there are no features from which the transition to malignancy may be suspected; that when malignancy is present a fatal outcome is almost certain. Hence the removal of benign adenomata of the thyroid in those patients approaching or within the cancer age is even more urgently indicated than in breast tumors, where the percentage of cancer cures is very much higher. Third: Regardless of the views held as to the most desirable method of treatment for thyroid disease,—rest, radiation or surgery,—patients should not be permitted to continue with unfavor-

able progress under any form of treatment until they reach a stage of such intense toxicity that no active measures whatever are possible. Active surgical measures should be undertaken, in cases which fail to improve with other forms of treatment, before such a lamentable and often fatal condition is reached.

EXPERT TESTIMONY IN COURTS.

At a joint meeting of the Hennepin County Medical Society of Minnesota and the Hennepin County Bar Association, the following resolution was adopted:

RESOLUTION—

JOINT COMMITTEE OF LAWYERS AND PHYSICIANS.

1. WHEREAS, there is evidence of a growing dissatisfaction with the present method of adducing expert medical opinion offered in the trial of civil and criminal actions, and

2. WHEREAS, such dissatisfaction is due very largely to the heavy burden upon litigants for expert advice; the prolonging of trial work; and the uncertainty of outcome and difficulty of settlement due to the irreconcilable conflict in the testimony on the opposing sides of the case, and

3. WHEREAS, this situation has developed to such an extent that comment by the trial courts and also the courts of last resort, and by others having knowledge of the facts, is taking on a character tending to cast reflection upon the skill and integrity of the members of the medical profession and legal profession, and

4. WHEREAS, with a view of correcting this situation in so far as may be practicable, a joint committee of the physicians and the lawyers has been making a study of this subject for the purpose of working out and proposing some concrete plan or method to be used in connection with trial court work as a means to remove as far as possible this dissatisfaction.

5. NOW, THEREFORE, BE IT RESOLVED by the members of the Hennepin County Bar Association, and by the members of the Hennepin County Medical Society in joint meeting assembled on May 6, 1922, that all physicians competent to qualify as expert witnesses upon the various subjects in litigation, shall be named annually by the Hennepin County Medical Society, from which number any trial judge, or any one or more of the litigants in any suit, may select a commission of three or more physicians to conduct a joint examination for the purpose of furnishing expert testimony relating thereto.

6. PROVIDED, HOWEVER, that any selection and appointment of any such commission by the court shall be made only upon stipulation of the litigants, and in any case where the litigants cannot agree upon the three names, each

side may select one physician with provision that the two physicians so selected may select a third.

7. BE IT FURTHER RESOLVED, that the compensation for any services rendered in making any such examination, or giving expert testimony concerning same, shall be based upon a schedule to be designated by resolutions of the Medical Society and in no case shall the physicians who make such examinations, or give any such testimony, be permitted to know from what source their compensation is derived, such compensation to be payable through the Clerk of the District Court, or if that is not practicable, then through some trustee.

8. BE IT FURTHER RESOLVED, that it is the intention by this procedure to abolish the established relation of paid employee between any litigant and the physician or physicians giving such testimony in order to secure as far as possible impartial and unprejudiced testimony.

9. BE IT FURTHER RESOLVED, that any physician giving testimony in any case under this arrangement shall be subject to cross-examination under the usual rules by any one or more of the litigants in the case.

The following circular was sent with an explanatory note to each member of the society by the president, to be filled in and returned for use in making up a list to be recommended to the courts:

HENNEPIN COUNTY MEDICAL SOCIETY EXPERT CERTIFICATE AND DECLARATION.

The present method of obtaining expert medical opinion is unsatisfactory. I, therefore, believe that the plan as outlined in the resolutions passed at the joint meeting of the Hennepin County Bar and Hennepin County Medical Societies, May 6, 1922, should be followed until some law is enacted that will make it possible for all expert medical opinion to be given by a neutral commission.

I will be willing, under the resolutions adopted by the two societies, to act as a member of a neutral commission on expert testimony in the trial of civil and criminal actions.

Of the divisions of practice hereinafter specified, I am qualified to act as an expert in the ones checked:

- | | |
|----------------------|---------------------|
| 1—General Medicine | 9—Skin and Venereal |
| 2—General Surgery | 10—Genito-Urinary |
| 3—Orthopedics | 11—Obstetrics |
| 4—X-ray and Radium | 12—Gynecology |
| 5—Eye and Ear | 13—Anatomy |
| 6—Nose and Throat | 14—Physiology |
| 7—Nervous and Mental | 15—Pathology |
| 8—Pediatrics | 16—Bacteriology |
| | 17—Chemistry |

I hereby promise to carefully examine and scientifically investigate any case for which I

am selected to testify as one of a commission of experts; to give expert opinion only in such branches as I have named, after consultation with other members of the commission; and to give an impartial report or opinion, if cross-examined, according to the best of my scientific knowledge and belief.

(Signed) JOHN DOE.

Following is the resolution relating to fees for expert testimony, adopted by the Executive Committee of the Hennepin County Society:

FEES FOR EXPERT TESTIMONY BY COMMISSION.

Be it resolved by the Executive Committee of the Hennepin County Medical Society that the fees for expert testimony by Commission, as per resolutions passed by the Joint Meeting of the Hennepin County Bar Association and the Hennepin County Medical Society, May 6, 1922, be at the rate of \$50.00 for each one-half day, or fraction thereof, consumed per member, as the minimum fee, and the maximum fee to be determined by the responsibility and importance of the case.

—P. W. W.

—*Minnesota Medicine*, Vol. 5, No. 9.

This method is devised for the purpose of securing justice and is commendable from the standpoint of ethics. For a long time there has been a feeling of dissatisfaction relating to expert testimony submitted by physicians. Because of the inability an honest expert sometimes experiences when he is trying to give information, eminent lawyers have deplored the custom which has prevailed, but have felt that any changes might not be in conformity with the principles underlying court procedures. Since the resolutions appearing above have been endorsed by a bar association we may hope that a solution of the problem has been found.

This subject has been discussed in this State, but up to the present time nothing has been done because, according to some lawyers, no plan has been devised which would assure full rights to a defendant in a criminal action. The theory of law seems to be that so long as a defendant's witnesses testify in conformity with the rules of evidence there can be no objection to the use of independent experts.

The action of the Hennepin County physicians and lawyers has only found expression in the form of resolutions thus far. The next question is as to whether the courts will endorse these resolutions and apply them in practice, and then still further, whether attorneys will restrict testimony to experts selected under this plan, for if lawyers are at liberty to ignore the resolutions the system will fall down. The practice in Minnesota courts will be followed with interest.

NEWS ITEMS.

THE BOSTON TUBERCULOSIS ASSOCIATION. The Boston Tuberculosis Association removed its offices on September 1 to Nottingham Chambers, No. 25 Huntington Avenue, just beside the Boston Public Library. Its new offices are in accordance with the modern policy of living in sunshine and fresh air. The rooms are on the sixth floor, high up above Huntington Avenue, and look out upon the end of the extension of Stuart Street and the free space about the Boston and Albany Back Bay station. The Association has been since 1903 on Joy Street, where it has had quarters in the Twentieth Century building. With the increasing contact with business organizations and the coming to the rooms of more and more workers, the Association has felt the need of being in a business location, and it has settled itself just at the border of the coming commercial district in the Back Bay.

It is with regret that the death is announced of Dr. Alexander Richter Craig, secretary of the American Medical Association, which occurred Saturday night, September 2, 1922, at Port Deposit, Maryland.

RECENT APPOINTMENTS.—Children's Hospital, Associate Physicians: Dr. James M. Gamble and Dr. Richard M. Smith. Assistant Visiting Physicians: Dr. Lyman A. Hoag and Dr. Arthur Goulding. Infants' Hospital, Visiting Physician: Dr. Richard M. Smith.

STOLEN CERTIFICATE.—Dr. John O. Caldwell of Sharon has had his certificate of registration as a physician in Massachusetts stolen from him.

WEEKLY DEATH RATE IN BOSTON.—During the week ending September 2, 1922, the number of deaths reported was 185 against 171 last year, with a rate of 12.63. There were 36 deaths under one year of age against 38 last year. The number of cases of principal reportable diseases were: Diphtheria, 47; scarlet fever, 14; measles, 14; whooping cough, 32; typhoid fever, 3; tuberculosis, 35. Included in the above were the following cases of non-residents: Diphtheria, 6; scarlet fever, 5; whooping cough, 2; typhoid fever, 2; tuberculosis, 9. Total deaths from these diseases were: Diphtheria, 1; scarlet fever, 1; whooping cough, 4; tuberculosis, 14. Included in the above were the following cases of non-residents: Diphtheria, 1; scarlet fever, 1; tuberculosis, 2.

CHANGE OF OFFICE.—Dr. John Warren Saver announces that he has moved his office to 321 Dartmouth Street, Boston.

BABIES WEIGHED AT WEYMOUTH FAIR.—An interesting and novel health demonstration was given at the recent Weymouth fair on September 1 and 2 by Miss M. Alice Gallagher, R. N.,

executive secretary of the Norfolk County Public Health Association. A corner of the Norfolk County agricultural tent was set aside and a child-weighing and measuring equipment was installed. There was no advertising, no contest and no prizes were offered, but the mothers quickly sensed the meaning of the work, and in the two days 202 children were weighed and measured. These ranged from babies of seven weeks to school children of 18 years. The results were very interesting, for of the entire group of country children, one in every four was under the proper weight for the height, betokening a degree of malnutrition, while a number of the little ones were more than seven to ten per cent. underweight. Incidentally, Miss Gallagher talked with the parents, and in behalf of her association distributed little pamphlets filled with health facts. It was a revelation to the parents and constituted a bit of educational work such as the association is prepared to do. The baby-weighing scales, which were purchased with money secured through the sale of Christmas seals last winter, were presented to the Weymouth Health Station, so that they may be of permanent benefit to the health of the children of the town.

THE WEYMOUTH HOSPITAL.—This hospital, which was made possible by a drive for funds, is located in South Weymouth, Massachusetts, and will meet the desires of residents and physicians of that region.

The hospital is beautifully located and consists of the remodeled house of the late Albert Tirrell, who was a successful manufacturer in Weymouth. The drive netted \$21,405.75. The cost of changing the building and supplying the equipment amounted to \$7,791.17. The hospital was opened May 22, 1922, and the trustees have reported for two months, showing earnings of \$2,526.82, and expense account of \$1,635.21. Fifty-eight patients have been treated. The majority of the cases have been surgical.

Aug. 30, 1922.

Mr. Editor:

In re Weymouth Hospital; there are 20 beds, operating room, delivery room and nursery. Miss Minnie M. Shofield is now Acting Superintendent. The Hospital expects to maintain a training school when it gets well under way, probably next year.

Yours very truly,

JOHN C. FRASER.

Miscellany.

NARCOTIC DRUG INVESTIGATION.

THE following statements are found in the extension of remarks in The House of Representatives by Hon. Lester D. Volk:

"In House Resolution No. 258 and in an address before this body on Friday, January 13, 1922, I called specific attention to rules and regulations issued by the Internal Revenue Department interpreting the Harrison Act, and having the force and effect of law,—a document as extraordinary as ever issued by this or any other Government in its presumptuous assumption of authority and ruthless disregard of facts and experience.

I refer to the rulings promulgated October 19, 1921, by the office of the Federal Prohibition Commission, over the signature of R. A. Haynes, Prohibition Commissioner, and D. H. Blair, Commissioner of Internal Revenue.

This ruling, in effect, disposes of a medical and scientific problem relating to the handling of narcotic-drug addicts by eliminating the physician and scientist and turning the entire matter over to Federal police, district attorneys, and favored sanitarium proprietors and underworld peddlers, who have reaped a golden harvest from their nefarious and illicit traffic.

Without any foundation in proven medical knowledge or experience, this ruling asserts that medical authorities agree that addicts may not be treated unless confined within prison or sanitarium walls and that 'this consensus of medical opinion' is used by the Revenue Department as a basis for the policies of the prohibition commissioner.

In the early stages of the discussion of this problem in this House I received a letter from the Commissioner of Internal Revenue, written in response to my request asking to know upon whose authority the remarkable ruling just cited was promulgated. The reply stated that medical and other experts attached to the Treasury Department decided these questions.

The only other explanation vouchsafed was contained in the language of the regulation to which I have referred, which says:

The following resolution, passed by the council of health and public education of the American Medical Association at its (the council) meeting on November 14, 1920, is pertinent in determining the period over which narcotic treatment should be extended in purely addiction cases.

Be it resolved, That the council of health and public education of the American Medical Association indorses the principle expressed in the California law, section 812, which forbids the use of opium and its derivatives in the withdrawal treatment of those addicted to the use of drugs for a period of more than 30 days after the commencement of the withdrawal treatment.

The American Medical Association may be stated to be the very bedrock of medical opinion in this Nation. It is comprised of the best brain and talent within a noble profession. It has in its membership about 90,000 of the physicians in the United States. It is bound by a code of ethics which has gone further than any other

agency to place the practice of medicine upon the highest pinnacle and plane.

These men and this great institution are unimpeachable. Their integrity is undoubted. Their voice carries with it the weight of a professional body upon which the halt and the lame, the ill and well, must depend for very life itself. And when they speak by resolution we all may listen in full confidence that we are receiving the pure thought of medical wisdom and the real consensus of medical opinion.

AMERICAN MEDICAL ASSOCIATION REPUDIATES ACT OF ITS COUNCIL, ON ADDICTION.

It is of momentous importance, therefore, that the American Medical Association in solemn convention assembled should have arisen in its might and repudiated the minority findings of this so-called council, a group of five men out of this great body,—which minority findings they have dared to set forth, and officials of these United States have accepted, as the solemn opinion of all the medical fraternity.

This repudiation was not the action of a minority committee in the association but resolutions openly introduced and adopted by the vote of the house of delegates of the American Medical Association, representing 90,000 physicians, who had been acquainted with the use made of their organization by the Internal Revenue Department to bolster up unsound policies.

The house of delegates of the American Medical Association also knew to a man this House Resolution No. 258, which specifically described the connivance of Government officials responsible for the Prohibition Commissioner's ruling of October 19, 1921, and of members of the medical profession behind the findings of the council of health and public education of the American Medical Association, as a conspiracy to drive narcotic drug addicts into established sanatoria purporting to treat narcotic drug addiction. (See CONGRESSIONAL RECORD, 67th Cong., 2d sess., pp. 1335-1340, January 12, 1922.)

With this knowledge at hand, the house of delegates of the American Medical Association, representing a true consensus of opinion in general medical practice, voted on May 23, 1922, unanimous adoption of the following resolution, to be presented to this House:

Be it resolved, That the house of delegates of the American Medical Association approves House Resolution No. 258, providing for a select committee of 15 to inquire into the subject of narcotic conditions in the United States.

And so forth. This resolution is a consensus of medical opinion, which neither this House nor the Internal Revenue Commissioner nor the Prohibition Commissioner can overlook or ignore. Nor does it stand alone as an expression of medical thought upon the subject of narcotic addiction and narcotic regulations."

The resolution of the American Therapeutic Society is quoted as follows:

"Be it resolved, That this society indorse the resolution introduced by the Hon. Lester D. Volk, to the end that a careful and scientific investigation of the entire narcotic situation may be had so that both the public and the physician may be benefited thereby."

He then cites endorsement of his resolution by the American Public Health Association and the State Medical Society of North Carolina. His conception of the present narcotic drug situation is expressed in the following language:

"The honest are being persecuted. The innocent are being hounded and harassed and exploited. The sick are being denied care and treatment. The quack and the charlatan and the specific cure promoter are thriving upon their false promises and the hopes and gullibilities of the desperate.

Administration is being perverted and corrupted. Ignorant youth, untought and uneducated in facts and truth, spurred on and his curiosity aroused by morbid and sensational presentation from irresponsible origins, is being drawn into the snares planted by the harpies of human woe and creators of human suffering—agents of the rapidly increasing criminal underworld traffickers and smugglers and peddlers.

The scientific and clinical work and research of men who have made an honest and able study of addiction is being ignored and blocked from recognition by propagandized unscientific and incompetent 'formularizations.'

From everywhere come increasing records of aggravation of the narcotic situation and of smuggling and peddling and connivance in it of administrative officials, the logical and inevitable outcome of a situation created by ignorance and propagandized misrepresentation and suppression of education and true information.

The time has come when the Federal Government must stand aside in scientific matters involving honest professional judgment and permit medical men to practice their profession unhampered by lay administrative dictation. The yardstick of rule and regulation must be discarded for the truer measure of 'good faith' based upon scientific medical teachings.

Shed upon this situation the light of truth, and all of the truth, and it will become possible of solution and checking and control. In no other way can this be done.

Make public and widespread all that is known or available upon this subject so that administrative officials can not avoid or evade facts and real issues and conditions and the public press can not be manipulated into sensational hysteria-creating advertising of selected cases of vice and degeneracy, to the neglect of the needs of the vast majority of the honest and deserving.

When the awakening and arousing and final expression of real 'consensus of scientific opin-

ion,' as expressed in the unqualified indorsements of House Resolution 258, there can be no further excuse for continued persistence in domination over administration and administrative power and action of the fallacies now openly repudiated.

It rests now with the only unbiased, competent body which can openly and publicly and with widest recognition take up and seriously consider the material and evidence in this narcotic situation and compel its universal recognition—the Congress of the United States."

If there are any criticisms of Hon. Lester D. Volk's resolution they should be made public. If his contentions are sound, the medical profession should be active in support of his efforts.

THE ROYAL SOCIETY OF MEDICINE.

ON the occasion of the annual dinner of the Royal Society of Medicine, presided over by Sir John Bland-Sutton, the Jenner Memorial Medal (awarded to persons whose work has been prominent in the prevention and control of epidemic disease) was presented to Dr. John C. McVail, LL.D. In making the presentation the President stated that vaccination rested today on a surer basis than ever before, and much of that was due to Dr. McVail's work. He believed that Dr. McVail was the first person north of the Tweed to receive that honour.

We have pleasure in joining in the chorus of congratulation to Dr. McVail, and we are glad to recognise that his unremitting labours of the past fifty years have been so fittingly rewarded.—*Glasgow Medical Journal*.

EMPLOYEES MAY SELECT PHYSICIAN.

NOT BOUND TO ACCEPT DOCTOR RECOMMENDED BY EMPLOYERS.

THE Franklin District Medical Society at its July meeting took action in the matter of industrial concerns which hand their employees printed cards telling them to employ certain physicians when they are injured. It was voted to send communications to the newspapers, advising industrial employees of their right to employ any physician they choose. The appended communication is the result of that vote.

To the Editor of *The Recorder*:

Owing to the fact that some of our industrial plants see fit to hand printed cards to injured employees, requesting them to go to certain physicians, the Secretary of the Franklin District Medical Society was instructed at the July meeting of the Society to insert in the Greenfield papers a notice to the public informing them of their privilege to employ any physician they themselves may choose for such treat-

ment, regardless of any effort on the part of their employer to influence them otherwise.

"That portion of the Workmen's Compensation Act (General Laws, Chapter 152, Section 30) pertaining to such free choice of physicians follows:

"The employee may select a physician other than the one provided by the insurer; and in case he shall be treated by a physician of his own selection, or where, in case of emergency or for other justifiable cause, a physician other than the one provided by the insurer is called in to treat the injured employee, the reasonable cost of his services shall be paid by the insurer, subject to the approval of the department."

Yours very truly,

CHAS. MOLINE, M.D.,

Sec'y Franklin Dist. Med. Society,"
Sunderland, Mass., Aug. 2, 1922.

—*The Greenfield Recorder.*

EXPOSURE OF THE PROPRIETARY MEDICINE INDUSTRY.

HEARST'S *International* proposes to issue a series of articles setting forth that "The patent medicine of the future is the one that will be advertised to doctors." The author of these papers is Paul H. DeKruif, who is lauded as a "brilliant" worker in laboratory investigation and, according to the prospectus, should be regarded as a great leader. Not having the honor of knowing the writer of these articles, information was sought by letter to the American Medical Association.

The reply is submitted.

Chicago, August 31, 1922.

The Boston Medical and Surgical Journal:

Replying to your letter of August 29, our records show that a "Paul H. DeKruif" was born in Zeeland, Michigan, in 1890, and received his pre-medical education at the University of Michigan. He is also reported to have attended the University of Michigan Medical School during the sessions 1910-1911, 1911-1912 and 1917-1918, but we do not have any record of his graduation or licensure. According to our reports his home address is Zeeland, Michigan. This is all the information we have at this office concerning him.

Yours very truly,

AMERICAN MEDICAL ASSOCIATION.

Obituaries.

HAROLD CLARENCE ERNST, M.D.

Dr. Harold C. Ernst died at the Jordan Hospital, Plymouth, September 7, 1922, where he had been taken a short time previously for an operation, having been stricken while on the way to Boston from his summer home at Manomet. Dr. Ernst was born at Cincinnati, Ohio,

July 31, 1856, the son of Andrew and Sarah H. Otis Ernst. His brothers were the late George A. O. Ernst, a prominent Boston lawyer, and Major-General Oswald H. Ernst, U. S. A., retired, now of Washington, D. C.

Dr. Ernst was fitted for college in Boston, graduating at Harvard in the class of 1876. He was pitcher on the celebrated Harvard baseball nines, J. A. Tyng being the catcher, the battery being the chief factor in winning several series with Yale. Ernst had a tall, commanding presence which graced not only the pitcher's plate but the army uniform during the World War and impressed the committees of the Legislature when he appeared before them in opposition to antivaccination or other harmful measures. After taking his M.D. at Harvard in 1880 he became house officer at the Rhode Island Hospital, settling in Jamaica Plain in practice in 1881 and joining the state medical society. In 1884 Harvard gave him an A.M. Bacteriology attracted him from the first; he entered the Harvard laboratory and in 1885 was appointed demonstrator of bacteriology, a position he held until 1889 when he was made instructor. In 1891 his title was assistant professor and in 1895 professor of bacteriology, continuing in the office until his death. He taught a generation of students. A pioneer organizer of a department of bacteriology in a medical school, he induced the city of Boston to establish a bacteriological laboratory in the early days, to prosecute work in the detection and prevention of diphtheria. At one time he was asked to make a visit with the staff of the Children's Hospital in order to bring the clinical side of medicine into touch with the laboratory.

In 1896 he wrote "Infectiousness of Milk;" in 1898 "Infection and Immunity;" in 1902 "Animal Experimentation," besides many articles in scientific and medical periodicals during his career. At one of his last appearances in public he gave a talk on "Immunity" at the annual meeting of the Boston Medical Library, January 10, 1922.

In the spring of 1906 Dr. Ernst displayed his great executive ability as a member of the committee which arranged for the dedication of the new buildings of the Harvard Medical School on Longwood Avenue, and he edited a history of the school; in the fall of that year he was appointed a member of the new standing committee on Medical Education of the Massachusetts Medical Society. This important committee was organized at the instance of the American Medical Association. Dr. Ernst remained the efficient chairman until 1919, it having been combined with the committee on medical diplomas when the by-laws were revised in 1913. After the American Medical Association began its series of February conferences on medical education in Chicago Dr. Ernst generally attended, bringing home reports to the Council; he devoted much time to the duties of his office and waged a continuous fight for better registration laws

in the Commonwealth, appearing frequently with persuasive words at the State House.

In 1896 he became editor of the *Journal of Medical Research*, which he conducted with success until his death. He was a fellow of the American Academy of Arts and Sciences, on which he served as a counselor; a member of the Association of American Pathologists and for eight years its president; a member of the Association of American Physicians, of the American Society of Naturalists and of the Boston Society of Medical Sciences, acting as president of the last named organization for ten years.

Dr. Ernst is survived by his wife, who was Ellen Lunt Frothingham of Boston, a sister of the Rev. Paul Revere Frothingham, Congressman Louis Frothingham and Dr. Langdon Frothingham. They had no children.

His social affiliations included membership in the St. Botolph, Country, Old Colony, Plymouth, Tennis and Racquet clubs, and the Thursday Evening Club, of which he had been president.

Representing to the public in a dignified way the higher aims of medicine, his taking away leaves in the community a place that will be hard to fill.

WILLIAM STEWART HALSTED, M.D.

Death has claimed the second of the Johns Hopkins Hospital triumvirate, painted by John Singer Sargent,—the surgeon William S. Halsted. Dr. Osler passed to the great beyond in 1919. Dr. Kelly, we are glad to say, is still with us and actively at work. Dr. Halsted was born in New York, September 25, 1852, and died in Baltimore, September 7, 1922, therefore being in his seventieth year. He was a graduate of Yale in the class of 1874, and of the College of Physicians and Surgeons, Columbia, in 1877. Yale gave him an LL.D. in 1904, and he had an honorary F.R.C.S. from England in 1900, and one from Edinburgh in 1905. His medical training was in the city of New York where he served as attending physician to Charity Hospital, 1881–83; attending surgeon to Bellevue and Presbyterian Hospitals, 1885–87; associate surgeon Roosevelt Hospital and surgeon-in-chief, outpatient department, 1881–87; surgeon-in-chief Emigrants' Hospital, 1881–84, and surgeon-in-chief to the Johns Hopkins Hospital, Baltimore, since 1889; also professor of surgery there.

He was the author of many papers on surgery, pathology and physiology, was a member of the National Academy of Sciences, an associate fellow of the American Academy of Arts and Sciences, a member of the American Surgical Association, a corresponding member of the Harveian Society of London and of the Société de Chirurgie de Paris and many other societies. He was a man of international reputation.

HERBERT JOHN KEENAN, M.D.

Dr. Herbert J. Keenan died suddenly of heart disease at his home in South Boston, September 7, 1922, at the age of fifty-one. He was born in

that part of the city February 10, 1871, attended the Lawrence grammar school and English high school and Harvard Medical School where he received his M.D. in 1894. Since then he had practised medicine in South Boston. He did work for the police department, served on the School Committee in 1903–04–05, was medical examiner for several fraternal organizations and life insurance companies and held membership in the Boston Lodge of Elks, South Boston Council, Knights of Columbus, Charitable Irish Society, Ninth Regiment Associate Members' Association, South Boston Citizens' Association, South Boston Medical Society and the Harvard Club of Boston. In his early practice Dr. Keenan made a specialty of children's diseases. He had a splendid physique, and was a constant attendant at the L-street bathhouse and appeared to be in the best of health until shortly before the end.

He is survived by his widow, Mrs. Nellie Donovan Keenan.

EDWARD ANTHONY SPITZKA, M.D.

Dr. Edward Anthony Spitzka, noted anatomist and criminologist of New York, died at his home in Mt. Vernon, N. Y., September 4, 1922, at the age of forty-six. He was the son of Edward Charles Spitzka, a pioneer neurologist and psychiatrist of New York, was educated at the College of the City of New York, taking his M.D. at the College of Physicians and Surgeons in that city in 1902. He was professor of general anatomy at Jefferson Medical College, 1906–1914. Dr. Spitzka performed the autopsy and examined the brain of Czolgosz, the assassin of President McKinley. His chief contribution to medical literature was his editorship of the 18th American edition of Gray's Anatomy. During the World War he saw service in France in the Medical Corps, ending with the rank of lieutenant-colonel.

He is survived by his widow, who was Alice Eberspacher of New York.

GEORGE MILBRY GOULD, M.D.

AN important medical writer, one who understood words and their uses, providing the profession with medical dictionaries, also an editor of note, has passed to his long rest. Dr. George M. Gould died at his home in Atlantic City, N. J., August 8, 1922, after a brief illness from heart disease, at the age of seventy-three.

The son of George Thomas and Eliza A. Lapham Gould, he was born at Auburn, Me., November 8, 1848. During the Civil War he served as a drummer boy with the 63d Ohio Volunteers when only fourteen years old; enlisting in the 141st Ohio Volunteers in 1864 he finished the war with that regiment. The Ohio Wesleyan University gave him an A.B. in 1873 and an A.M. in 1892. He studied at the Harvard Divinity School in 1873 and 1874, graduating in the latter year, but without a degree, as had

been the rule before 1870 and the general custom until 1874. For the next ten years he was a preacher, finally taking up the study of medicine at the Jefferson Medical College in Philadelphia and graduating in 1888 when he was forty years old. He began practice in Philadelphia at once, making a specialty of ophthalmology and serving as ophthalmologist at the Philadelphia Almshouse from 1892 and 1894.

Dr. Gould was editor of the *Medical News*, 1891-1895; *Philadelphia Medical Journal*, 1898-1900; *American Medicine*, 1901-1906. While still in the medical school he collaborated in the preparation of a compend of diseases of the eye, published in 1886-1888; he was a fellow of the American Ophthalmological Society; late in life he wrote a series of papers on the effect of eye strain on some noted literary characters such as Francis Parkman and Thomas Carlyle, that excited considerable interest. His first medical dictionary, "Students' Medical Dictionary," appeared in 1890, the eleventh edition of which was published in 1900. The "New Medical Dictionary" ran through ten editions and the "Pocket Medical Dictionary" came out many times between 1892 and 1913, while the "Practitioners' Medical Dictionary" had a large sale from 1906 to 1917. Dr. Gould was author of "Illustrated Dictionary of Medicine, Biology and Allied Sciences," 1894-1913; "American Year Book of Medicine and Surgery," 1896-1903; "Borderland Studies," 2 vols., 1896-1906; "Suggestions to Medical Writers," 1900; "Encyclopedia of Medicine and Surgery," 1900-1913; "Anomalies and Curiosities of Medicine" (in collaboration), 1901; "Biographic Clinics," 6 vols., 1903-1909; "History of Jefferson College," 2 vols., 1904; "Righthandedness and Lefthandedness, etc.," 1908; "The Infinite Presence," 1910; "Life and Letters of Edmund Clarence Stedman" (in collaboration), 1911.

Dr. Gould was married twice, first to Harriet Fletcher Cartwright, of Pomeroy, Ohio, October 15, 1876, and second to Laura Stedman, October 2, 1917.

Men like Dr. Gould are scarce in the ranks of the medical profession. His training as a clergyman gave him facility in expressing thoughts in words; his long study in language made possible the dictionaries; editing three leading periodicals gave practice in writing, an experience which was epitomized in his "Suggestions to Medical Writers;" he performed a noteworthy service in improving the quality of the English used by medical men. The profession is grateful.

RECENT DEATHS.

Dr. George Cook, former president of the New Hampshire Medical Society, and chairman of the New Hampshire Board of Registration in Medicine, died at his home in Concord, September 1, 1922, at the age of seventy-three.

Dr. Cook was born at Dover, N. H., November 16, 1848, and was graduated at Dartmouth Medical School

in 1869, joining the state medical society in that year. He early became identified with the New Hampshire National Guard and served as major and surgeon of the First Division, Second Army Corps, U. S. V., in the Spanish War. During the World War he was chairman of the State Selective Service Board, being too old to enter the active service.

Dr. Cook organized the Alpha Kappa Kappa fraternity in the Dartmouth Medical School in 1890 and since then traveled about extensively organizing similar chapters—forty-eight in all—holding the office of grand primarius for the past ten years.

He held membership in the American Medical Association, the Historical Society, the Masons, the Odd Fellows and the Sons of Veterans. He had served as city physician, pension examiner, and as a member of the consulting staff of the Margaret Pillsbury Hospital in Concord.

A brother and two sisters survive him. The funeral services were held in St. Paul's Episcopal Church, of which he had long been a vestryman.

Mrs. ELIZABETH J. COLLINS, cataloguer-in-chief of the Boston Medical Library for forty-two years, has died of heart disease, after being in failing health for two years. The end came September first at three o'clock in the morning.

Mrs. Collins came to the Library five years after it was founded, having been trained at the Boston Public Library under Justin Winsor. Her conscientious and skilled labor has added much to the advancement of the institution through all these years. She will be missed by a large circle of members and friends.

Correspondence.

BIOLOGIC PRODUCTS.

Mr. Editor:

We should greatly appreciate your aid in bringing to the attention of members of boards of health and of physicians the great necessity of using biologic products before their expiration date. During the present summer two instances have come to our notice, in one of which a physician during the present month used a lot of our smallpox vaccine virus which was more than a year old; and in a second case a physician reported a failure to secure a "take" after using our vaccine virus bearing the expiration date May 30, 1922. We are constantly telling boards of health to carry stocks of biologic products sufficient to meet only a one month's demand, and in all our leaflets accompanying our biological products we ask physicians to limit their orders to ten-day periods. We request physicians to keep a record of the lot number on each package and to return any packages which have not been used before the expiration date stamped on the label. A short notice or an editorial would, we feel, be helpful in avoiding just such unsatisfactory results as I have mentioned.

Yours very truly,

BENJAMIN WHITE, Director.

THE STING OF THE SEA NETTLE.

Mr. Editor:

Perhaps this might interest you, if true. A letter from New Hampshire states: "The Boston papers, last week, spoke of the Jelly-Fish as rendering our Down-East swimming contestants unable to cross the English Channel."

Yours sincerely,

DOUGLAS H. STEWART, M.D.

128 W. 86th St., New York City.

THE TREATMENT OF DEHYDRATION IN INFANTS.
By OSCAR M. SCHLOSS, M.D., BOSTON.

WHEN one considers that approximately three-quarters of the infant organism is composed of water, it is quite evident that the subject of water metabolism in infancy is one of importance. Each ounce of weight gained in a normal manner means the gain of approximately three-fourths ounce of water. Moreover, every metabolic process in the organism is dependent on the presence of a proper amount and a proper distribution of water: the transfer of nutriment and waste products, the secretion of digestive juices, the secretion of urine, are important examples. The nicety with which the water in the organism is adjusted is regulated by a remarkable mechanism. It is due to no accident that the normal water content of the blood and tissues is regulated to a fraction of a per cent. Concerning the nature and exact processes concerned in this regulation, only a few fragmentary facts are known. For this reason it would seem of little profit to discuss the subject from such an aspect. More, however, is known of the disturbances caused by a deficit of water

in the infant organism, and fortunately something is known of the means of combating it. The rapid loss of water in infants causes a series of serious symptoms and striking perversions of function. These are known to all of you. Many of the symptoms of so-called "Cholera Infantum" or "Acute Intestinal Intoxication" can be attributed to the dehydration of the blood and tissues. This condition usually follows severe or prolonged diarrhea, but is often caused by lessened intake of water, due to refusal of fluid or persistent vomiting. In some cases all conditions are operative.

I have mentioned the nicety to which the water content of the body is adjusted. This adjustment is probably dependent to a large degree on the presence in some tissues of large amounts of loosely bound water which can be readily mobilized. Our interest in these water storehouses arises from the fact that they serve to keep constant the water content of the blood and that the serious symptoms of dehydration usually occur only when the blood shows a loss of water and increased concentration. In other words, it seems probable that in conditions of abnormal water loss the available fluid is drawn first from the tissues until this supply is depleted. After this, water is lost from the blood and serious symptoms occur. From the evidence available it would seem that the importance of tissues in the storage of water is relatively as follows: (1) the skin and subcutaneous tissue, (2) the muscles, and (3) the liver. This is indicated by the results of Freund Steinitz, and others. In this connection it is of great in-

terest and importance that the earliest clinical sign of water deficit is the loss of skin elasticity. This familiar sign is very definite and easy to demonstrate. When one pinches up a fold of normal skin it has a resistant or elastic feel, and if released suddenly it immediately returns to its former place. If the skin has lost water it does not have the normal elastic feel but can be described as plastic or putty-like, and when released suddenly it returns slowly to its former position. This sign varies in intensity, depending on the degree of water loss. It indicates the fact that the organism is laboring under a deficit of water which if not rectified will lead to serious symptoms.

When the degree of dehydration is marked there is a loss of water from the blood. An increase in the blood concentration in these cases has been shown by Reiss, Salga, Schloss and Marriott and Perkins. It would seem that the loss of fluid from the blood is the cardinal symptom. The various other profound changes are secondary to and dependent on this. Oliguria is constant and anuria frequent and the kidney is prevented from exercising its usual rôle in regulating the acid base balance of the body. Due to this, severe acidosis results. (Howland and Marriott, Schloss and Stetson.) Upon the same cause is probably dependent the retention of nitrogenous waste products in the blood. (Minsk & Sauer, Schloss.)

In 1918 I reported a study of cases of so-called intestinal intoxication which showed a marked increase in the non-protein nitrogen of the blood. It seemed that the symptoms were not dissimilar to those of uraemia, caused as in uraemia by defective kidney elimination, but due to the depletion of water and to resulting direct and remote alterations in the blood and circulation, rather than to pathological renal changes. It did not seem probable that the high non-protein nitrogen of the blood was due directly to the increase in blood concentration but indirectly to it through interference with the secretion of urine. General changes in the circulation have been demonstrated by Marriott and his co-workers. They found a diminished blood volume, diminished volume flow of blood, low blood pressure and capillary stasis. Marriott has called attention to the similarity of this condition to surgical shock. It would seem that all of these disturbances are due to the loss of fluid from the blood.

These in brief are the pathological changes caused in infants by a marked depletion of the body water, and upon these changes are dependent many of the severe symptoms which accompany the condition.

From a therapeutic standpoint the indication in all cases is to restore the water balance of the body to normal. The means necessary to do this depends on the degree to which the depletion has progressed and the severity of the symptoms. The necessity of giving large

amounts of fluid to such cases has been recognized for many years. Large amounts of fluid by mouth is a useful procedure but is adequate only if the dehydration is mild, and in the absence of severe diarrhea and vomiting. Subcutaneous injections of isotonic salt solution have been a regular part of the treatment for a long time, and in the milder cases may be sufficient to restore a normal water balance, especially if the diarrhea has ceased or is slight. A useful addition to the methods of giving fluid parenterally is the intraperitoneal method introduced by Blackfan and Maxey. The efficacy of the subcutaneous and intraperitoneal methods is dependent largely on the degree of water loss and the severity of symptoms. Only a limited amount of fluid can be given by either method at one time; if the blood concentration is greatly increased and the resulting symptoms severe, the patient often succumbs before the water deficit can be restored sufficiently to influence the blood concentration. For this reason additional treatment is necessary in the severer cases. Since the cardinal symptom of severe dehydration and the cause of the severe disturbances is the increased blood concentration, any measure to be of most value should be one to influence this very quickly. It had been found that intravenous injection of isotonic solutions had only a very transitory influence on the blood concentration, and practically none on the symptoms. The blood showed some dilution for about fifteen minutes after the injection, but the concentration quickly returned to its previous level. This experience was quite in accord with the observations on animals by Underhill, Mendel and others. It then seemed advisable to try the effect of intravenous injection of hypertonic solutions following the injection either subcutaneously or intraperitoneally of an isotonic solution, the object of the hypertonic solution being to increase the blood volume by its osmotic pressure. Two types of solutions were tried—hypertonic salt (sodium chloride) solution and hypertonic solutions of glucose. Both had the effect of reducing the concentration of the blood to a marked degree, which effect persisted from two to four hours. Both promoted the secretion of urine, but in this regard the glucose was much more effective. Moreover, it was found that the glucose given intravenously was retained to a large degree, only a small amount appearing in the urine. Since most of these patients are greatly in need of food the caloric value of the glucose is not negligible.

The treatment as applied to the cases of severe dehydration is as follows: the patient is given a subcutaneous or intraperitoneal injection of saline or Ringer's solution, and within one hour an intravenous injection of a 10% glucose solution. The amount of isotonic saline or Ringer's solution to be given varies with the size of the infant, the usual amounts by subcutaneous injection varying from 80 to 300 c.c., by

intraperitoneal injection from 125 to 400 c.c. Twenty c.c. of 10% glucose solution per kilo of body weight is the amount which is usually given. It is important that the glucose be given within a short time after the saline. It is of greatest importance, especially if the dehydration is at all marked, that an isotonic solution be given before the glucose; otherwise the treatment does no good and may do harm. An important precaution in the preparation of the glucose solution is that it should be absolutely clear. A precipitate, even in small amount, may produce marked and even serious reactions.

The treatment outlined may be repeated in five to six hours if necessary, the necessity to be judged by the condition of the skin and the general symptoms. Usually two or three injections of the glucose solution are sufficient. After improvement is pronounced the glucose injections may be omitted and occasional subcutaneous injections of normal saline are often sufficient to maintain the normal water content of the organism.

The effect of this plan of giving fluid is usually pronounced. There is an early secretion of urine, the condition of the skin becomes normal and the general symptoms rapidly disappear. Due to the removal of its cause, the acidosis is corrected, so that the use of alkali is entirely unnecessary.

In principle, what I have outlined presents little that is original. It is offered merely as a method of combating dehydration in infants that has proved extremely efficacious.

DISCUSSION.

T. M. CARPENTER, PH.D., Boston: Dr. Schloss has not considered the question of the mathematical side of the water balance. I think it would be interesting to know what the absolute amount of change in percentage was in the total water content of infants as compared with adults. Rubner has stated that with adults a reduction of ten per cent. of the water content results in serious disturbances. The determination of the water balance technically is extraordinarily difficult, and probably for that reason very little work in comparison with other metabolic factors has been done. In addition to that the familiar existence of water all around us has led us to say "what is the use of studying water balance?"

It seems to me that another interesting fact in Dr. Schloss' paper is the effect of the different methods of introduction, of either hypertonic solutions, water solutions, or glucose solutions. For a number of years I have been interested in the metabolism with reference to the method of introduction, and I have been studying the introduction of solutions by various routes, the effect of rectal introduction of sugars, the distribution of alcohol when inhaled and the metabolism of substances when introduced by mouth. I would be interested to know what route is most efficient and whether one can supplement the other.

DR. OSCAR M. SCHLOSS, Boston (closing): In regard to Dr. Carpenter's question, the route by which water is given is of some importance. Most of these infants are suffering from severe diarrhoea or from vomiting. In the presence of vomiting, giving water by mouth is impossible. The water loss through the diarrhoeal stools is so great that it is almost impossible to give

these babies sufficient water by mouth to replace the amount lost, so that this method isn't of any particular value. Infants retain fluids given by rectum poorly, the tube usually causing irritation, so that it is possible to give only a relatively insignificant amount in this way, so that we are restricted to the three methods I have mentioned—intravenously, subcutaneously and intraperitoneally.

One thing I didn't mention was the question of intraperitoneal injection. The giving of fluid intraperitoneally has the advantage of permitting the use of larger amounts of fluid than either of the other methods. It often causes a mild disturbance. It causes a sterile inflammation with exudate of cells, causing no apparent harm except as evidenced by abdominal distention. In most instances it should not be repeated under 24 hours.

With regard to our general knowledge of the water balance in infants, little is known. There have been no accurate determinations due to the difficulties which Dr. Carpenter had in mind. That is, in determining with accuracy the amount of water lost in various ways.

THE PEDIATRIST'S OPPORTUNITY.

By EUGENE R. KELLEY, M.D., BOSTON.

CHILD hygiene is largely the outgrowth of the pediatricist's vision, enthusiasm and faith. Child hygiene as a result of its meteoric expansion in the past fifteen years has in many ways grown away from the pediatricists and the medical profession. Child hygiene now involves many fields of social endeavor which have hitherto been remote from the purview of the medical mind, as, for example, the subject of supervised play. Child hygiene now numbers among its exponents, and is yearly bringing into greater public prominence members of professions and specialized groups within professions, the scenes of whose original training are far removed from the anatomical laboratory or the clinical amphitheatre. Their ways are not our ways, their language is not our language, their thoughts are not our thoughts. Yet, as I will later attempt to illustrate, this subject is essentially one that must rest upon medical and hygienic scientific principles for its bed-rock foundation if its present glowing promise is to be fulfilled.

In the world of scientific medicine the group that by training, aptitude, previous experience and natural association of every-day work comes into most direct contact with the problems of child hygiene is the children's specialist, the pediatricist. Hence, as I see it, child hygiene may be most truthfully and accurately characterized as the pediatricist's opportunity. But as I look back upon the impetuous sweep of the rising tide of popular interest in this subject during the years just passed the question occurs if the title ought not to go a word further and read, "The pediatricist's *vanishing* opportunity."

Perhaps the most striking recent feature in the child hygiene movement has been its constant expansion. There is but little exaggeration in saying that infant feeding was almost synonymous with child hygiene in the begin-

ning of the modern development of the subject. The possibilities of school hygiene had been recognized by pioneers in the ranks of public health and public education three generations ago. Here and there dentists were beginning to emphasize the significance of oral hygiene; public health nursing in its modern form was making itself known about the same time, but in my own experience as a medical student, I can testify that "modified milk" summed up about all that was taught inside the medical school in reference to child hygiene; and, broadly speaking, little more than that was actively discussed by any organized groups outside the medical school.

It sometimes seems to the medical health administrator that the medical mind still looks fixedly at the magic formulae designed to make cows' milk safe for infancy almost to the exclusion of real comprehension of the wide ramifications of modern child hygiene as a specialized division of public health and public welfare. Sometimes it seems as if the procession has passed him by and instead of the pediatricist being in the front rank of the movement we see there public health nurses, dentists, dental hygienists, nutrition workers, physical educators, social service workers, chemists, bacteriologists and (a slightly pathetic figure in this connection) the medically trained professional health official who never enjoyed the advantages of any special training or experience in pediatrics. This statement, of course, does not include the small group of pediatricists who have perseveringly fostered the infant and child hygiene movement from its inception: brought it through its early years of financial inanition; overcome those acute organization exanthemata which afflict the childhood of all our voluntary health movements as inevitably as do measles their little human patients, and who now can see with satisfaction the prominent place child hygiene has come to assume in our national life, with countless numbers of enthusiastic laity who are today demanding greater attention to child hygiene all over the land. But when the health administrator surveys this rapidly growing army of child hygiene enthusiasts, and looks about for the pediatricists to act as the commissioned officers and drill sergeants of this new army, he doesn't find them—at least not in any such numbers as they should be found.

This is a serious situation. The child hygiene movement needs the pediatricist. Increasingly, I think, the pediatricist of the future will need the child hygiene movement. I cannot but feel that medicine in general and the specialty of pediatrics in particular are failing to measure up to their opportunities in relation to child hygiene, particularly along the lines to which I will now briefly allude:

(1) There is an obvious failure on the part of medical schools to teach the phenomena of the normal in relation to infancy and childhood. The average young medical graduate has

some idea of how to proceed when confronted with a morbidity problem in relation to childhood. He is far more frequently than the proverbial nine times out of ten quite at a loss when consulted for hygienic advice by the mother of the well baby. Yet a refrain that runs throughout all the teaching of the child hygiene movement, a message that is being shouted at American motherhood today by lecture, by pamphlet, by prize school essays, by the daily press, by popular magazines for women, by stereopticon, movie and radio is short, hortatory and emphatic, and runs as follows: *Consult your doctor, and follow his advice before baby gets sick.*

(2) There is another way in which I feel the pediatricist is not measuring up either to his opportunity or his duty in this field. It is simply this. On account of his peculiar training and experience the community has a right to expect him to contribute his advice, time and energy in the child hygiene campaign as a public spirited citizen—not by lending a hand to a biennial two-day weighing and measuring campaign, with its hubbub and frequently misleading results, but by being on the child hygiene job all the time, talking it, urging it, in public and private, by actually practising preventive pediatrics on both a fee and a free basis. The public and all the other workers in the campaign look to the pediatricist as the natural leader *par excellence* of the entire child hygiene movement, and, as I have previously said, it is rather a shock to look about and see how few of our best and busiest pediatricists are really actively engaged in any phase of continuous child hygiene service.

A new federal measure which has been so extensively discussed that it needs no comment here, the so-called Sheppard-Towner Act, has introduced a new and extremely far-reaching factor into the subject of child hygiene in this country. It is not intended to discuss any of the principles involved in this act at this time. I only wish to point out to you how this law has generally stirred up public interest and awakened public opinion as to the potentialities of a comprehensive national child hygiene program, regardless of the existing differences of opinion concerning the soundness of the principles involved in this particular measure.

The people are thinking, talking and eager to learn more about child hygiene. We have notable examples abroad of tremendous interest in this subject awakened during and sustained since the war. Sir George Newman, Chief Medical Officer of the Ministry of Health of England, states the fundamental importance of the subject in three terse sentences: "The health of the mother and child is obviously the primary step in the health of a community. For here is the source of a nation. It is almost true to say that, from a health point of view, what the mothers and children are, the nation is and will be." The thing that strikes a health ad-

ministrator most forcibly in reference to child hygiene when contrasting conditions in this country with those of England is the practically universal acceptance there of the national and local governments' responsibility in the matter.

The following table shows the astonishing rate of growth of the maternal and child hygiene movement in England and Wales in recent years as reflected in the statistics of the number of infant welfare centers, the number of nurse workers, and the infant mortality rate. Unfortunately, the number of full-time and part-time pediatricists and medical child hygienists are not given, but that they are very numerous can be judged from the context.

ENGLAND AND WALES,
Child and Maternal Hygiene.

Year	Health Centers	Non-Medical Workers Number	Infant Mortality Rate
	Number	i.e., Nurses and Nutrition Workers	
1913	No report	No report	108
1914	250	" "	105
1915	400	" "	110
1916	720	" "	91
1917	970	2555	96
1918	1133	3038	97
1919	1412	3074	89
1920	1754	3359	80
1921	1960	Not given	Not given

The degree to which governmental child hygiene directly affects the people of England is epitomized in the statement of Sir George Newman in his last available report that in 1920 "at least one-sixth of all babies born came under the regular supervision of the doctors and nurses of the infant welfare center in addition to a much larger number visited in their own homes. *These are ordinary normal babies.* They are brought for observation and advice, not for treatment. The center is not an outpatient department nor a treatment clinic." In other words, this is nation-wide practice of infant hygiene in contrast to practice of pediatricies as the term has hitherto been understood. I have cited British progress in child hygiene at some length not because I think the system is one that will ever be adopted *en masse* in this country, but because I believe it is a fair picture of the rate of development in child hygiene work which we may anticipate with absolute certainty in the next ten years. This means that medical men must be found to take charge of these clinics and the medical men ought to be, whenever possible, pediatricists trained in preventive pediatricies.

Other factors, of course, have entered into the stimulation of public interest in child hygiene besides the passage of the Sheppard-Towner Act and the example of the English child welfare movement. The increased interest in such

specialized phases of child hygiene as nutrition, dental hygiene, school hygiene and physical education all throw into greater prominence the fact that child hygiene is a migratory national problem and, regardless of the advances along these specialized lines, that in the last analysis it is an indivisible and predominantly medical problem.

Our failings in national physique as revealed by the draft examinations and the newer developments in the great subject of mental hygiene also show that the problems uncovered point back largely to child hygiene as the means by which we can best hope for the correction of these national deficiencies.

What I want to make clear is that this problem is one that calls for highly technically qualified leadership. At the present time there is a very definite tendency towards the development of non-medical leadership in the child hygiene movement in this country, with all the attendant dangers to the cause that such a development entails.

No one recognizes this danger more clearly than the representatives of the two other professions that have been thrust by force of circumstances into positions of leadership in child hygiene—the nursing profession and the as yet but partially formed profession of social work. To a lesser degree nutrition experts and physical educators are also having forced upon them the problem of shaping policies and ways and means of practical procedure in child hygiene. Frequently in the past three years have I heard representatives of these various professions plead for the great need of qualified medical personnel to take the lead in shaping our rapidly, even if largely unconsciously, developing national policy in child hygiene.

Coming to the real crux of this paper, I wish to present the reasons why it seems to me that it is imperative that the specialty of pediatricies should not merely continue, but should greatly extend its past leadership in the development of the child hygiene movement. To fully show what this means it is necessary to face at once a fact that medicine as a profession has always refused to face; viz., that clinical medicine does not to any appreciable degree teach the art of preventive medicine. It does offer, however, considerably more than a bowing acquaintance with the fundamental sciences of preventive medicine or hygiene. Medicine has from time immemorial focused upon the attempt to mitigate the course or prevent disastrous effects of already-established morbid processes. It has had pitifully little to do with endeavoring to prevent morbid processes from beginning, as Sir James Mackenzie has so forcefully pointed out in his revolutionary little book, "The Future of Medicine."

Nevertheless, because the basic knowledge for either curative or preventive medicine must be the same, and because training in clinical

medicine is, in my judgment, unquestionably the best preliminary training yet devised for child hygienists, any other professional group carries heavy handicaps when it assumes, or, as is more commonly the case, is drafted for responsible executive positions involving formulation of policy and methods of procedure directed toward the whole broad field of child hygiene. Here lies what is at once the opportunity and moral duty of pediatrics and the greatest danger our national child hygiene program now faces. I refer to the crying need for pediatricists with vision and training on the preventive side of medicine to assume leadership in this field, and, failing this, the danger of the movement's dissipating much of its present energy and forfeiting much of its present enthusiastic support, as a result of untrained leadership of non-medical individuals. In addition to the relatively small number of physicians with pediatric training needed to be transformed entirely from the old man of clinical medicine into the new man of child hygiene to furnish the full-time teachers and general staff of our army of child hygiene workers, I also put in a strong plea for all pediatricists to engage *actively* in such degree as individual gifts of personality and circumstances of environment may permit in the business of helping to train and guide this growing army of non-medical child hygiene workers.

Among many reasons which could be expanded to great length in support of the statement that a medical background in general and a specialized pediatric background in particular are almost a *sine qua non* in the development of proper perspective in child hygiene, these few may be specially cited. Or it might be more correct, as well as more forceful, to put it the other way round and say that the following roots of the child hygiene problem grow out of a soil which only medical training fits one to cultivate intelligently.

1. A large share of our present-day child hygiene program is still greatly affected, or, in fact, made necessary by conditions handled hitherto through clinical medicine alone. I refer to the great group of child hygiene problems growing out of the acute infections of childhood—sequelae and complications traceable directly back to previous attacks of measles, whooping cough, scarlet fever, meningitis, poliomyelitis, etc.

2. Another group of infections not so exclusively allocated to childhood—in fact, diseases affecting adults equally or more, but which create no small fraction of the problems of the child hygienist—are gonorrhoea, syphilis and tuberculosis.

3. Still another group of morbid conditions which complicate the child hygiene problem, and which call for medical background for their intelligent handling, are those numerous developmental or acquired physical defects of childhood, of which defects of vision and hearing,

adenoids and postural defects are prominent examples.

4. Another great factor in a successful child hygiene program is the ability to recognize and evaluate properly the bearing of nutrition and malnutrition and to apply appropriate measures to all problems relating to the digestive and assimilative capacities of the child. No argument is necessary to show that medical training is indicated here, but much awakening within the profession is still needed to convince both the doctor and the layman that to really cope with the child hygiene problems of this group a medical *plus* training is needed. The *plus* represents real knowledge of the basic sciences of nutrition and food values and an appreciation of the art of child nurture generally.

5. Nor can we for a moment overlook the fact that child hygiene demands a keen appreciation of the fundamental importance of mental hygiene as applied to child life!

To properly comprehend and, as far as may be possible, provide compensating and protective processes for the feeble-minded; to be able to plumb the psychological depths of childhood phobias and incipient childish psychoses; and, in general, to understand the best methods of adjusting the unfolding mentality of the normal and, still more, of the super-normal minded child, is an essential part of the program of child hygiene.

To give the impression that child hygiene should be held as the exclusive preserve of the pediatricist would be grossly unfair to many other professions and specialties doing pioneer and invaluable work in this great field, but to do justice to these groups would too far transcend the limits of your patience and the rules of this section. Suffice it to say that I wish to pay hearty and sincere tribute to them all. More power to them all! The nurse, whether institutional, public health, district, tuberculosis or industrial as to specialty, fills a commanding place in the program. The dentist and dental hygienist, the nutritionist, the research worker, the psychologist, educator and social worker—all have their indispensable part to play; but I hope I have to some degree made clear the fundamental non-substitutable (if there be such a word) position that the child hygiene program reserves for the pediatricist. I trust I also have indicated the growing feeling of dismay with which the health administrators of this country look about them and see the so inadequate response of volunteers from the pediatricist ranks coming forward to fill these positions. The financial reward of the medical child hygienist is very meagre, and the work involves to a large extent the surrender of that complete individual freedom of action which is so dear to the medical heart; but I know of nothing in the whole range of medicine, hygiene, sociology or public service where the opportunities for scientific, lasting, humanity-benefiting service are greater today than in this field of child hygiene.

DISCUSSION.

DR. M. E. CHAMPTION, Boston: Dr. Kelley has given you an outline of what we hope child hygiene will be in the future. I merely want to touch on a few concrete points where the pediatricist can do good at the present moment. There are certain fields which are decidedly open to him at the present time which are not being covered in any adequate way. I suppose that all types of work outside of that carried on by the individual practitioner may be divided into public and private. As a matter of fact, all the public work has grown out of some type of private action. In some places the public action is yet to be undertaken. The City of Boston, I suppose, is a pretty good example of that. The people who control the appropriation of money in the City of Boston have never seemed willing to appropriate enough money to carry on child welfare work. As a result the work that is being carried on in this field is carried on by private agencies. Therefore the pediatricist who works with the private agency has the opportunity of shaping to a certain degree the course of the public agency when it takes over the work.

There are certain types of work which ought to be mentioned. In the first place, there is the administrator in the private agency. He is often the secretary or perhaps the president of the board or serves on some advisory committee. And then there is the man who carries on the clinical work. That man has an important position, for if he is wise, he will start the child hygiene work in such a way that when the community takes it over it is not involved in the complications of "State medicine"—complications which are hard to get rid of once they are fixed on any public agency.

Then there is the other type of worker, the one who is working in the public service and is paid out of municipal funds. There again he may be an administrator, but these administrators are not very common.

I have been much interested in looking over the lists of those in charge of State child hygiene activities in this country. These directors have been generally public health nurses. It must be acknowledged, however, that since the much-criticized Shepard-Towner Act has gone into effect we have seen more physicians going into this field.

Furthermore, there are other opportunities as well. We need investigators, physicians who are qualified to look into the question of infant and maternal mortality, because these figures which Dr. Kelley has put on the board are hard to explain—very hard to explain—particularly the 75.9 per cent. mortality among infants. I wish that we could feel that we knew exactly the reason why we had such a tremendous drop in infant mortality last year. We need trained men to investigate that.

There is an opportunity which I want to stress in closing, which occurs, at present, in 355 cities and towns in Massachusetts: It is in connection with the position of school physician. Some months ago I attended a legislative hearing where somebody said that only the poorest doctors in the town were school physicians. That of course was an unjust statement to make. Nevertheless, many of the best trained men do dodge that job. It is an opportunity for public service, though not for making money, and if we could get physicians throughout the State to feel that there is an opportunity to take charge of our children when they are in a normal state and to keep them in that state and thereby to help the municipalities to do good service, it would do more for child hygiene than anything I know of.

DR. E. H. PLACE, Boston: After hearing this paper of Dr. Kelley's, I can only emphasize a few points which are important. The first that he spoke of was

the absolute necessity for physicians doing work among children to be well grounded as to the normal child. Many of us have graduated from medical school so long ago that we look back and see that very little information was given on the care of the normal child, and many of these problems put up to us by mothers we are unable to answer. It seems to me that that must not happen in the future. It seems to me that the coming generation of physicians must be made to recognize and know the normal child, and that applies to all of us who are now practising.

The child hygiene movement at the present time is going forward very rapidly, and it is obvious that the movement is going still farther, and the only question is—who is going to guide that movement? Unless it is going to be guided by pediatricists, it is going to be guided by people lacking in knowledge and it is going to be guided along lines which are undesirable. So, from every point of view, it seems to be our responsibility to see that it is to be developed upon a sound, medical basis.

DR. ELLA G. STONE, Boston: When Dr. Kelley was speaking, I was thinking of the large number of nurses and social workers engaged in child hygiene activities, mostly women, no doubt, judging from Dr. Kelley's urgent appeal that more medical men enter this field that these women may be properly directed.

It seems to me that here must be an opportunity for women physicians to do their best work. Women have a natural interest in children and do not need the stimulation that men require. The average young man who starts out on his medical career doubtless knows or cares little about children. His natural inclination generally leads him into other lines of medical work. On the other hand, the aspiration of the average normal woman, whether she be a member of the medical profession or any other profession, is to have a home and children of her own to love and care for. The vocation of nursing and caring for children seems foreign to the nature of men. Way back in the dawn of animal life, sex determination ordained that this should follow without any discredit to the male. Let us be wise in time and try to coordinate our child betterment endeavors with adult welfare or all our effort will be worse than useless. We may wake up to find that we have been simply amusing ourselves for profit or caprice in experimenting with plans for the betterment of the status of children only to throw them into the scrap heap when matured.

For the best and highest development women need the soul-satisfying work of caring for children. It is nature's decree—their dominant impulse is maternal. Therefore, in view of woman's natural selection for the purpose of reproduction and care of children, the fitness of encouraging women physicians to enter the child hygiene field seems apparent. I am sure they do very acceptable work.

DR. J. L. MORSE, Boston: I was much surprised by one thing that Dr. Kelley said, and that is that social workers or public health workers would like to get information from doctors. With two exceptions, I have never met a social worker or nurse that desired to get any information from a doctor or be told anything by a doctor.

In speaking of the different classes of people in social work, we have one class that is in it for amusement or because they haven't anything else to do. Then we have another class, that is being paid for it—the social workers and the nurses. No wonder the interest of the social workers is being stimulated! The nurses are also getting paid for their work. No wonder they are interested!—they have a good job. Now the poor doctor is again asked to be the goat,

as all of us now are, to give his time and work for nothing, or if he doesn't give it for nothing, to give it for a salary which is entirely incommensurate with what he could earn in any other way. It may be the doctor's duty to take up this work, as it is his duty to take up a great many other things, but he has got to do it as a duty and look for his recompense in heaven and not on this sphere. That may be one of the reasons why doctors are not interested. They are expected to do it all for nothing.

DR. EUGENE R. KELLEY, Boston (closing): Some of the things brought out in the discussion were very interesting to me. I want in closing to comment on some of the things which Dr. Morse said; but the first thing I want to comment on is that there is a great and growing willingness among well-informed people to pay for prophylactic advice. You would be surprised to know the number of times people in my position, *i. e.*, public health workers, find the truth of that statement. The position of the young clinician that he will not take any money unless he can deliver something directed toward a correction of a morbid process is fundamentally wrong. There is an unlimited opportunity for financial return for the pediatricist practising hygiene on the fee basis, and I don't think it is being cultivated. The great army of pediatricists is refusing to go half way. I think it is ethical for us to urge them to do it and to urge the people to pay them.

DR. J. L. MORSE: That is a large part of my work, Dr. Kelley.

DR. E. R. KELLEY: But you are an exception. That is, people are ready to pay for the advice. There are one or two men in Boston and one or two in the Middle West and Dr. Mason in Baltimore who are all actively hammering on that point throughout the country, but most pediatricists are not trying to practise preventive pediatrics.

The point brought up as to the exceptional opportunity of the woman physician is to a limited extent true. So much has been said about women not being wanted to be considered as women *per se* nowadays, that I have grown chary about bringing it up; but I agree that there is a peculiar opening in the child hygiene service for woman physicians. They can get the approach to the mothers quicker than the average male pediatricist. I don't think that holds, however, after the individual acquaintance has once been made.

Then we have to look at this question along statesmanlike lines. After all we are faced with the grave uncertainties of race as a world-wide problem, and one fundamental fact which we can get from the chaos of facts is that the birth rate of the white race is going down and the only thing we can do is to save more of those who are born. So from the patriotic basis the child hygiene movement ought to be advanced. We are not going to have unrestricted immigration in the future, and the future of this movement depends on the patriotism and self-sacrifice with which the people of this country take up this question.

The points which Dr. Morse raised I don't know how to answer. It is, I feel, unfair to the nursing profession and to the social workers. We have to stand that trying attitude of the nurse and social worker. On the other hand, there is another side to it which you will never adequately comprehend so long as you stay in clinical medicine. You have got to get out of it and you have got to get to the point where the nurses and non-medical public health workers will have confidence in you. Then you learn they have a feeling that they are being pushed aside by the lieutenant of the physician. After a while when they find perhaps they haven't made so many more mistakes than he they rise to a point of indifference to the doctor's attitude. I think Dr. Morse's way of

solving the problem isn't right. The social workers are guilty of many errors of omission and commission, but there is also another angle to it, and that is the need of the medical profession reaching them when they are young and plastic and to teach them in a sympathetic and broad-minded fashion how best to do their work and pay proper ethical tribute to the medical man's rights. I think they can come back at us and say they haven't had that treatment from the medical profession. I once had this point of view fully presented to me by a nurse who spoke of the growing breach between the medical and nursing professions. She was both a daughter and a granddaughter of a physician and knew the medical side of it.

TONSILLECTOMY IN THE CONTAGIOUS DISEASES.

By EDWIN H. PLACE, M.D., BOSTON.

THE importance of the tonsils in the acute infections as a point of attack and as a portal of entry for infections, as, cervical adenitis, cervical cellulitis, arthritis, endocarditis, pericarditis, septicaemia and pyaemia, etc., is so much a matter of common experience as to require no demonstration here. In scarlet fever and diphtheria this is particularly striking. In scarlet fever occurring in tonsillectomized cases the throat symptoms are almost invariably slight even to the point of absence. In a few cases under my observation in which only one tonsil had been previously removed the tonsillectomized side of the throat was nearly normal, while the tonsillar side showed the usual throat picture of scarlet fever. Severe faucial diphtheria is excessively rare in tonsillectomized cases, and when diphtheria of the throat occurs in such cases it is posterior to the posterior pillars. It is not in the scope of this paper to enter a discussion of the function of the tonsils if any. In our experience there has been little, if any indication of a deficiency in the resistance of tonsillectomized cases. In spite of abundant evidence of the disastrous part played by the tonsils in the acute contagious diseases a tremendous conservatism has looked askance at any operative procedures in these cases. This has been chiefly on the basis that the throat wound would increase the danger of infection and partly because of the fear of anesthesia complications, hemorrhage, etc. In the early days of our experience, beginning in 1906, a few operations were unfavorable, no benefit occurring. This was, however, when tonsillotomy rather than tonsillectomy was practised. The harmlessness of the operation was early brought to my attention by a case of a school teacher who was operated on the second day of a severe tonsillar infection. She had had many previous sore throats and the operation was planned for the next vacation. Before this time, however, she developed a severe throat and decided to have her tonsillar illness and operation at the same time for economic reasons. The afternoon of the same day, it was found that the throat infection was that of scarlet fever. Although the onset was severe the decline was extremely rapid

and satisfactory and no complications occurred. The throat was not more than usually sore for tonsillectomy and less sore than most cases of scarlet fever of the severity of her attack. Since then a more and more favorable attitude toward tonsillectomy and adenoidectomy has developed and this paper is an analysis of all cases operated on at the South Department in the past five years. One must appreciate that these patients are very prone to complications throughout the course of their disease, and even if the operation is favorable in general that some complication may occur following it. It is, moreover, difficult to determine whether the tendency to complication is greater or less after operation, as the operative cases are particularly selected because of factors which favor complications in this group as against the control groups.

SCARLET FEVER.

122 cases of scarlet fever were operated. The ages were as follows:

Years	Cases	Years	Cases
$\frac{1}{2}$ -1	2	8	9
2	9	9	6
3	18	10	4
4	16	11-15	13
5	16	16-20	2
6	13	21-25	4
7	10		

The time in scarlet fever at which operation was performed was as follows:

Time of Disease	Cases	No. developing complication after operation (excluding contagious diseases)
2nd day	2	0
3rd "	7	2
4th "	3	0
5th "	1	0
6th "	3	0
7th "	1	0
2nd week	5	0
3rd "	4	1
4th "	15	3
5th "	12	3
6th "	11	4
7th "	9	2
8th "	9	1
9th "	4	3
10th "	5	0
11th "	4	2
12th "	5	2
13th "	3	1
14th "	5	2
15th "	3	1
16th "	3	1
17-24th "	8	0

The complications of scarlet fever in this group preceding operation were:

Cases	Cases
Otitis media	16 Arthritis
Rhinitis	40 Mastoiditis
Septic sore throat	21 Bronchopneumonia
Cervical adenitis	15 Measles
Periodic fever	7 Diphtheria
not accounted for un-	Peritonitis
less by tonsils	Pertussis

Cases	Cases
Endocarditis	2 Pyelitis
Bronchitis	2 Impetigo
Tonsillitis, secondary	2 Corneal ulcer
Sc. fever reinfection	2 Pleural effusion
Nephritis	2 Pericarditis
Parotitis	2 Persistent tonsillitis
Catarrhal jaundice	2 T. B. of adenoid
Burn	1

No complications were present in 23 or 18.8% but of these 11 were operated on in the early or acute stage. There was a previous history of frequent sore throats in 26 cases, adenitis in 3 and otitis media in 3.

The complications following operation were as follows:

Cases	Cases
Transient fever	13 Broncho-pneumonia
Rise in pulse rate	9 (after measles)
Otitis media	7 Broncho-pneumonia
Haemorrhage	5 Infection of jaw
Measles	3 Retropharyngeal ab-
Cervical adenitis	2 secess
Mumps	2 Septic sore throat
	Antrum abscess

There were no complications after operation in 90 or 73.7%.

Analysis of the complications occurring after operation shows the following:

Temperature rise after operation:	Av. Highest temp.
Duration Cases Highest points	
1 day 4 100.5-103	101.1
2 " 4 100-102.5	101
3 " 4 100.5-103	101.3
7 " 1 102	

In the case having fever for 7 days there had been a similar fever for one week preceding operation.

These cases were operated from the 6th to the 15th week of scarlet fever. The acute cases are not included.

Pulse rise.	Cases	Highest Rate
Duration		
1 day	1	168
2 "	2	125
3 "	3	130
4 "	2	130
2 wks.	1	130

Post-operative haemorrhage. Post-operative haemorrhage was moderate in two cases and slight in three, occurring 14, 16 and 23 hours after operation. It was not alarming and was readily controlled. These cases were operated in the 4th, 6th, 7th and 12th weeks of scarlet fever.

Operative haemorrhage was not abnormal.

Otitis Media. Otitis media occurred for the first time after operation in four cases as follows:—

4th day in one case lasting 5 weeks,
5th day in one case lasting 2 days —
red drum without discharge,
13th day in one case lasting 9 days,
24th day in one case lasting 10 days.

Otitis media occurred following operation in cases which had had otitis media during the acute stage of scarlet fever as follows:

- 12th day, persisting one week.
- 10th day, persisting for one week in a case which had had otitis media at onset, persisting 6 weeks
- 8th week after operation, persisting 2 weeks.

The patients developing otitis media for the first time after operation were operated on the 4th, 7th and 5th week and the third day respectively.

Broncho-pneumonia. One patient developed broncho-pneumonia 40 days after operation on the 5th day of measles. The lung was clear in 10 days.

One patient, age 1, who had been returned to hospital because of a contagious nasal discharge developed broncho-pneumonia 19 days after a favorable post-operative convalescence and died on the 31st day. These cases were operated on the 3rd day and 9th week of scarlet fever respectively.

Local Sepsis. One patient developed a septic process in throat and nose beginning 14 days after operation with swelling and redness of throat and nasal discharge for a period of one week. He was operated on the third day, when he had a severe septic throat with extensive membrane and tonsils nearly meeting in median line. He later developed measles and broncho-pneumonia.

One case operated in the 5th week developed adenitis on the 5th day with a small abscess opened on the 12th day with rapid recovery.

One case operated on in the 5th week had small glands in neck one week after operation for a few days.

A swelling of jaw developed in another case the day after operation, clearing in 2 weeks.

In one case which had been running an irregular temperature for one week before operation with slight glandular swelling, nasal discharge and swollen tonsils, a retropharyngeal abscess developed and was opened on the 6th day after tonsillectomy.

One case developed nasal discharge at end of one week and later was operated for antrum. There was a history of frequent nasal discharge previous to scarlet fever.

Reinfection. One patient developed a typical scarlet fever 3 days after tonsillectomy which had been done in the 6th week while the patient was still desquamating from the first attack. The temperature lasted 3 days, reaching 103.2, and there were no complications.

Nephritis. One patient was operated on the 3rd day of nephritis in the 1th week of scarlet fever. There was an increase of albumen on day of operation and an increase of blood cells for 5 days. The urine was normal in 1 weeks.

There was no oedema. The urine showed V. S. T. to T. of albumen with hyaline, granular, brown granular and epithelial casts, renal cells and red blood corpuscles and was smoky in color for a few days.

On examining the table on page 6 it is seen that complications occurred more frequently in cases operated late in convalescence than when operated earlier, although this may be due to differences in the cases. It does not indicate the supposedly great danger of tonsillectomy early in the disease, however. It must be recalled that the cases in this group represent chiefly cases in which complications without operation particularly threatened.

Purpose of operation and results. Many of these cases were operated because of continued contagiousness as shown by aural or nasal discharge.

Aural Discharge. Thirty-four cases operated, all but 5 cleared within 6 weeks.

Ear discharge stopped in 4 days.	4 cases
Ear discharge stopped in 8 days.	11 cases
Ear discharge stopped in 10 days.	5 cases
Ear discharge stopped in 14 days.	3 cases
Ear discharge stopped in 4 wks.	5 cases
Ear discharge stopped in 6 wks.	1 case
No benefit	5 cases

Nasal Discharge. Thirty-nine cases were operated because of nasal discharge.

Nasal discharge ceased in 1 wk.	6 cases
Nasal discharge ceased in 2 wks.	18 cases
Nasal discharge ceased in 3 wks.	5 cases
Nasal discharge ceased in 4 wks.	2 cases
Nasal discharge ceased in 8 wks.	1 case
No benefit	7 cases

Three patients were operated because of cervical adenitis, with rapid subsidence of glands in all.

Others were operated because of peritonsillar abscess, frequent sore throats, obstruction, dyspnoea, difficult deglutition, poor general condition, persisting infection in tonsils or adenoids, etc.

In the acute stage of the disease tonsillectomy was performed in 18 cases. In two cases complications occurred in convalescence.

In one case, No. 63068, age 4 years, there was a history of sore throat frequently and very many colds. There has been an abscess of the neck and the patient was a mouth breather. The tonsils were very large, nearly occluding fauces, and there was nasal obstruction. Operation on the 3rd day of scarlet fever. On the 9th day there was a nasal discharge, which continued for a long period. The antrum was opened several months later. In the other case, No. 62508, 3 years old, the patient was operated in the (third day of scarlet fever, at which time there was a moderate septic throat with patches of membrane on each tonsil. Fourteen days after operation, fever, swelling of the throat, and

within a week, nasal discharge. Three weeks active otitis media. Within 10 days lungs and after operation aural infection occurred. By the ears had cleared. As tonsillectomy in the acute stage of scarlet cleared. On the 35th day measles developed, fever is unusual, the detail of these cases is followed by pneumonia on the 5th day, and an given in the accompanying table.

Reference number	Age	Day of disease operated	Condition	Course
60970	14	2nd	Frequent sore throats. Large red tonsils with marked crypts, some exudate on post pharynx and slight oedema of uvula. Mod. mild case. T. 100.	Temp. normal in two days. Throat healed in 10 days. No complications.
60792	5	6th	Marked swelling of tonsils, left to median line, right to $\frac{1}{2}$ cm. from median line.	Temp. normal in one day. No complications.
60862	9	3rd	Tonsils much enlarged, marked crypts with exudate. Mod. mild case. T. 100.5.	Temp. normal in 3 days. Throat healed in 3 wks. No complications.
65101	10	3rd	Right tonsil buried. Left tonsil mod. enlarged, exudate on surface. Mod. case. T. 101.5.	Temp. normal in 2 days. Throat healed in 3 wks. No complications.
65086	10	4th	Tonsils much enlarged. Thin membrane on surfaces. Glands at angle of jaw much enlarged. Tonsils exuded pus on pressure. T. 103.	Temp. normal in 24 hrs. Throat healed in 3 wks. No complications.
65130	2	3rd	Tonsils enlarged. Pus exuded on pressure. Very large adenoid mass.	Temp. normal in 3 days. Throat healed in 4 wks. No complications.
65387	6	4th	Tonsils markedly enlarged, exudate on each and on uvula. Mod. case with septic throat. T.	Temp. normal in one day. Throat healed in 11 days. No complications.
65817	4½	6th	Catches cold easily, mouth breather and is said to be mentally backward. Tonsils meet in median line. T. 100.5.	Temp. normal in 3 days. Throat healed in 2 wks. No complications.
66446	14	6th	Several attacks of tonsillitis. Tonsils mod. enlarged. Exudate in crypts. Moderate case. T. 102.	Temp. normal in one day. Throat healed in 2 wks. No complications.
66904	5	3rd	Tonsils large, ragged, marked crypts. T. 102.	Temp. normal in one day. Throat healed in 3 wks. No complications.
61748	19	5th	Tonsils moderately enlarged. Mild case. Temp. normal.	Temp. normal. Throat healed in 4 wks. No complications.
65104	6	2nd	Had had otitis media, and present illness began with earache and red drums. Tonsils mod. enlarged, covered with exudate.	Temp. normal in 2 days. Throat healed in 3½ wks. No complications.
63417	4	8th	Always had large tonsils, and has occasional sore throats. Tonsils large, meet in median line, some exudate. Breathing through mouth, which is noisy and somewhat difficult.	Throat healed in 2 wks. No complications.
65120	5	3rd	Recurrent tonsillitis. Tonsils large and almost meet in median line. Yellow exudate over surface.	Temp. normal in 2 days. Throat healed in one wk. No complications.
65626	7	7th	Frequent tonsillitis. Tonsils large with marked crypts. T. 103.	Temp. normal in 2 days. Throat healed in 2 wks. No complications.
66142	6	4th	Tonsils markedly enlarged. Almost meet in median line. Thin film of membrane over surfaces.	Temp. normal in 2 days. Throat healed in 12 days. No complications.
63068	4	3rd	Many colds and sore throats. Abscess of the neck. Mouth breather. Tonsils very large, nearly occlude throat, and covered with film of exudate. T. 100.8. Glands at angle of jaw.	Temp. normal in 3 days. Nasal discharge on 9th day continued thru convalescence. Rt. antrum opened 15th wk. No fever during convalescence.
62808	3	3rd	Tonsillitis 2½ years before. Tonsils much enlarged, almost meeting. Patchy membrane on left, slight on right. T. 102.8.	Temp. normal in 3 days. 14 days after operation throat red fever. During next week swelling of

throat, nasal discharge, etc., with high fever. Third week aural discharge. Fourth week throat clear, aural and nasal discharge cease. 35 days after operation measles. 40 days after operation pneumonia, and again discharge from ears. 45 days after, lung clear and ears clear.

DIPHTHERIA.

In diphtheria, diphtheria carriers, septic sore throat, tonsillitis, chorea, etc., tonsilleectomy has been performed 74 times during the past five years.

In the diphtheria carriers 39 cases were operated upon because of the carrier condition. Of these, 36, or 92.3%, were cured within four weeks; 32, or 82%, were well in two weeks.

Diph. free	Cases	Percent.
Within 1 week	16	41
Within 2 weeks	16	41
Within 3 weeks	2	5.1
Within 4 weeks	2	5.1

Three patients were not benefited by operation. All proved to be non-virulent and were discharged.

The details of these cases is given in the accompanying table.

These cases were selected from the diphtheria carriers as being favorable for operation by culturing various regions as each tonsil, pharyngeal wall, and nostrils. The tonsillar carriers were operated on. Occasionally other than tonsillar carriers were included.

DIPHTHERIA CARRIERS.

Case	Reference Number	Age	Week of Disease Operated	Cultures Before Operation	Cultures After Operation
1	61323	29	8th	21 consec. cultures, 10 positive.	Immediately after operation 7 consec. negative cultures.
2	61405	8	4th	7 consec. pos. cult.	One wk. after operation, 7 consec. neg. cultures.
3	60938	5	?	Several positive.	All cult. neg. for a month.
4	60853	4½	4th	11 consec pos. cult.	Next 23 cult., 5 neg. One month later 6 consec. neg. cultures.
5	61559	9	7th	35 cult. 31 positive.	After operation, 10 cult., 8 neg. All neg. after 10 days.
6	54155	25	2nd	13 cult. 8 positive.	No effect. Non-virulent. 52 cult., 36 neg.
7	61664	21	7th	24 cult. 11 positive.	One wk. after operation, 12 cult., 11 neg.
8	64556	8	11th	18 cult. 16 positive.	11 cult., 7 neg.; 12 days after operation, 7 consec. neg. cult.
9	65128	7	6th	19 cult. 10 positive.	6 days after operation, 6 consec. neg. cult.
10	65187	5	4th	11 cult. 10 positive.	One week after, 6 cult., 5 neg.
11	65328	7	5th	15 cult. 5 positive.	One wk. after, 7 consec. neg.
12	65316	11	7th	25 cult. 17 positive.	One wk. after, 14 cult., 13 neg. All neg. after 11 days.
13	65522	4	4th	13 cult. 9 positive.	15 cult. 13 neg.
14	65501	3½	7th	14 cult. 10 positive.	Nine days after, 6 consec. neg. cultures.
15	65610	19	3rd	0 cult. 8 positive.	Nine days after, 6 consec. neg. cultures.
16	65828	21	3rd	12 cult. 11 positive.	Ten days after, 7 consec. neg.
17	65889	5	1th	15 cult. 13 positive.	Eight days after, 12 cult., 11 neg.
18	65920	5	8th	23 cult. 18 positive.	34 cult., 20 pos. No benefit, nonvirulent.
19	66108	2½	5th	17 cult. 16 positive.	Five days after, 5 consec. neg.

Case	Reference Number	Age	Week of Disease Operated	Cultures Before Operation	Cultures After Operation
20	6101	6	10th	35 cult. 18 positive.	Ten days after, 9 cult., 8 neg.
21	66178	3	5th	16 cult. 15 positive.	Six days after, 7 consec. neg.
22	66151	10½	3rd	18 cult. 14 positive.	After op., 20 cult., 11 neg.; 27 days after, 7 consec. neg.
23	61213	17	9th	50 cult. 34 positive.	2 days after, 7 cult., 6 neg.
24	61160	4	3rd	13 cult. 7 positive.	3 days after, 17 cult., 9 neg.; all neg. in 3 weeks.

35	63620	22	3rd	5 cult. All positive.	One week after, 10 cult., 8 neg. All neg. after 8 days.
36	60238	7	7th	Cult. positive for one month.	One week after op., neg. cult. for 13 consec. days.
37	59945	?	3rd	7 cult. 2 positive.	Three days after, neg. for 9 consec. days.
38	58602	21	4th	8 cult. 7 positive.	One week after, cult. neg. for 6 consec. days.
39	61440	12	4th	19 cult. 14 positive.	Three days after op., 6 consec. neg. cult.

The complications in this group were as follows:—

Fever transient	8 cases
Rise in pulse	4 "
Mumps	1 case
Erysipelas of face	1 "
Diphtheria of wound (?)	1 "
Hemorrhage	1 "
Bronchopneumonia	1 "
Cervical adenitis	1 "

The bronchopneumonia occurred in a two year old child operated in the eighth week after a normal convalescence; pneumonia developed on the tenth day and was fatal in one day. During the third week of convalescence, one patient had had a cervical adenitis and abscess.

One case had tuberculosis of tonsils and adenoids.

The operative procedures were nearly uniform

in these cases. Light ether anaesthesia with the open method was used. The sitting posture was used nearly exclusively. The dissection of the tonsils was done with Monahan's blunt dissector and snare, chiefly, a method which produces but little trauma and gives excellent results.

I feel that the technique is especially important in these cases, that the ether should be light, the trauma as little as possible, and the operation as short as possible.

CONCLUSIONS.

1. Tonsillectomy and adenoidectomy are valuable means of shortening the contagiousness of scarlet fever and diphtheria in suitable cases.

2. There is reason to believe that early operation in scarlet fever tends to reduce the danger of complications.

3. Operative dangers are not great; haemorrhage is not more marked than in other conditions.

4. Local infection, although not excluded by operation, is less common than usually occurs in non-operative cases.

5. Bronchopneumonia occurred three times in 196 cases, once being after measles, but in no case did symptoms appear earlier than ten days after operation.

DISCUSSION.

Dr. C. R. C. BORDEN, Brookline: According to his usual wont, Dr. Place has been very modest concerning the outcome of his investigations. Did time but permit, it would give me pleasure to tell you of a great many brilliant results which have been obtained in the South Department during his administration.

As regards the subject under discussion, he has left very little for me to add, since my experience in the removal of tonsils during scarlet fever has in recent years been comparatively slight. Doubtless I performed some of the operations which he mentioned as not being particularly successful, but that was some time ago, before the operation had reached its present state of development.

When I became connected with the Aural Department of the Boston City Hospital, chronic discharge from the middle ear was the bane of our existence. We had dozens of such cases every day, whereas at the present time there are relatively few.

The wholesale removal of adenoids and tonsils in hospitals and in private practice is the most prominent factor in the diminishing number of cases of otitis media.

I was delighted to hear Dr. Place say that a number of tonsils operated during scarlet fever cured acute otitis media. If every case of aural discharge persisting more than two or three weeks should have the tonsils and adenoids removed, deafness and mastoiditis in the future would be relatively rare. Even at the present time the patients coming to specialists' offices for relief from deafness are gradually becoming fewer and fewer, and in the large cities there will probably be comparatively little of it in the future.

Another point brought out by Doctor Place I wish particularly to emphasize, namely, the recognition and diagnosis of profuse nasal discharge. Such a discharge as that often seen in scarlet fever is frequently the beginning of nasal sinus disease, which is so troublesome later in life. As nasal sinus disease is much more common than the profession at large

realizes, it is our duty to bring about a better understanding of the significance of its far-reaching influence. It is a powerful factor, in many cases of asthma, cough, arthritis, indigestion, and probably heart and kidney infections of various degrees and intensity.

Inflamed tonsils and adenoids are often the primary source of infection of the nasal sinuses. Consequently the removal of infected lymphoid tissue will bring about marked improvement throughout the mucous surfaces of the nose.

Once or twice a year, I am called upon to see some desperately sick child in which no cause can be found for prostration and high temperature. I should like to mention one case seen in consultation with Dr. Place and Dr. Hastings in the Brookline Contagious Hospital, since it illustrates very well three particular points which I wish to emphasize. A young girl seven years old was admitted to the hospital a few months ago with a very light case of scarlet fever. Several weeks later she became very ill and developed a high temperature, but physical examination by Dr. Place and Dr. Hastings failed to discover any particular reason for her condition. I was then invited to see the case, and found nothing except a shiny, pink eardrum. There was little or no bulging of the drum; there was a partial light reflex present; there was no swelling of the canal wall and no tenderness or swelling over the mastoid. Incision of the drum was not followed by discharge or by any cessation of the symptoms. The child continued to be very ill; finally, because nothing definite elsewhere could be determined, Dr. Place and Dr. Hastings allowed me to open the mastoid, which, in the absence of any other symptoms, I was convinced was the real cause of her troubles. When the mastoid cortex was exposed, the first blow from the hammer and the chisel uncovered a cavity in the mastoid which occupied its whole interior. When the rest of the bone was taken from the cortex, the mastoid cavity was found to be very red and dry. There was practically no bleeding, and it required very little operating to enter the mastoid antrum and find this direct communication to the middle ear. Some bleeding occurred at this point, but very little. There were one or two very suspicious cells behind the jugular vein, which was freely exposed. The mastoid had all the appearance of being tubercular, but unfortunately no cultures were taken and no pieces of bone were saved for examination.

Shortly after the operation the temperature fell to normal and never went up again except once temporarily, which was probably due to some disturbance in the digestive tract. The child recovered slowly, because of her extreme prostration, but finally left the hospital in good condition. As previously stated, this case emphasizes three points. First, the parents took the child to their family doctor some months before and asked if it were necessary to have the tonsils and adenoids removed. The doctor advised against it, and told them to wait until she was older. Doubtless, had her tonsils and adenoids been removed at that time, her serious illness would not have occurred. Secondly, there were few symptoms pointing to mastoiditis; but had we waited for the cardinal symptoms as given by text-books and lectures on the subject, I am sure this child would have died. Thirdly, I am positive that this particular case would have become one of chronic mastoiditis were it not for the effective results obtained from a two and one-half per cent. solution of mercurochrome. In all my experience with mastoiditis, coincident with scarlet fever, I have never seen a case better suited to become chronic than this was, because of the peculiar tubercular-like appearance of the bone. After the first dressing was taken down, this wound was filled with the mercurochrome solution, which was allowed to remain in place for half an hour, five times a day,

Later, the number of applications was decreased. The wound healed rapidly and cleanly; today it is healed, and the hearing is normal. Not only did the wound heal, but the stitches used to draw the skin together at the top and bottom of the wound held in place, without infection or without cutting through, for more than seven days. This is the only case in my experience where I have been able to make sutures hold in scarlet fever. In every other case they have cut through, or become infected within three days.

When the adenoids were removed in this case the greater part of the lymphoid mass was removed with a Gottstein curette; but when the finger was inserted behind the palate, the sides of the pharynx and the spaces round the eustachian tube were so filled with remaining adenoid tissue that the finger experienced the same sensation as if it had been inserted into a tub of soft butter. The tissue, of course, was curetted away by the finger nail.

Primary mastoiditis practically never occurs. In a large series of autopsies in the Contagious Department of the Boston City Hospital, if I remember rightly, but one instance occurred in which the question of primary mastoiditis was raised. In every other case it was secondary to the ear, nose, or throat.

Such being the case, it becomes our duty in every case of a scarlet-fever middle-ear complication to anticipate the more serious developments of mastoiditis, and to remove infections in the nose or throat before the middle-ear condition has become sufficient to be a serious menace to the patient's life or to the future of his hearing.

Dr. Place, of the Boston City Hospital, Dr. Hastings, of the Brookline Contagious Hospital, and Dr. Morse of the Somerville Contagious Hospital, realize this to its full extent, and are constantly watching their patients lest they develop chronic middle-ears, mastoiditis, fungular thrombosis, meningitis, and so forth.

Dr. Place's paper today will, I am sure, spread broadcast this most important subject, and I feel confident it will do much to banish the fear held by so many physicians and specialists—viz., that scarlet fever, in the present or in the past, does not contraindicate the removal of infected tonsils and adenoids.

Dr. E. H. Place, Boston (closing): I might speak about the case that Dr. Borden spoke of. I quite agree that the operation did a great deal of good. I don't know what would have happened if he had not done it. I saw the girl after he did and found nothing to account for the temperature except the ear. He opened the ear without getting pus, and she showed no mastoid symptoms at all. The only local infection in that case was a mastoid which was apparently primary. The only cases of mastoiditis I have seen which were primary were tuberculous. One of my cases had five operations on the mastoid and recovered, but I think she has pulmonary tuberculosis now.

SPECIAL NOTICE

The Boston Medical Library, permanent headquarters of The Massachusetts Medical Society, 8 The Fenway, Boston, desires contributions of books, periodicals, pamphlets, medical photographs and autographs, and whatever relates to medicine. Do not throw away or sell for junk anything of a medical or scientific nature, no matter how worthless it may seem, without first giving the Library the privilege of examination.

Original Article.

AN INVESTIGATION OF THE RELIABILITY OF LABORATORY TESTS AND A DISCUSSION OF TECHNIQUE OF LABORATORIES IN AND NEAR BOSTON.

By FRANCIS H. SLACK, M.D., BROOKLINE, MASS.

*Director, Sias Laboratories, Brookline, Mass.,
Instructor in Public Health Laboratory Methods,
Massachusetts Institute of Technology.*

FOREWORD BY DR. WM. C. WOODWARD, FORMERLY
HEALTH COMMISSIONER, BOSTON, MASS.

IN May, 1919, the writer was impressed with the importance of determining the accuracy of diagnostic and other work done in the bacteriological laboratories in and about Boston. He had no reason to believe that conditions here were different from conditions in other places, but Metropolitan Boston is made up of so many independent cities and towns and contains so many clinical laboratories, public and private, in which bacteriological work is done, that the situation obtruded itself more forcibly, probably, than it would have done in other places. Action was taken toward the desired end by arranging for cooperation between the responsible directors of two bacteriological laboratories of unquestionable standing, with the hope that if cooperation between these two could be effected, then cooperation on the broader scale would follow. The plan was unsuccessful, however, the work consuming too large a part of the time of the directors of the laboratories participating in it.

Foiled in efforts along the line named, the writer appealed for aid to Professor William T. Sedgwick, then professor of biology and public health at the Massachusetts Institute of Technology. Professor Sedgwick cheerfully consented to direct the inquiry and to furnish the necessary technical assistance, but could not provide the money. An appeal was made to the Committee of the Permanent Charity Fund, Inc., who, upon being convinced of the importance of the objects to be obtained and of the fact that money was not available from other sources, made the necessary grant. The reasons submitted to the Committee of the Permanent Charity Fund in the appeal that was made for assistance seemed to represent a complete justification for the expenditure and were as follows:

"In the interest of the public the Health Department of the City of Boston, through its bacteriological laboratory, is continuously making examinations to determine whether persons from whom specimens are submitted by their attending physicians are or are not suffering from a communicable disease, to determine the nature and extent of the bacteriological contamination of milk, etc.,

"It is manifestly of vital importance to the community and to the patient that the results of such examinations as are made to determine the presence or absence of communicable diseases be as nearly accurate as human care, knowledge, and skill can make them. To report that a smear from a case that a physician suspects of being a case of gonorrhoea shows that the case is that disease may create suspicions that no subsequent discovery of error and no amount of subsequent explaining can remove, and may wreck the happiness of a family. To report that a similar specimen shows no evidence of gonorrhoea when the question of marriage hangs on the decision may, if an error be made, ruin the health of the young wife and bring blindness to the offspring. Similarly the welfare of the individual and the safety of the community are inextricably bound up in the reports of the laboratory as to whether given cases are or are not syphilis, or tuberculosis, or diphtheria, or typhoid fever, or cerebro-spinal fever, or malarial fever, and so on.

"In the case of examinations made in connection with the efforts of the department to insure the wholesomeness of the milk supply, the safety of swimming pools, and so on, errors may lead to a false sense of security on the one hand, with consequent disaster, and on the other hand may lead to unnecessary expenditure of money, energy and time in efforts to right evils that do not exist."

The history and results of the investigation are fully set forth in the following report. Technical recommendations for the standardization and control of laboratory service, which are chiefly of interest to those engaged in laboratory work, are presented in a separate article for those interested in the purely laboratory aspects of the situation. To the administrative health officer and, above all, to the people, the matter of primary concern is not so much the standardization of procedure as the establishment of some method of supervision and control whereby laboratory errors and misinterpretation of laboratory reports will be reduced to a minimum.

It would seem clear that if physicians, pharmacists, dentists, veterinarians, and even chiropractors are required to satisfy the state of their fitness to follow their chosen callings before they are permitted to do so, then that persons who venture to presume that they are capable of doing clinical laboratory work should be tested in like manner before they begin to hold themselves out to the public, either in governmental or private laboratories, as qualified to do so; and some assurance should be required in every case that the laboratory equipment possessed by the would be laboratory worker is adequate for the purposes for which he uses it. Possibly some such method of control, by requiring a license as a condition precedent to engaging in laboratory work as a means of livelihood, might be tolerated, for the present at least, inasmuch as that is the method of control applicable to the

other callings named above. It would seem better even in such cases, however, and it would certainly seem necessary with respect to all governmental laboratories, that there be some adequate system of measuring the accuracy of their work from time to time and requiring that work to be up to standard. A peddler must produce scales of the required fineness before he can begin crying his wares, but, furthermore, he must have those scales tested from time to time to see that they retain their accuracy. So the public is entitled to demand that workers—at least in government laboratories—not only are qualified when they enter upon laboratory service but that they remain qualified during their entire period of service and that they do not fail through carelessness or rush of work to exercise their qualifications for the safeguarding of patrons of their laboratories.

To the end last named, there should certainly be established some system of measuring—of auditing, if you will—the accuracy of the reports issued from government laboratories. Such a system of checking up the work of these laboratories would not be difficult, provided only that money be provided for the employment of competent men for such work, with authority to use such measures as they saw fit for determining the accuracy of the results of any laboratory. Such work may well be entrusted to state medical licensing boards, or to state health authorities, but in the latter case, provision would have to be made for determining by some independent agency the accuracy of the work of the laboratories maintained by the state health authorities, which are certainly no more immune from error than are the laboratories in the municipal health departments. Possibly, after all, the establishment of an independent board for such supervisory work might best solve the problem.

Certainly, no fair-minded laboratory worker could object to such a system of supervision as is suggested above. It is just such a system of supervision as the most responsible financial interests of the country are by law subjected to, and such supervision as the financial departments of all large corporations expect from their stockholders and directors. If the work of the laboratory is above criticism, then an inquiry into it, such as is now proposed, will do the laboratory no harm and will tend to reassure the public and, particularly, the medical profession with respect to its work. If the work of the laboratory can be improved, then such supervision should show the way. Clearly it would be the part of wisdom on the part of state and municipal governments to provide such money as may be necessary, and to grant such authority as may be necessary, for the effective supervision and control of the laboratories established and maintained by them for the benefit of their citizens.

I cannot close without recording my appreciation of the valuable service rendered by Pro-

fessor W. T. Sedgwick, Professor S. C. Prescott, Dr. L. S. Medalia, and Dr. F. H. Slack, and of the spirit of willing coöperation manifested by the several laboratories that were asked to coöperate in the investigation. I am under deep obligation, too, to the Committee of the Permanent Charity Fund, Incorporated, for the financial assistance rendered by it, without which the investigation would have been impossible. The investigation has, I feel, been well worth while, and it should point a way toward better laboratory organization and administration not only in Boston but wherever public health laboratories for the service of the community are maintained.

A COMPARISON OF REPORTS FROM SEVERAL DIAGNOSTIC LABORATORIES ON FOUR COMMON TESTS: DIPHTHERIA, TUBERCULOSIS, TYPHOID FEVER, GONORRHOEA.

PART I.

This report is a result of the initiative of Dr. Wm. C. Woodward, formerly Commissioner of Health for the City of Boston, through whom the Committee of the Permanent Charity Fund, Incorporated, became responsible for a study of the technique of various laboratories in or near Boston, a comparison of the work done, through the submitting of identical samples and an effort to establish uniform procedure.

The late Prof. W. T. Sedgwick of the Massachusetts Institute of Technology was asked by Dr. Woodward to oversee this study and to assign workers from the Biology Department to prosecute it under his supervision. Under his direction Professor S. C. Prescott sent a circular letter to the various laboratories in March, 1920, and received a cordial response to his request for coöperation.

About June 1, 1920, Dr. L. S. Medalia took charge of the investigation and for several months devoted much of his time to a visitation of the laboratories and a study of the methods and technique of each.

On his request typewritten copies of the technique in use were submitted from the Boston Health Department laboratory, the State Health Department diagnostic laboratory, the State Wassermann laboratory and from the Board of Health laboratories in Brookline, Cambridge and Somerville.

Dr. Medalia drew up charts comparing the technique in use in these and other laboratories for the diagnosis of diphtheria, tuberculosis and typhoid fever. He also called several meetings of laboratory directors for a discussion of the technique used in these tests.

In May, 1921, owing to the pressure of other work, Dr. Medalia felt obliged to drop this investigation, and the writer was asked to continue it.

Following the programme outlined for the work, this was done by submitting various series

of specimens to the laboratories for diagnosis, a comparison of the reports and repeated conferences of the workers for discussion of technique. As an outcome of the discussion a code of minimum standards has been accepted.

The writer acknowledges with appreciation the hearty coöperation of the following laboratories in carrying out these tests, including, besides those mentioned in this paper, Wassermann tests and examination of milk: Boston Biochemical Laboratories, Boston City Hospital Pathological Laboratory, Boston Dispensary Laboratories, Boston Health Department Bacteriological Laboratory, Boston Health Department Bureau of Milk Inspection, Brookline Health Department Laboratories, Brookline Health Department Laboratory, Cambridge Health Department Laboratory, Homeopathic Hospital Pathological Laboratory, Massachusetts General Hospital Pathological Laboratory, Massachusetts State Department of Health Bacteriological Laboratory, Massachusetts State Department of Health Wassermann Laboratory, Newton Health Department Laboratory, Newton Hospital Laboratory, Peter Bent Brigham Hospital Pathological Laboratory, Wellesley Health Department Laboratory.

DIPHTHERIA.

Through the courtesy of Dr. E. H. Place of the Boston City Hospital, South Department, the first series of diphtheria cultures was taken from patients and attendants there. Ten cultures were taken. The swabs in each case were then rubbed thoroughly over the surface of as many tubes of blood serum media as there were laboratories taking part, and to make sure of a thorough inoculation the process was repeated. The last serum in each case, which presumably received the least material, went to Laboratory No. 7. All the serums were delivered to the various laboratories on the same day.

The results of this first series of tests were rather disappointing, evidently where the bacilli were few, as in Nos. 1 and 3, they were either overgrown or overlooked in over 50 per cent. of the cultures.

Brief histories of these ten cases follow:

CASE NO. 1. No. 64724. Age five years. Admitted April 15, 1921. *Diagnosis:* Clinical nasal diphtheria. *P. E.:* Bilateral muco-purulent discharge from nose with crusting. No membrane seen. Positive culture from nose and throat at entrance. *Course:* Received antitoxin at entrance. Uneventful course till May 21, when adenoids were removed. Throughout convalescence positive cultures were obtained until June 10, when gentian treatment was used for one week and then omitted for one week, subsequent to which all cultures from nose and throat were negative. Virulence test not done. *Diagnosis:* Nasal diphtheria.

DIPHTHERIA TESTS—TABLE I.

*c=contaminated.

CASE No. 2. No. 64755. Age six years. Admitted May 11, 1921. *Diagnosis:* Typical mild faucial diphtheria. Positive cultures from the nose and throat. Received antitoxin at entrance. *Course:* Uneventful convalescence. Was discharged well at the end of three weeks. Discharge cultures all negative. *Diagnosis:* Faucial diphtheria.

CASE No. 3. No. 64734. Age eight years. Admitted April 18, 1921. *Diagnosis:* Typical clinical faucial diphtheria, moderate. Positive culture from throat. Received antitoxin at entrance. *Course:* Uneventful convalescence with discharge in twenty-four days. All discharge cultures negative. *Diagnosis:* Faucial diphtheria.

CASE No. 4. No. 64859. Age six years. Admitted May 7, 1921. *Diagnosis:* Faucial diphtheria. Severe toxæmia. Entrance cultures positive. Forty thousand units antitoxin given at entrance intravenously. History not obtained. Duration of illness not known. *Course:* There was considerable difficulty in breathing due to oro-pharyngeal obstruction, which was relieved by passing a nasal tube. There was a slight febrile disturbance due to antitoxin, with temperature returning to normal in twelve hours. Death followed on fifth day in hospital. *Diagnosis:* Faucial diphtheria.

CASE No. 5. No. 64873. Age twenty-one years. Admitted May 10, 1921. *Diagnosis:* Mild faucial diphtheria. Positive culture from throat. Received antitoxin at entrance. *Course:* Uneventful. Discharged in eighteen days. All release cultures negative.

CASE No. 6. No. 64688. Age seven years. Admitted April 11, 1921. *Diagnosis:* Mild nasal diphtheria? *Course:* No membrane in nose. Entrance cultures negative three successive days from nose and throat separately. Antitoxin given at entrance. Uneventful course till placed on release cultures April 26. From 26th of April to 14th of May all release cultures were negative, but patient did not go home.

From that date on, positive cultures were noted almost constantly. From May 15 to 23 gentian treatment was given. From May 28 cultures were again positive persistently from the nose and occasionally from the throat. Adenoidectomy June 3. Cultures from June 8 to 15 positive from nose and throat. Virulence test proved organism was non-virulent. *Discharge:* Patient discharged well July 16, 1921. *Diagnosis:* Nasal diphtheria.

CASE No. 7. No. 64435. Age eight years. Admitted March 4, 1921. *Diagnosis:* Mild faucial diphtheria. Positive culture from throat at entrance. Antitoxin given. *Course:* Uneventful save for otitis media. Release cultures from nose, throat and ears were negative March 17 to 21 and patient was discharged March 22. After discharge one positive culture from nose and throat returned. Patient was readmitted March 24, No. 64556, with positive culture from the nose. No antitoxin given, no Schick done. Uneventful course save for almost continuous positive cultures. Gentian treatment in April followed by positive cultures again. Regional cultures showed nose alone involved. June 3 tonsils and adenoids removed; following day had a moderately bad post-nasal hemorrhage. Cultures resumed June 10; positive till the 15th; negative through the 21st. Discharged 22d of June well. *Diagnosis:* Faucial diphtheria, tonsils and adenoids.

CASE No. 8. No. 64847. Age twelve years. Admitted May 6, 1921. *Diagnosis:* Severe faucial diphtheria. *P. E.* Patient admitted with severe faucial diphtheria with oedema of soft palate and considerable membrane. Antitoxin given at entrance. *Course:* Cultures from throat and nose, suspicious for several days, became definitely positive fourth day after entrance. Course uncomplicated save for slight evidence of kidney inflammation. Definite palatal paralysis, also knee jerks. Release cultures begun June 21 were all negative. Discharged well June 30, 1921. *Diagnosis:* Faucial diphtheria.

CASE No. 9. No. 64664. Age twenty-one years. Admitted May 9, 1921. *Diagnosis:* Streptococcus sore throat. Patient admitted with streptococcus sore throat of moderate severity. Cultures from nose and throat separately negative. Received antitoxin at entrance. *Course:* Moderate serum reaction. Out of bed April 29. Uneventful course save for occasional positive cultures among discharge cultures from April 23 to May 14, when the regional cultures showed tonsils and posterior pharynx alone involved. Then came T. and A. May 21, with resumption of cultures May 28. From May 28 to June 8 all cultures for release except the one on June 1 were negative. Patient discharged well June 9. *Diagnosis:* Streptococcus sore throat. Tonsils and adenoids removed. Bacteriological diphtheria.

CASE No. 10. No. 64855. Age four years. Admitted May 7, 1921. *Diagnosis:* Measles. *Course:* Entrance culture from nose positive. No antitoxin given. Schick negative. Uneventful convalescence. Release cultures from May 9 to 17 all negative. *Discharge:* Patient discharged well May 15, 1921. *Diagnosis:* Measles.

As indicated in the histories, many of these were release cultures, and on this account more difficult for examination. Most of the errors consisted in passing as negative cultures containing but few bacilli. Laboratory No. 5 reports a positive result on culture 10, which all others report negative. Laboratory No. 9 seems over-cautious.

In preparing the material for the second series of diphtheria tests the duplicate smears were made in each case from a single culture, the growth having been first emulsified in salt solution. These smears, dried on glass slides, were submitted to the laboratories, each of which was allowed to stain the specimens in its own way.

DIPHtheria TESTS—TABLE II.

Lab.	Specimens.				
	1	2	3	4	5
1	—	—	—	—	?
2	+	—	—	—	—
3	—	—	—	—	+
4	+	—	—	—	+
5	—?	—	—	—	+
6	+	—	—	—	?+
7	+	—	—	—	+
8	—	—	—	—	?
9	—Few	—	—	—	+
10	No answer received				
11	—	—	—	—	—

Cultures Nos. 1 and 5 were positive, the others negative. All agree on the negatives, and, again, the chief error is in reporting as negative smears containing diphtheria bacilli.

It is interesting to note that while each laboratory reported one or the other of these cultures

1 and 5, as positive, only three give a positive report on both.

One laboratory did not answer at all, and a troublesome feature in all these tests was the slow progress because of delay in sending reports.

The writer realizes that these tests on diphtheria are too few for a basis for comment, and is planning another series of tests in which the same stained smears will be submitted to all laboratories, thus eliminating discrepancies due to varying cultural conditions or to methods of preparation of the specimens.

It seems evident that positive cultures, containing few bacilli, are apt to be reported negative, especially by the smaller laboratories. Larger laboratories have many advantages which tend to give them greater accuracy. In the first place, the handling of numerous cultures daily keeps the technician in good training, and, secondly, the larger staff allows for the examination of each specimen by at least two observers.

TUBERCULOSIS.

Only one series of specimens has been submitted, and these were smeared and fixed on glass slides, each laboratory doing its own staining.

SPUTUM EXAMINATION FOR T.B.

Lab.	1	2	3	4
1	+	—	—	+
2	+	—	—	—
3	+	—	—	+
4	+	—	—	+
5	+	—	—	+
6	+	—	—	+
7	+	—	—	+
8	+	—	—	—
9	+	—	—	+Few
10	Did not answer			
11	+	—	—	+

Only one mistake is noted here: a case of overlooking the bacilli when they are few. This is the chief error to be expected in this examination.

TYPHOID FEVER.

For this test specimens of dried blood were submitted, the positives from a guinea pig which had been immunized, the negatives from a non-immune pig. Specimens 1, 2 and 5 were negative.

The specimens were submitted in July.

WIDAL TESTS.

Lab.	1	2	3	4	5	
1	—	—	+	—	—	Reported Sept. 8
2	—	—	—	—	—	Reported in July
3	—	?	+	—	—	Reported in July
4	—	—	+	+	—	Reported in July
5	—	—	?	?	—	Reported in July
6	+	—	—	+	—	Reported Sept. 17
7	No report received					

The principal criticism here is in the delay of the reports. One negative specimen was reported as positive by Laboratory No. 6.

GONORRHOEA.

Four smears were submitted to each laboratory, being prepared through the kindness of Dr. Hinton of the Boston Dispensary from four patients, two with positive and two with negative discharges.

GONORRHOEA TESTS.

Lab.	1	2	3	4
1	—	—	+	+
2	—	—	+	+
3	—	—	+	+
4	—	—	+	+
5	—	—	+	+
6	—	+	+	+
7	—	—	+	+
8	—	—	+	+
9	—	—	+	+
10	—	—	+	+
11	—	?	+	+
12	—	—	+	+

One of the negative smears was reported positive by one laboratory and suspicious by another. One great difficulty in gonorrhoea diagnosis is with the proper control of the gram stain. Unless considerable care is used one may decolorize too much, causing gram-positive organisms to appear as gram-negative; or one may decolorize too little, causing gram-negative organisms to appear as gram-positive.

Since one laboratory reported this difficulty overcome by use of Burke's staining method, the formula for this method will, at the request of the other laboratories, be included in the report on technique.

Of these four examinations diphtheria is undoubtedly the most difficult, and the results in the other three series (tuberculosis, typhoid fever and gonorrhoea) are fairly uniform. With diphtheria, however, the discrepancies are very noticeable, and this in spite of the fact that the various workers knew their results were to be compared with those obtained by others.

Since all the diphtheria cultures, with the exception of sets for two laboratories*, were planted on tubes from the same batch of media, and all were delivered to the laboratories within a few hours, it would seem that the cultures should be uniform, yet in one case reported positive by the writer a smear from a duplicate culture was brought to him which showed no diphtheria bacilli.

Probably cultures for diagnosis would have given better results, since the bacilli are apt to be more numerous and of better morphology.

One cannot but feel, however, that diphtheria bacilli have been overlooked in some of these cultures and that some of the technicians need toning up on this examination.

Possibly a frequent comparison of duplicate cultures with other laboratories, or occasional

*One of these laboratories, preferred to inoculate from the culture submitted to its own media; the other made its own cultures from the swabs.

revision of diphtheria slides, staining methods and diagnoses by an expert diagnostician, would be of advantage in establishing a higher precision in diphtheria examinations.

(To be continued.)

TREATMENT OF HUMAN HOOKWORM WITH CARBON TETRACHLORIDE.

NICHOLLS AND HAMPTON (*Brit. Med. Jour.*, July 1, 1922) present the following conclusions as a result of their investigations of treatment of human hookworm infection with carbon tetrachloride:

1. Carbon tetrachloride is an efficient anthelmintic remedy for hookworms.

2. The drug may be administered safely in doses of 10 to 20 minims to children of 3 and 4 years of age, even when they are seriously ill from various causes.

3. It aids the expulsion of *Ascaris lumbricoides* if it is followed by a purgative, but it is not as effective as chenopodium in killing this worm.

4. The drug does not seriously deteriorate on keeping. Many children were given doses of carbon tetrachloride which had been stored in the laboratory for three years.

5. It is more valuable than a chenopodium for campaigns against hookworm disease because—

(a) Patients do not object to its taste.

(b) It is not necessary to precede or follow the administration of it by a purge.

(c) It is more efficient than chenopodium and has not the depressing effects of that drug.

(d) It is much cheaper than any other drug that has been used.

(e) It can be prepared in a high degree of purity, and a chemically pure preparation should always be used.

(f) The person who is being treated can do his usual day's work.

Children when one year of age may be given 10 minims of carbon tetrachloride with safety, and this dose should be increased by 2 minims for each year of apparent age. Thus a child of 10 would receive 28 minims, a youth of 16, 40 minims (2½ c.cm.), and an adult dose should be from 50 to 80 minims (3 to 5 c.cm.), according to the size of the patient.

Finally, chenopodium is soluble in carbon tetrachloride, and a mixture of one part of the former in four of the latter should prove to be efficient for the expulsion of *Ascaris lumbricoides*.

MALIGNANT DISEASE AND LEUKEMIA.

YOUNG (*Edin. Med. Jour.*, June, 1922) presents the results of a further investigation into the etiology of malignant disease and leukemia, including an account of lymphoma and lympho-sarcoma experimentally produced in the mouse.

He believes these investigations provide data in support of the contention that the leukaemic phenomena and lympho-sarcoma are related to one another in regard to their ultimate etiology, and that these states are, on etiological grounds, related to ordinary malignant disease.

[J. B. H.]

JEJUNAL ULCER WITHOUT PREVIOUS GASTRO-ENTEROSTOMY.

RICHARDSON (*Surg., Gyn. and Obstet.*, July, 1922) presents a very thorough and interesting paper on this rather obscure subject. He reports one personal case, one from the records of the Massachusetts General Hospital, and nine cases reported from the literature. He then discusses the probable causes of primary ulcer of the jejunum and states that no sharp line can be drawn between these simple ulcers of the jejunum, which somewhat resemble peptic ulcer of the stomach and duodenum, and similar ulcers occurring lower in the small intestine. Whether these represent a clinical entity or are merely the odds and ends of pathological processes cannot be definitely asserted. No definite etiology can be assigned to them. Since syphilis produces a form of intestinal ulceration which affects the jejunum more readily than the ileum and also has a tendency to cicatricial contraction and perforation, it must be considered a possible cause of ulceration in some of these cases, although definite confirmatory evidence is generally lacking. Two points are of particular importance in future cases: a careful microscopic study of the lesions, including if possible the mesenteric lymph nodes, and a determination of the presence or absence of syphilis.

[E. H. R.]

MEGA-SIGMOID, MEGARECTUM. FECAL BOLUS.

GORDON (*Surg., Gyn. and Obstet.*, July, 1922) reports at length upon these conditions, discussing profusely etiology, prognosis, diagnosis and treatment, the latter of which is distinctly operative; medical treatment entirely failing to relieve either the condition or the symptoms.

[E. H. R.]

RECURRENT DISLOCATION OF THE PATELLA.

MCAUSLAND and SARGENT (*Surg., Gyn. and Obstet.*, July, 1922) report 16 cases of recurrent dislocation of the patella, with a new type of operation for correction of the difficulty. The operation consists in splitting the patella tendon and transplanting its bony insertion in a more lateral position on the tibia. The operation sounds useful and practical.

[E. H. R.]

THE SURGICAL TREATMENT OF UTERINE PROLAPSE. END RESULT IN THIRTY CASES.

HUNDELEY, J. M. and HUNDELEY, J. M., Jr (*Ann. of Surgery*, July, 1922) write as follows.

1. The interposition operation gives better results than any other operation we have used in the extreme cases of uterine prolapse.

2. Of the thirty cases there has been no return of the prolapsa. In one the rectocele returned. She reported that she was sufficiently comfortable, and did not wish to be operated on again.

3. A small percentage of the patients complain of some bearing down and discomfort in the bladder after doing a hard day's work.

4. In cases with marked eversion of the vaginal walls, associated with complete uterine prolapse, a cure can be effected by plicating the cul-de-sac of Douglas, and anchoring it to the posterior wall of the cervix, together with shortening of the uterosacral ligaments.

[E. H. R.]

HISTORY IN TUBERCULOSIS.

H. C. PARSONS (*Canad. M. A. J.*, Vol. xii, No. 4) reports that cases of congenital tuberculosis do occur, but are very rare. Huss accepting forty cases in man, Warthin and Cowie accepting only five. Such children die shortly after birth. There is as yet no satisfactory proof of inherited predisposition. In looking up the family history one should inquire as to the state of health, past and present, of all the family, also of any other permanent or temporary dwellers in the house; in other words, the whole household, especially as to symptoms referable to the respiratory system; even of other families in other than single houses. The personal history should include an enquiry, especially as to 1. Haemoptysis; i. e., a dram or more of blood, as it occurs in from 60 per cent. to 80 per cent. of cases of pulmonary tuberculosis, while tuberculosis is the cause of haemoptysis in from 85 per cent. to 90 per cent. of cases. Osler pointed out that haemoptysis may precede by months any other symptom of pulmonary tuberculosis. 2. Pleurisy; Eichhorst has demonstrated tubercle bacilli in 62 per cent. of cases of "idiopathic" pleurisy; from 30 per cent. to 40 per cent. of such cases are variously reported as eventually developing tuberculosis. 3. Unexplained fever; tuberculosis is the most common cause both in children and adults. In children, a history of recurring fever and vomiting with no evident cause is a common picture in mediastinal tuberculosis. 4. Cervical adenitis; this may be due to other causes, but the resultant scars are useful in helping to establish the diagnosis. 5. Coughs and colds are important if constantly repeated. 6. Loss of weight and fatigue, not only present but past as well.

[A. W. C.]

THE TREATMENT OF SO-CALLED SALIVARIA.

J. A. NUTTER (*Canad. M. A. J.*, Vol. xii, No. 5) discusses sciatica and states that it is in the majority of cases a manifestation of referred pain, and not a neuritis; pain referred from some diseased or injured neighboring joints of the spine or lower extremities, in the following order: lumbar spine, sacroiliac, and hip; other occasional sources of referred pain are: diseases of the uterus and adnexa, posterior urethra and prostatic pelvic inflammations, stone in the kidney, pyeliformis irritation due to flat foot, inflammatory conditions of the lower abdomen, as appendicitis.

In the lumbar spine the greatest offender is gony arthritis, Pott's disease, traumatic conditions, also syphilitic arthritis, typhoid spine and scoliosis being other causes.

In the sacroiliac joint any factor constantly disturbing the body equilibrium will tend in time to cause a chronic strain or relaxation of this joint, such as a pronated foot, the weight of a pregnant uterus, a pendulous abdomen, a short leg or a stiff hip.

In the hip, causes of referred pain in the sciatic nerve are non-tuberculous arthritis, arrested hip disease, all sorts of hip traumatism.

In regard to treatment, when once the exact cause of the referred pain is recognized, the appropriate treatment is at once indicated.

[A. W. C.]

THE CAUSE, SYMPTOMS, AND DIAGNOSIS OF NASAL SINUSITIS IN THEIR RELATION TO GENERAL PRACTICE.

W. S. HUNT (*Canadian M. A. J.*, Vol. xii, No. 7) describes the anatomy of the sinuses, then states that normally the sinuses are sterile even when much infected matter is breathed, until some constitutional disease or obstruction or an attack of influenza cause an infection of their mucosae to occur, leading to long continued trouble. Another cause of infection in the antrum is an infected tooth in close contact with or perforating its floor. Infection of the sinuses is unusual before the age of puberty because the frontal and sphenoid remain undeveloped until the sixth or eighth year. It may, however, complicate scarlet fever, measles, and diphtheria, and should always be suspected in cases of obscure pyrexia. The persistence of a nasal discharge after removal of tonsils and adenoids should always lead to suspicion of sinus involvement, especially if more profuse from one side of the nose. The purulent discharge may work back and reach the larynx, causing a chronic laryngitis and bronchitis, or it may leave through the anterior nares and cause occasionally recurrent facial erysipelas. Acute sinusitis is usually accompanied by headache, tenderness, discharge, and changes in the nasal mucous membrane. The headache is usually a prominent symptom, aggravated by stooping, by alcohol and tobacco, not by reading; has usually a definite periodicity. The discharge is at first watery, soon thick and yellow, may be blown out in great quantity from the nose, but often flows into the nasopharynx, where it may cause an acute otitis or pharyngitis, the latter often mistaken by the patient for tonsillitis. Acute exacerbations resemble simple acute attacks, except that there is likely to be some chronic obstruction in the intervals, excessive nasal discharge, frequent colds, headaches or dizzy spells or ringing in the ears.

There are two forms of non-suppurative sinusitis. One is called vacuum sinusitis and is caused by absorption of the air when the ostium is closed, and is frequent in the frontal sinus and accompanied by severe supraorbital headaches, increased by reading, and associated with tenderness on pressure over the pulley of the superior oblique muscle. The second form affects the ethmoid and sphenoid, is of unknown origin, is very insidious in onset, and may lead to serious results through involvement of the optic nerve. The most frequent symptom is an intractable neuralgia of the trigeminal nerve. Constitutional symptoms are usually mild; in long-standing cases a general run-down condition is frequent, with anaemia and loss of weight and inability to concentrate; or arthritis, recurrent iritis, optic atrophy, and blindness may occur. Orbital cellulitis and fatal meningitis have resulted from sinusitis.

[A. W. C.]

THE MEDICAL CARE OF POST-OPERATIVE ABDOMINAL CASES.

R. D. RUDOLPH (*Canad. M. A. J.*, Vol. xii, No. 7) pleads for closer co-operation of the surgeon with the medical man in the care of post-operative cases. He approves of washing out the stomach before the patient regains consciousness, though this does not help a great deal, as there is still considerable anaesthetic left in the blood. He approves of giving but very little food during the first twenty-four hours, then adding to the diet gradually. If the stomach does not quiet down soon, over 800 calories in 1500 cc. of water can be given in the form of monosaccharides, alcohol, simplest amino-acids, and salts. He quotes two such formulas which he has found useful. In regard to management of the bowels, reasoning from some original experimental work in culturing the blood before and after the giving of cathartics and finding positive cultures in 30 per cent. after, while none had been positive before, he advises holding off giving cathartics except after the careful consideration of a medical man. Enemata are less objectionable and mineral oil still less.

In regard to pain, if the surgeon cannot remove the cause, then morphia should be given, not codein, and not combined with atropin, as there is already frequently a distressing dryness of the mouth and throat. Slight thirst may be relieved by washing the mouth with warm alkaline solutions, or by chewing gum. Water may have to be given by rectum, subcutaneously, or intravenously, avoiding acute oedema of the lungs by the last method. Nausea and vomiting may be due to several causes; if due to the anaesthetic, free drinking of warm water with consequent washing of the stomach may be sufficient, lavage may be needed, or cocaine gr. $\frac{1}{4}$ with or without mxxv of 1/1000 adrenalin solution; if from acute dilatation of the stomach, a rare condition, lavage and pituitrin $\frac{1}{2}$ -1 cc. is of value; if of the toxic type, channels of elimination should be flushed, and glucose and soda solutions given subcutaneously or intravenously. The neurotic type is helped with large doses of bromides or with chloral and bromides by rectum. The stomach tube often has powerful psychic influence. Hiccough is best helped by atropin hypodermically or by chloralate by mouth. Tympanites may yield to hot applications and turpentine enemata, or molasses and milk enemata. Large doses of digitalis by rectum act in some obscure way to prevent or cure this condition, also to lessen the respiratory complications. Pituitrin or adrenalin may help, but must be used with caution as they raise blood pressure and may overstrain a flabby heart.

[A. W. C.]

EYE CONDITIONS IN PREGNANCY.

CHARLES GRAEL (*Canad. M. A. J.*, Vol. xii, No. 7) describes both the common and rare eye conditions occurring in pregnancy; of these, the more important are the following: the eyelids may be strikingly pigmented. Styes are common during the early months and again during lactation. There may occur phlyctenular disease, and failure of accommodation may occur from weakness of some of the eye muscles, causing headache, diplopia, etc.; also frequently paresis of the ciliary muscles occurs, often suddenly, most commonly during early lactation, with consequent very troublesome blurring. The emotional influences of pregnancy and labor may be manifested by various eye symptoms, such as an exaggerated dis-

comfort on using the eyes, photophobia, narrowing of the visual fields, and occasionally absolute blindness, all with no evidence of ocular disease. Non-syphilitic iritis may precede labor. Eye conditions associated with albuminuria form the most serious problem, occurring at any period, but most commonly late; the most important are affections of the optic nerve and retina and the visual changes due to intracranial lesions. Often there is oedema of the lower lids when no oedema occurs elsewhere in the body, but permanent oedema occurs here only when the ankles, legs, and serous cavities are involved. A detailed account of the ophthalmoscopic findings is given. As to prognosis, sight is most impaired when the optic nerve is affected; slight evidence of disease in the retina and nerve head with markedly affected vision leads to a poor prognosis, probably due to haemorrhages into the nerve trunk with resultant permanent damage. Uraemic blindness or amblyopia occurs as a part of the uraemia, develops rapidly, and the ophthalmoscopic appearances are negative even in cases of complete blindness. The pupil in purely uraemic cases is usually dilated, but may be contracted, but the light reflex is retained. The loss of the light reflex points to pathology in the optic nerve or primary optic ganglia. The blindness in uraemia is due to oedema or circulatory disturbances in the optical cortex of the occipital lobes. The author quotes an obstetrician as advising prompt emptying of the uterus in cases of albuminuric retinitis that is getting worse in spite of treatment, while the ocular complications of eclampsia, unless the case is one due to chronic nephritis associated with pregnancy, do not call for this interference.

[A. W. C.]

THE VALUE OF NEUROLOGICAL EXAMINATION IN SYPHILIS.

R. HOYT (*A. J. Syphilis*, Vol. vi., No. 2) advises most careful neurological examination of syphilitic and suspected syphilitic cases, because it is well recognized that active neurosyphilis in an insidious form may be present in any case in which the diagnosis of syphilis has been established, and that many forms of the disease which are controllable at first, later become uncontrollable. To detect neurosyphilis during its early or formative stages, a complete neurological and serological examination is essential, because the disease process may occur in any part of the nervous system and thus produce any symptom, functional or biochemical. As it is not so much the disease itself as it is the part of the nervous system involved that determines the seriousness and course, the following is suggested as comprising a complete neurological examination.

1. An objective examination of all functions of sensibility (both general and special), followed by an inquiry as to present and past subjective sensory disturbances.

2. An objective examination of the various forms of motility (both of the appendicular musculature, and of the musculature of such special mechanisms as the eyes, jaws, face, tongue, pharynx and larynx), followed by an inquiry as to present subjective motor disturbances.

3. Inquiry and examination as to the functional status of the involuntary mechanisms, the vasomotor, gastrointestinal, genitourinary, and secretory systems.

4. An objective examination of the special functions of the cerebral cortex (stereognosis, speech, praxis, etc.), and an inquiry as to such organic disturbances as convulsions, loss of consciousness, etc., and as to such psychic disturbances as are characteristic of the neuroses, psychoses, and borderline states.

5. An objective examination of the kinesthetic function, namely, the reaction of the nervous system to labyrinthine stimulation as induced by rotary movement.

By employing this method of examination as a routine, many cases of hitherto unsuspected cases of neurosyphilis are revealed, some with symptoms characteristic of the disease, but more with symptoms not characteristic but consistent with syphilis, the true connection with syphilis being made by the spinal fluid examination. This neurological examination should be made at intervals during the course of the disease; the author considers such repeated examinations as imperative.

[A. W. C.]

COMPARATIVE CLINICAL OBSERVATIONS ON INVOLVEMENT OF THE NERVOUS SYSTEM IN VARIOUS PHASES OF SYPHILIS.

J. H. STOKES and A. R. McFARLAND (*Am. J. of Syphilis*, Vol. vi., No. 2) discuss a group of cases from the point of view of the central nervous system. Their conclusions are in brief as follows: In very early untreated secondary cases the proportion of positive findings may reach 60 per cent. to 70 per cent., falling to 40 per cent. within the first six months, and to 25 per cent. to 30 per cent. after the first year or two. Treatment of these cases within the first year, if intensive, causes a rapid and marked response in many cases; this is the most hopeful time for improvement. The first serological sign of involvement is a rise in cell count, which should best be regarded in doubtful cases as syphilitic, though it might be due to other conditions; the next is globulin content; finally the positive Wassermann reaction. Since symptoms and signs are to be regarded as late manifestations and since there is no parallelism between early symptoms and spinal fluid findings, spinal puncture should be done routinely. Spinal puncture should not be done in early cases without a preliminary sterilization of the blood stream by one or two arsenphenamin injections to prevent a possible transfer of organisms to the meninges, but a test early in the course of arsenphenamin will give valuable aid, and should be done before substituting mercurial treatment for arsenphenamin in the first course. Patients whose spinal fluid is normal at this time, usually continue so through all stages; about 40 per cent. to 50 per cent. are of this type. This proportion can be increased by 50 per cent. to 75 per cent. further by effective treatment during the first two years of the disease; this is, then, the vital period of the disease from the therapeutic standpoint. A proportion varying from 5 per cent. to 8 per cent. in early, and from 14 per cent. to 41 per cent. in late syphilis will present negative Wassermann reactions on the blood and abnormal spinal fluids. As the syphilitic infection progresses from the early to the late stages, neurosyphilitic changes assume increasing importance. To a surprising degree, neurosyphilis complicates or underlies the internal medical aspects of the disease. In its detection, the examination of the spinal fluid may exceed any other procedure in diagnostic importance and proportion of positive results. In the diagnostic work of the Mayo Clinic a proportion of only 45 per cent. to 50 per cent. positive Wassermann reactions on the blood as compared with 60 per cent. to 70 per cent. positive reactions on the spinal fluid of syphilitics seems to be the rule.

[A. W. C.]

EPIDEMIA OF THE TENDON SHEATHS.

STRAUSS, A. (*Surgery, Gynecology and Obstetrics*, August, 1922), reports as follows:

This condition is a rare disease, as shown by the fact that there are only eighteen cases reported in

the literature. There are two distinct types,—lipoma arborescens and lipoma simplex. Clinically, they may be considered together because the symptoms, signs, locations, treatment, and prognosis are practically the same. In fact, preoperatively, they have seldom been distinguished.

The etiology is unknown. Some authors have tried to attribute these growths to a former tuberculous process, and Kummer concluded that they do not belong to the class of tumors but are the result of chronic inflammation. The author, however, believes that to argue that the formation of a fatty deposit is the end-result of an inflammatory process is not convincing, and believes that they are more liable to be the result of simple trauma or of unknown origin.

Lipomata of tendon sheaths are composed of fatty tissue without any evident capsule other than the tendon sheath itself, to which they are so intimately attached that the sheath must be sacrificed in removing the growth.

The author reports seventeen cases with operation and end-result.

[E. H. R.]

SOME EXPERIENCES WITH THE "MELTZER-LYON" TEST IN GAIL-BLADDER DISEASE.

CUTLER, E. C., and NEWTON, F. C. (*Surgery, Gynecology and Obstetrics*, August, 1922), make the following conclusions:

The "Meltzer-Lyon" test is based upon the application of the law of contrary innervation to the biliary system. There is no proof of this at present.

It is our opinion that the specimens of bile obtained are the result of siphonage.

The test cannot be depended upon for diagnostic purposes even when accurately performed.

[D. H. R.]

HYPERPLASIA OF THE RUDIMENTARY LYMPH NODES OF THE PROSTATE.

FUKASE, N. (*Surgery, Gynecology and Obstetrics*, August, 1922), draws the following interesting and seemingly practical conclusions from his work. It is believed that it has formerly been not understood that the region of the prostate gland was involved in such diseases as Hodgkin's, lympho-sarcoma, and leukemia.

Small, primitive, or rudimentary lymph nodes occur normally throughout the prostate in the form of very small aggregations of lymphocytes located beneath the glandular and duct epithelium, most marked toward the outlets of the ducts. They are analogous to the rudimentary lymph nodes found in other organs, such as the liver, kidneys, uterus, etc.

Hyperplasia of these rudimentary lymph nodes of the prostate occurs chiefly in chronic hyperplastic prostatitis and in primary carcinoma of the prostate. In both conditions, the hyperplasia is essentially an inflammatory one due to chronic infection, or irritation, and possesses the same significance that such hyperplasias have in other parts of the body.

In the absence of chronic inflammation, a hyperplasia of the primitive lymph nodes of the prostate occurs in the lymphatic constitution, and may be found also in other generalized diseases of the lymphoid system, as Hodgkin's disease, lymphocytoma, and leukemia.

In both the inflammatory and non-inflammatory hyperplasias well developed germinal centers may be produced in the hyperplastic node. Other evidences of functional activity by these hyperplastic nodes are shown in the metastasis of pigment, tubercle bacilli, and carcinoma cells to them.

CREATINURIA AND GLYCOSURIA IN MYASTHENIA GRAVIS.

WILLIAMS and DYKE (*Quarterly Journ. of Med.*, July, 1922) report observations on four cases of the above disease,—three women and one man. On a creatin-free diet they found creatin in the urine in all, in one case amounting to one-half gram in 24 hours. The addition of measured amounts of creatin to the diet resulted in the excretion of one-third to one-half of the added creatin in the urine. (Normally no creatin is excreted in the urine.) The creatin metabolism is therefore defective in this disease of the voluntary muscle. In two cases pieces of muscle were excised and analyzed for creatin, and amounts somewhat below the normal were found.

The occurrence of traces of sugar in the urine led the authors to investigate the sugar tolerance in three patients, in all of whom it was found to be diminished. It is interesting to note that, while all responded in a normal manner to the ingestion of 50 grams of glucose, the administration of 100 grams resulted in a marked rise of the blood sugar and in glycosuria. The administration of levulose, however, did not raise the blood sugar level, indicating that the liver function was normal in this respect.

The authors are inclined to explain the defective carbohydrate metabolism as due to deficient storage of sugar in the muscles, and to link it up with the abnormal metabolism of creatin.

[W. T.]

LOWERED BASAL METABOLISM IN DISORDERS OF THE ENDOCRINE GLANDS.

H. G. HILL (*Quarterly Journ. of Med.*, July, 1922) makes a welcome contribution to endocrinology, for he reports facts instead of hypotheses.

He measured the basal metabolism by the Douglas bag method, using the DuBois standards and method of calculating surface area.

Five cases of hypopituitarism showed a marked lowering of the basal metabolism, while three of four cases of acromegaly showed an increase, likewise a case of dyspituitarism.

Of great interest are his observations on borderline cases with symptoms of overaction of the parasympathetic (autonomic) system. Thus six out of 20 cases of nocturnal enuresis showed definite lowering of the metabolism associated with minor physical signs suggestive of endocrine deficiency, and all were cured or much improved by thyroid extract.

In addition, six cases of lowered metabolism are reported, occurring in cases with symptoms of vagotonia, or increased irritability of the parasympathetic system, viz., intestinal colic, mucons colitis, asthma, attacks of profuse sweating, and fainting fits. Five of these were treated with thyroid extract with much benefit.

He attempts to explain these phenomena by the connection of the thyroid with the sympathetic system. It has been shown that stimulation of the sympathetic is equivalent to inhibition of the parasympathetic, and *vice versa*, so that a decrease of thyroid activity would be likely to result in increased irritability of the parasympathetic. In the case of enuresis, the same explanation would apply, for it is known that stimulation of the parasympathetic excites emptying of the bladder.

Twelve normal controls showed a slight increase in the basal metabolism, varying from +4 to +13 per cent. This makes his findings of lowered metabolism in disease still more worthy of credence.

[W. T.]

THE BOSTON Medical and Surgical Journal

Established in 1828

Published by The Massachusetts Medical Society under the jurisdiction of the following-named committee:

For three years WILLIAM H. ROBEY, JR., M.D.
ROGER I. LEE, M.D.
ROBERT B. OSGOOD, M.D.
For two years JAMES S. STONE, M.D.
HORACE D. ARNOLD, M.D.
CHANNING BROTHINGHAM, M.D.
For one year HOMER GAGE, M.D., *Chairman*.
EDWARD C. STREETER, M.D.
EDWARD W. TAYLOR, M.D.

EDITORIAL STAFF.

WALTER P. BOWERS, M.D., *Managing Editor*.
GEORGE G. SMITH, M.D., *Assistant Editor*.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

ANOTHER LETTER FROM MR. NUNN.

Even at the risk of wearying our readers the JOURNAL has given space to another communication by Mr. Henry D. Nunn. So far as his argument goes everybody would agree that the average person instinctively revolts at any surgical operation however trivial. The average person revolts at having a tooth extracted, but he suffers the annoyance for the benefit to be obtained. Any well-balanced individual would not submit to a hypodermic injection except under the expectation of benefit. Thousands upon thousands of persons revolt at having more serious operations performed but adopt the resources of surgery because the end justifies the means: so all of us would prefer to give up vaccination if we did not believe in its efficacy, but vaccination has been found to be potent in controlling smallpox, hence we use it for ourselves and for those under our control. According to modern conceptions, several diseases may be prevented through the creation of immunity and however the immunity is conferred we employ the means, provided the procedure has a minimum risk. We believe in requiring vaccination of those who participate in the benefits of school life, for without acquired immunity, smallpox would be a common disease exposing the multitude and laying a heavy economic burden on society.

When Mr. Nunn speaks of putrid matter he

tries to carry the impression that vaccine is especially dangerous, whereas the vast majority of persons sooner or later through accidental means, are infected with more virulent germs than those found in vaccine without developing serious after-effects. Vaccine, as now prepared, seldom does more than develop a mild reaction. It is very likely that careful breeding of vaccine-virus, through successive generations in the calf, develops a strain which is potent for protection but does no lasting damage to the human subject. The records of this State seem to prove this assertion.

But Mr. Nunn's heavy artillery consists of his comment on the suggestion of submitting children to contact with smallpox for the purpose of comparing the relative number of cases of smallpox among the vaccinated and the unvaccinated. He then branches off into a suggestion that there is a widely entertained suspicion that those engaged in medical research are none too respectful of fundamental human rights of inmates of orphanages, hospitals and asylums. Let Mr. Nunn cite examples of inhumanity on the part of physicians and the medical profession would be in the field as early as anyone to correct abuses. Men possessed of scientific minds have human instincts quite as well developed as any of our people and will go as far and endure as great sacrifices as any of the heroes of history who have surrendered life for the benefit of others. Medical men have not, in recent times, resorted to the experiment of submitting children to exposure of smallpox and they never will again. In the first place they do not need to, for exposure has occurred too often and the results observed.

The Medical Liberty League would do it through the elimination of the compulsory feature of the law, and if they can ever have their way they will do it, for they advocate the omission of compulsory vaccination and that means that large groups of school children would grow up unprotected and in the presence of smallpox would be infected. The history of smallpox shows that it spreads among those not protected by effective vaccination, and without the compulsory feature many would not secure protection, for it is the tendency of many people to make no provision for protection until the menace is demonstrated.

So much space has been given to this discussion that we must now close it. The subject will be before our legislature from time to time and we shall respectfully refer Mr. Nunn to that arena.

THE SPAHLINGER TREATMENT FOR TUBERCULOSIS.

The Associated Press item in the Richmond Times reports that the British Red Cross has decided to purchase the vaccine treatment

originated by Henry Spahlinger of Geneva, and the contract has been signed. A number of American patients are now under treatment.

In an editorial in the *Journal of Laboratory and Clinical Medicine*, the statement is made that the treatment "utilizes either or both of two therapeutic principles, depending on the nature of the infection." In acute cases passive immunization, with special immune sera, is employed, and in chronic afibrile cases, active immunization with special antigens is practiced.

After a somewhat detailed explanation of the theory and application of the sera employed, the following statement appears:

"The illustrative cases reported are eight in number and are characterized by some vagueness in description. This may be because the article is in the nature of a general summary. Nevertheless it is regrettable. Three roentgen plates are shown, but they are on three different patients, so that no comparison can be made."

If the decision of the British Red Cross is founded on a report of eight cases, one may question the quality of judgment exercised. If the claims made for this treatment are found to be sustained, the action will be approved. The medical profession, however, may be justified in watchful waiting for the present.

THE RAT MENACE.

The Public Health Service and Massachusetts State Health Department are concerned in the possibility of plague extension to this country. Dr. Louis L. Williams of the U. S. Public Health Service, in association with H. C. Mosman of the Massachusetts State Department of Health, have made a study of our conditions. An analysis of the situation shows that there are sixteen municipalities in Massachusetts with water fronts used more or less for shipping. The docks along our water front are especially adapted to the propagation of rats, for the construction affords shelter and the food supply is abundant. Boston and its contiguous water fronts should, according to the minimum estimates, furnish about sixty thousand rats. Lynn over two thousand, Salem about four thousand, Beverly about three thousand, Danvers over one thousand, Peabody over one thousand, Newburyport over one thousand, Gloucester five thousand, New Bedford and Fairhaven about six thousand, Fall River about six thousand, Buzzards Bay over a thousand, Quincy over a thousand and Plymouth five thousand.

These places could be made to yield a catch of probably not less than one hundred thousand rats, but even then a campaign would have to be followed by rat proofing of the buildings and regular campaigns for extermination.

We are living under a false sense of security, because, up to the present time, no plague infected rats have been discovered on our coast-

line, from Florida to Maine, and with the exception of Norway, this is the longest coast-line that has been free from plague. According to the expectation of experts, this favorable condition will not long exist.

The Massachusetts Legislature has not been inclined to regard the situation as sufficiently serious to warrant the expenditure of much money in the destruction and study of rats, although the facts were presented at the last session. The control of rodent infestation is quite well understood and should be presided over by experts. To all who are interested, the underlying facts and the recommendations may be found in Public Health Bulletin, No. 121, under date of May, 1922.

DIPHTHERIA.

In the Public Health Reports for August 18, Dr. J. W. Schereschewsky presents a paper, revised by Dr. R. E. Dyer, on this disease. The treatise is concise, covers the whole problem involved in the etiology, pathology, clinical features and treatment of the disease.

If every medical student could be made to memorize every statement made in this article, the coming generation would be benefited to a great extent. Also, if every physician who may be likely to have to deal with the disease would supply himself with a few copies to be loaned to parents, the campaign for prevention would receive an impetus. Incidentally the propaganda of the anti-vivisectionists would have less hold on the public mind if the laity could be shown that the efficient use of antitoxin on the first day of the disease, practically reduces the mortality to zero. The only objection that the antis could bring forward is found in the frank statement that horse serum is not always well borne by a small number of susceptibles.

There is one danger, to a small percentage of the medical profession, involved in widespread information of this sort: for if a doctor should fail to make an early diagnosis, or to apply the remedy, it is conceivable that a suit for damages might result, and unless an adequate excuse could be given, a jury, furnished with the known facts, might render an unpleasant verdict.

MEASLES.

According to W. C. Rucker, U. S. Public Health Service, about 10,000 children died of measles in this country last year. This does not include many deaths from the sequelae of measles such as broncho-pneumonia and tuberculosis. The occasional resulting eye and ear disabilities also add to the importance of this disease from a public health standpoint.

Epidemics usually increase in number with

the progress of the school year. The greatest numbers of fatal cases occur in the period from two to five years of age. Contrary to the ideas of a generation ago, the transmission stage rarely extends beyond the febrile period. Testimony indicates that the infection may be carried by a third person and the possibility of second or even third attacks is recognized.

Since the disease is eminently contagious and children may be exposed during the coryza stage before the disease is recognized, parents can be of great assistance to public health officials if due care is exercised. Without this co-operation the boards of health are handicapped in dealing with this menace. The common indifference should give way to intelligent management of the early indications of coryza in childhood.

THE LAWFUL POSSESSION OF HYPODERMIC SYRINGES.

A REPUTABLE and prominent practitioner in this state desires to place in the hands of a patient a hypodermic syringe for the purpose of administering a remedy which is not a narcotic drug. This remedy is a simple glandular product which has been recommended in the treatment of a disease. The Massachusetts law definitely prohibits the possession of a hypodermic syringe under the circumstances outlined above. The text of the law is as follows:

CHAPTER 94. GENERAL LAWS.

SECTION 209. No person, not being a physician, dentist or veterinarian registered under the laws of this commonwealth or of the state where he resides, wholesale druggist, manufacturing pharmacist, registered pharmacist, manufacturer of surgical instruments, official of any government having possession of the articles hereinafter mentioned by reason of his official duties, nurse acting under the direction of a physician, employee of an incorporated hospital acting under the direction of its superintendent or officer in immediate charge, or a carrier or messenger engaged in the transportation of such articles, shall have in his possession a hypodermic syringe, hypodermic needle, or any instrument adapted for the use of narcotic drugs by subcutaneous injection. No such syringe, needle or instrument shall be delivered or sold except to a registered pharmacist, physician, dentist, veterinarian, wholesale druggist, manufacturing pharmacist, a nurse upon the written order of a physician, or an employee of an incorporated hospital upon the written order of its superintendent or officer in immediate charge. A record shall be kept by the person selling such syringe, needle or instrument, which shall give the date of the sale, the name and address of the purchaser and a description of the instrument. This record shall at all times be open to inspection by the department of public

health, the boards of registration in medicine, veterinary medicine, and pharmacy and the board of dental examiners, authorized agents of said department and boards, and police authorities and police officers of towns. Whoever violates any provision of this section shall be punished by a fine of not more than one hundred dollars or by imprisonment in a jail or house of correction for not more than six months, or both.

Any intelligent person could be taught to use a hypodermic syringe with safety, but under the law a medicine can only be administered subcutaneously by the doctor or a nurse. In some cases the circumstances of the patient call for economy, and if a remedy can be applied without undue expense, some patients should be relieved of the necessity of having it administered by a doctor or nurse.

At the time of the passage of the law relating to drug addiction, the syringe was not so generally employed in non-narcotic treatment as it is now, and is likely to be in the future, and at the legislative hearings no one suggested the possibility of subcutaneous medication other than applying to the narcotic drugs. If the treatment of some chronic constitutional diseases is to be subcutaneous medication, it may be wise to give the physician power to delegate the technical application to some person other than a nurse in some cases.

The Massachusetts law has imposed restrictions exceeding those found in the Harrison Act. Our Committee on Legislation may find it advisable to suggest some change.

NEWS ITEMS.

WORCESTER DISTRICT MEDICAL SOCIETY.—The first regular meeting for the year 1922-1923 was held Wednesday, Sept. 13, 8.15 p. m., at the University Club Rooms, 377 Main street. Program: Classifying Our Cardiacs, Dr. G. M. Albee, Worcester; lantern slides of Electrocardiograms were shown.

The discussion was opened by Dr. S. A. Levine, Peter Bent Brigham Hospital, Boston.

NOTES FROM THE BERKSHIRE DISTRICT.—On August 31st the Berkshire District Medical Society held a very interesting and well-attended meeting at the Curtis Hotel in Lenox. The State president, Dr. Bartol, was with us, as was also Dr. Torr Wagner Harmer, who spoke on "Office Surgery," and was extremely interesting.

Dr. Henry Colt has recently returned from a vacation trip spent in Alaska.

Dr. B. W. Paddock is again at work, after being confined with illness for a few days.

Dr. and Mrs. Nathan Finkelstein have a new daughter.

Dr. J. A. Sullivan recently suffered the loss of his State Registration certificate. While he was out at dinner someone entered his office and carefully removed it from the frame and carried it away. Nothing has been heard from it since.

At the recent meeting of the Berkshire District Society the resolution offered by Dr. Croft of the Franklin District was rejected by a unanimous vote.

APPOINTMENT OF DR. GEORGE H. BIGELOW.—Beginning August first, Dr. George H. Bigelow began work under his appointment as Director of the Cornell Clinic, First avenue and Twenty-seventh street, New York city.

Dr. Bigelow is the son of Dr. Enos H. Bigelow of Framingham.

REMOVAL OF LOCATION OF THE F. H. THOMAS CO.—On September 4th the F. H. Thomas Company of Boston announced their removal from their old location at 691 Boylston street to 208 Newbury street, near Exeter street, where they now occupy an entire four-story building containing over eleven thousand square feet.

Their new building will admirably accommodate their business, which had outgrown their old quarters. The first floor is devoted to the display and sale of surgical instruments, which are attractively arranged in classified groups, a sample of each item being displayed. Most of the medical supplies, together with medical books, are easily available on this floor, so that customers may be promptly served. The heavier hospital and physicians' office furniture, sterilizers, scales, etc., are located on the second floor. Part of the floor has been partitioned into three small rooms, which are equipped as typical doctors' offices for general and special practice. The front part of this floor is devoted to the display and demonstration of microscopes, microtomes, and other laboratory equipment. Their orthopedic department, including three large, well-lighted fitting rooms, together with an attractive and spacious waiting room, is placed on the third floor. Convenient to this is their work-shop, where special orthopedic apparatus is fabricated. Stock rooms occupy the remainder of the third floor. The general and private offices are on the fourth floor, which is well lighted by means of roof lights. Laboratories and sewing rooms occupy the rest of this floor, in which are manufactured the many products of the F. H. Thomas Company.

The building itself is thoroughly modern, served with an automatic elevator, and contains a large, high-studded basement, which is used for shipping and storage. It is conveniently located, scarcely three hundred feet from their old place of business.

The F. H. Thomas Company will continue to operate their branch store near the Harvard Medical School, where a full line of text books and supplies is carried for the convenience of

the students and nurses in that district. On the top floor of their branch store is situated their instrument shop, where repair work and special instruments are made.

A cordial invitation has been extended by the F. H. Thomas Company to call on them and inspect their new quarters.

THE SPRINGFIELD ACADEMY OF MEDICINE.—The regular meeting was held Tuesday, Sept. 12, 1922, at 137½ State street, at 8.30 p.m. Dr. Channing Frothingham of Boston read a paper on "Heart Irregularities."

The list of speakers for the coming year includes Drs. Alexis Carrel, J. W. Williams, W. S. Thayer, and others of equal note.

FRANKLIN DISTRICT MEDICAL SOCIETY.—The regular bi-monthly meeting was held at the Welton, Greenfield, Tuesday, Sept. 12, 1922, at 11.15 a.m. Dr. E. H. Trowbridge of Worcester, Mass., read a paper on "Medical Ethics."

DR. WM. D. WHEELER has returned from his studies at New York hospitals, and resumed his practice at 360 Commonwealth avenue.

BEQUESTS TO HOSPITALS.—In the will of Arthur B. Emmons, late of Newport, it is provided that the Newport Hospital and the Children's Hospital of Boston are each to receive \$25,000.

Miscellany.

CONFERENCE OF TUBERCULOSIS AND PUBLIC HEALTH SOCIETIES.

A CONFERENCE of the secretaries of Massachusetts tuberculosis and public health societies was called for Friday and Saturday, September 8-9, at Hotel Victoria, Boston, which was well attended by representatives of the city and county organizations. The main purpose of the meeting was not medical, but rather to organize the coming Christmas seal sale on a broader basis than heretofore. Mr. R. V. Spencer, Executive Secretary of the Massachusetts Tuberculosis League, was Chairman, and the sessions consisted of round table discussions instead of set papers. Mr. Basil G. Eaves, Campaign Secretary of the National Tuberculosis Association, spoke of the general needs of organization, while Mr. Ernest D. Easton, Executive Secretary of the New Jersey Tuberculosis Association, one which had had an unusually successful sale the past two years, outlined his methods. Miss Bernice W. Billings, Executive Secretary of the Boston Tuberculosis Association, told of the good work at the Prendergast Preventorium for Children, and noted the progress of the Modern Health Crusade, and the field nurses of the

League, and Miss M. Alice Gallagher, Executive Secretary of the Norfolk County Public Health Association, spoke of work in rural Massachusetts, in which a serious effort is under way to improve conditions. Dr. Edward O. Otis spoke of the distribution of tuberculosis. Mr. Speneer presented in his introductions of the successive speakers a deal of interesting information on ratios, variety of work, needs of different movements undertaken by the League, etc., and Mr. John Ritchie and Mr. Roscoe W. Vining discussed informally publicity methods and organization for the Christmas seal sales, respectively.

REPORT OF THE HAVERHILL BOARD OF HEALTH FOR 1921.

The conspicuous features outlined are as follows:

1. Lowest death rate in the history of the city, 12.17 per 1,000 of population.
2. Average of the 667 decedents, 47 years, 8 months, the maximum longevity for 42 years.
3. Increase in the average age of decedents from 30 years, 10 months in 1880, to 47 years, 8 months in 1921, a gain of 54 per cent.
4. Infant mortality rate of 1.56 per 1,000 of population with 86 decedents under 1 year of age.
5. One death from diarrhoea and enteritis of children under 2 years of age, with a rate of 1.82.
6. Only 114 deaths of children under 5 years of age, the percentage of 17.09 to total mortality being the lowest ever known.
7. Unusually low percentage of 5.71 for 68 decedents born during calendar year, as compared with births.
8. One death from typhoid fever with a rate of 1.82.
9. Smallest number of deaths from tuberculosis, 42, since that disease was made reportable.
10. Lowest death rate from preventable diseases, 1.40 per population, with 77 deaths.
11. Average age of 38 years, 6 months for decedents during the past 42 years, with an average death rate of 15.97 per 1,000 of population for that period.

The mortality rate of 12.67 is considered by the members of the Board most remarkable, confirming the belief that Haverhill people are becoming more and more interested in public health matters through our educational efforts and are, in consequence, taking greater care of themselves and paying more attention to their health by frequent physical examination, thus prolonging their lives.

Haverhill, when the Board of Health was first created in 1880, had 350 deaths with population of 18,506, the rate that year being 18.02 and the average age of the 350 decedents being 30 years and 10 months.

The population of Haverhill, as estimated by

the Federal and State Census bureaus for January 1, 1921, was 54,817.

This estimated population gives a rate of 12.17 per 1,000, the lowest death rate in the history of the city, with 667 deaths, exclusive of stillbirths, and a new high mark was attained last year in longevity, with the average age of the decedents 47 years and 8 months.

The highest death rate for Haverhill was 21.08 in 1886, when there were 481 deaths with a population of 22,818, the average age of decedents that year being 28 years, 9 months. Three years previously the average age of decedents was 26 years, 11 months, the lowest point ever reached.

A review and study of the mortality statistics as compiled by this Department, discloses that there have been 23,553 deaths since 1880, the yearly average being 560, this giving an average rate of 15.97 per 1,000 of population and the average age of decedents having been 38 years, 5 months.

It is interesting to point out in this connection that since 1900, when Health Departments were first changed from Committees on Nuisances to take up the advocacy of preventive medicine, the death rate has been less than 15 per 1,000 and in only one year, 1906, was the average age of decedents less than 40 years.

It is also most notable that while the population of Haverhill has almost trebled since the Board of Health was first established in 1880, the death rate has decreased about 33 per cent. while the span of life of those who have passed on has increased about 54 per cent.

The 1921 mortality statistics disclose that two-thirds of the 667 who died were over 40 years of age and of that number 185, or 27 per cent. of the total number of deaths, lived beyond threescore and ten. Another feature for 1921 was that 10 of the decedents were over 90 years of age, one of whom lacked a few months of becoming a centenarian.

It is singular that one-sixth of the deaths were children under 5 years of age and another sixth from 5 to 40 years, the 30-40 age group numbering 44, while in the infant mortality group of under one year, there were 86, 27 of whom lived less than a day.

The 114 children under five years, who died within the past 12 months, gave a percentage of 17.09 to total mortality, this being the lowest rate within the past 42 years. The decedents under 1 year numbered 86, with a rate of 1.56 per 1,000, and of that number 68 were born during the calendar year with a rate of 5.71 as compared with the total number of births.

Deaths from diarrhoea are generally regarded as the real index of infant mortality and we feel pleased in calling attention to the fact that during the past year there was only one death from that cause among the 96 children who passed away before they reached their second

birthday, with a rate of 1.82, the lowest in the history of our city.

Haverhill was free from any unusual outbreak of diseases in the past year, the total number of deaths from preventable diseases having been 77, with 47 deaths from pneumonia, of which 28 were lobar, and 42 deaths from tuberculosis. This gave a rate of 1.40 per 1,000 of population, another record mark in the work of the Health Department.

The morbidity and mortality figures for the past two years, on reportable diseases, were:

	1921		1920	
	Reported	Deaths	Reported	Deaths
Chicken-pox	214		69	
Diphtheria	239	10	247	8
German measles	1		38	
Infection of eyes	8		24	
Measles	25		1,011	8
Mumps	112		155	
Scarlet fever	135	2	81	1
Tuberculosis	98	47	117	57
Typhoid fever	9	1	12	
Whooping cough	209	5	98	3
Anterior poliomyelitis	19	2	25	9
Lobar pneumonia	118	28	162	44
Cerebro-spinal meningitis	2	2	3	2
Influenza	62	3	1,413	49
All other	32		3	
Total	1,286	101	3,469	181

The number of deaths from diphtheria as will be seen from the table, was unusually large, this fact being more clearly seen if reference is made to the table of deaths from that disease for many years past. The case history of the 10 decessents shows that five had complications of myocarditis and two were laryngeal, and these with the three others had been ill for from three to five days before the cases were reported.

This department has already arranged for the introduction of the Schick test, a harmless and simple test to determine susceptibles and immunes, and we hope to enlist the co-operation of parents so that within a short time, diphtheria will be reduced to a minimum, if not entirely wiped out, especially among school children and those of pre-school age.

This report is a model of concise and complete information of the health conditions and problems of Haverhill.

LEGISLATIVE MATTERS.

NATIONAL HEALTH LEGISLATION—REPORTED BY THE NATIONAL HEALTH COUNCIL.

The Tariff and Public Health. H. R. 7456. The Senate passed the tariff bill on August 19th. The bill has gone to conference, as the Senate made numerous changes, but it is expected that a conference report will be adopted about September 15th.

The Senate made notable changes in the tariff

bill regarding synthetic medicinals and chemicals, about which much controversy has existed. While efforts to continue the embargo provisions of the present emergency law did not succeed, prohibitive duties were incorporated, which are regarded as equivalent to an embargo. It was asserted that the manufacture of synthetic drugs and medicinals from coal tar products in the United States during the war could not be continued against German competition, unless amply protected by tariff duty. Among the products in this category are, aspirin, novocaine, benzoic acid, phenol and many other similar coal tar products. Such articles will bear a tax of 75 per cent. ad valorem and an additional 10½ cents per pound when unfinished. They will be taxed 90 per cent. ad valorem and an additional 10½ cents in a finished state. The bill places a 25 per cent. duty upon chemicals, drugs and medicinals, whether dutiable or free, when they are imported in capsules, tablet or similar forms.

Defining Butter and Fixing a Standard for Butter. S. 3858. Favorably reported to the Senate by the Committee on Forestry and Agriculture, August 19, 1922, and placed on the Senate Calendar.

This bill describes butter as the food product usually known as butter, made exclusively from milk or cream, or both, with or without common salt and with or without coloring matter, and containing not less than 80 per centum, by weight, of milk fat.

MATTERS NOT PREVIOUSLY CONSIDERED.

The Coal Situation and Congress H. R. 12-472. Introduced by Representative Winslow, August 26, 1922. Favorably reported in the House by the Committee on Interstate and Foreign Commerce, August 29, 1922.

Since a shortage of coal this winter may develop into a serious health problem, we are including a résumé of the coal bill before Congress.

This legislation places the Federal control of coal prices and distribution of coal in the hands of a Federal Fuel Distributor, to be chosen by the President. The legislation sets out the fact that "A National emergency exists which endangers the public health and general welfare of the people of the United States."

It empowers the Federal Fuel Distributor to ascertain:

1. The available supply of coal and other fuel and the extent of threatened shortage;
2. The fields of production and best methods of distribution;
3. The prices normally and usually charged for such coal and whether current prices are just and reasonable;
4. The kind and location of consumers.

The Fuel Distributor is required to issue orders for priorities in car service, embargoes and other suitable measures in favor of or against any carrier or region, and to take other

steps necessary for priority in car service and distribution of coal.

The bill fixes a fine and prison penalty for any fraud practiced by a person or corporation violating any order made by the Fuel Distributor.

A similar bill, S. 3940, was reported in the Senate, August 29, 1922.

Changes in Personnel of the U. S. Public Health Service. In accordance with regulations of the U. S. Public Health Service and the policy of replacing administrative heads every four years, the following six assistant surgeon generals have been appointed in place of the present incumbents:

Division of Venereal Diseases: Dr. Mark J. White to succeed Dr. C. C. Pierce.

Division of Marine Hospitals and Relief: Dr. F. C. Smith to succeed Dr. C. H. Lavinder.

Division of Scientific Research: Dr. A. M. Stimson to succeed Dr. J. W. Schereschewsky.

Division of Foreign and Insular Quarantine: Dr. J. D. Long to succeed Dr. R. H. Creel.

Division of Domestic Quarantine: Dr. W. F. Draper to succeed Dr. A. J. McLaughlin.

Division of Sanitary Reports and Statistics: Dr. B. J. Lloyd to succeed Dr. B. S. Warren.

One million dollars Government Reward for Discovery of Disease Cures, H. R. 12409. Introduced by Representative Sprout, August 23, 1922. Referred to the Committee on Interstate and Foreign Commerce.

The sum of \$1,000,000 in ten equal annual installments is appropriated, by this measure, to any individual discovering a successful cure for tuberculosis, cancer, pneumonia, paralysis, epilepsy, or dementia praecox. A board would be established, consisting of the Surgeon General of the Army, the Surgeon General of the Navy, and the Surgeon General of the U. S. Public Health Service, to investigate any discoveries submitted and to authorize payments of the awards. This board is also empowered to recruit an advisory board, composed of eminent specialists, to facilitate its investigations. It is provided that when payment has been made for a discovery, no further payment shall be made for discovery of a treatment for the same disease.

INSTRUCTIVE DISTRICT NURSING ASSOCIATION.

MONTHLY HEALTH BULLETIN.

July and August showed a slight increase in work over that of the same period last year, with a total of 4,526 new patients being admitted and 49,000 visits made, but the work was light, as is customary with mid-summer months.

HEALTH CONDITIONS PECULIAR.

Certain peculiarities marked the health conditions during this period. Normally, the bulk of the work shifts almost as regularly as the

seasons, from digestive diseases in summer, to respiratory in winter. But during July and August the expected increase in digestive diseases did not occur; and while respiratory diseases dropped to the usual low summer rate during July, they increased again in August, particularly bronchitis and pneumonia.

ACUTE AND COMMUNICABLE DISEASES.

Typhoid fever showed a most encouraging decrease. Four new cases were admitted in August, against 12 in August, 1921; in July, none, against 6 cases in July of last year. Measles, which have been very prevalent, dropped to 94 new cases in July, the lowest number in several months, and to 35 in August, the latter figure still, despite the sharp decline, heavier than that of August, 1921. Whooping cough increased in August.

INCREASE IN ACCIDENTS.

In July there were fewer cases of burns, traumatism, fractures, etc.,—74 as compared with 79,—while in August there was an increase,—103 as compared with 59 of August, 1921.

CHRONIC DISEASES.

Cancer and diseases of the heart, which have been steadily increasing for several months, showed a big drop in July, when there were only 16 new cases of cancer and 19 of diseases of the heart admitted.

In August the decrease in heart cases continued, but cancer again increased.

NUTRITION CLASSES.

The nutrition classes, which have been established in the Hyde Park Health Centre for the benefit of those children found by the physician in charge of the Child Health Clinic to be 7% or more underweight, were continued during July and August, 9 classes being held, with a total attendance of 81. A majority of these children were more than 10% underweight.

The classes have aroused a surprising interest and cooperation in both parents and children, and while the physical results have been highly satisfactory, the education resulting from the group instruction has been unexpectedly successful.

VITAL STATISTICS.

In looking over the report issued under the direction of Mr. Edgar A. Bowers, State Registrar of Vital Statistics, it occurred to the Editor that since some faulty interpretations relating to maternal deaths might exist in the mind of a casual reader, further explanation would be of assistance, and a letter was written asking for interpretation of the figures.

The report as a whole is of great value, both because of the substance, and also because of its unusually early completion and distribution. The Registrar is entitled to great credit. For one can find almost everything relating to vital statistics in the volume. The explanatory chapters aid materially in the interpretation of the figures. The reply of the Registrar is appended.

Editor, Boston Medical and Surgical Journal:

In reply to your letter of September 11 relative to an apparent discrepancy in the tables on page 76 and page 90 of the 1921 report:

I would point out that on page 76 the total number of deaths in the puerperal state is given as 580. The first item, No. 143, you will note, includes its sub-divisions A, B, and C. Also sub-divisions 145, A, B, and C, are included in 145. This occurs wherever there is an indentation in the type, and is in accordance with the international classification. However, I can easily see where one would get mixed up, and on the next printing intend to take some steps either by larger type or by a note to show that these sub-divisions are included in the items of which they are a part. On page 90 the abridged list follows the abridged list furnished by the Census Bureau, although the new abridged list has not been received, and this abridged list is made up in conformity with the old one as near as may be. You will note that items 31 and 32 in the abridged list make the total of 580 referred to on page 76.

I trust the above will explain the question asked in your letter. If there is anything further I can help you on, I will be very glad to do so.

Very truly yours,

EDGAR A. BOWERS,

State Registrar of Vital Statistics, Office of the Secretary of the Commonwealth of Massachusetts.

RÉSUMÉ OF COMMUNICABLE DISEASES

AUGUST, 1922.

GENERAL PREVALENCE.

There were 3,304 cases of communicable diseases reported during the month: for July, 1922, there were 4,093; for August, 1921, 3,295 cases. For the past month there has been a marked decrease in chicken-pox, measles and scarlet fever. Diseases showing an increase are as follows: typhoid, poliomyelitis, diphtheria, whooping cough, meningitis, tetanus, septic sore throat, tuberculosis (pulmonary).

Anterior Poliomyelitis.—Fifty-five cases were reported for the month. These cases were widely distributed over the eastern part of the State, but there was no sharply localized outbreak. The number of cases for July, 1922, was 23; for August, 1921, 61 cases.

Diphtheria.—Four hundred eight-two cases were reported for the month, a considerable increase over 380 for July; for August, 1921, there were 516 cases.

Dog-bite requiring anti-rabic treatment was reported in 23 cases for the month, as against 36 for July, 1922. The number of cases reported for August, 1921, was 18.

Hookworm.—There were 31 cases reported for the month, but practically all were among aliens who are being held for deportation.

Measles was reported in 338 cases, a very marked decrease for July, 1922, when 1,275 cases were reported; August, 1921, showed 268.

Ophthalmia neonatorum was reported in 100 cases for the month, against 63 for July, 1922, and 141 for August, 1921.

Tuberculosis, pulmonary, was reported in 547 cases for the month: the number for July, 1922, was 506, and for August, 1921, 515.

Typhoid Fever.—One hundred and one cases were reported for the month, 73 for July, 1922, 113 for August, 1921.

Whooping Cough.—Four hundred eighty-three cases were reported during the month, 413 for July, 1922, 375 for August, 1921.

RARE DISEASES.

Anterior poliomyelitis was reported from Ashland, 1; Attleboro, 3; Boston, 10; Brookline, 2; Dartmouth, 1; Dudley, 1; Everett, 2; Fall River, 7; Lawrence, 1; Lynn, 2; Marblehead, 3; Medford, 1; Melrose, 1; Nantucket, 1; New Bedford, 1; Newton, 1; Northbridge, 1; Somerville, 7; Springfield, 1; Swampscott, 2; Taunton, 1; Webster, 3; Yarmouth, 1; Methuen, 1; total, 55.

Dog-bite requiring anti-rabic treatment was reported from Arlington, 1; Attleboro, 1; Belmont, 1; Billerica, 1; Boston, 3; Cambridge, 3; Lowell, 7; Lynn, 1; Methuen, 1; Somerville, 1; South Hadley, 3; total, 23.

Dysentery was reported from Adams, 1; Boston, 2; Chelsea, 2; Melrose, 1; total, 6.

Encephalitis lethargica was reported from Lynn, 1; Salem, 1; Webster, 1; total, 3.

Epidemic cerebrospinal meningitis was reported from Boston, 2; Fall River, 2; Lowell, 1; Southbridge, 1; total, 6.

Hookworm was reported from Boston, 31.

Malaria was reported from Boston, 1; Lowell, 1; total, 2.

Pellagra was reported from Boston, 1.

Septic sore throat was reported from Boston, 1; Fall River, 1; Haverhill, 1; New Bedford, 2; Salem, 3; Whitman, 1; Winchester, 1; total, 10.

Tetanus was reported from Beverly, 1; East Bridgewater, 1; Gloucester, 1; Haverhill, 1; Hingham, 1; Melrose, 1; Northampton, 1; Worcester, 1; total, 8.

Trachoma was reported from Boston, 4.

DAMAGES ALLOWED PHYSICIAN FOR PERSONAL INJURY.

The Supreme Court of Pennsylvania says that the plaintiff, a practising physician, aged 69, while a passenger in a car, was struck on the head by a suitcase or hand satchel falling from a rack above the seat in which he was sitting. There was evidence that he was rendered unconscious, and, as a result of the injury, became unable to practise his profession to the same extent as before the accident, his earnings having decreased from \$7 or \$10 a day to \$2.50 a day; that his eyesight and memory had become impaired, as had also his general physical condition. A verdict was rendered in his favor for \$7,250. The court below, having refused a new trial, the defendant appealed. The statement of the question involved was whether the size of the verdict was manifestly too great and plainly the result of prejudice. The Supreme Court found nothing in the record indicating prejudice against the defendant, and it cannot say that the verdict was so excessive as to warrant its interference on that ground, in view of the testimony establishing the injury received by the plaintiff and its effect on him and the resultant decrease in the receipts from his professional calling; wherefore, the judgment for the plaintiff is affirmed.—*Journal of the Medical Society of New Jersey.*

LIVES SAVED BY THE USE OF LABORATORY ANIMALS.

THE Colorado Association for the Protection of Public Health is planning for the publication of reports of cases which illustrate the value of vaccines and sera derived from laboratory animals, or of any use of animals in the saving of human life.

This information will be of value in combating the opponents of the use of animals in the treatment and prevention of disease.

If physicians would report all such material in concise form for use as occasion requires, good would result.

THE IODINE SUPPLY.

J. F. McCLENDON, in an article in *Science* gives the results of his analysis of sea water. According to his investigations, about all of the earth's iodine is found in sea water, and amounts to sixty billion metric tons.

In order to overcome the prevalence of goiter he recommends the use of a table salt prepared from sea water. By the method recommended by him, the expense would be no greater than now exists. At the present time iodine is not found in table salt.

The addition of powdered kelp to food is recommended by Dr. Turrentine. Small amounts of kelp are not recognized, and the iodine content is valuable. Although sea foods may supply some iodine, the amount is too small to be of much value.

It is becoming quite generally believed that the goiter belt is included to a large extent in mountainous and glaciated regions.

AMERICAN RELIEF ADMINISTRATION.

Saratov, Russia, August 25—Nearly half a million persons have been inoculated in this district, as a result of the inoculation campaign against disease being conducted throughout Russia by the American Relief Administration. Dr. John E. Toole, A. R. A. medical supervisor for this district, has submitted to Moscow figures showing that 498,128 have been inoculated with anti-cholera serum and 251,156 have been vaccinated for the prevention of smallpox.

In the smallpox vaccination almost 90 per cent. were "takes," which is regarded as a high percentage. The vaccine and other medical supplies were made possible by the American Red Cross appropriation to the A. R. A., and of surplus medical supplies furnished by the United States army.

Obituary.

JOHN RICHARD SLATTERY, M.D.

DR. JOHN R. SLATTERY, Superintendent of St. Elizabeth's Hospital, Brighton, and private physician to his Eminence, Cardinal O'Connell, on his recent journey to Rome, dropped dead on the golf links of the Woodlawn Club at Auburn-dale, September 11, 1922, after a round with his brother, the Rev. Laurence W. Slattery, rector of the Church of Our Lady Help of Christians, Newtonville.

Dr. Slattery was born in South Boston, January 1, 1867, was educated in the public schools of the district, at Boston Latin School, Georgetown University, Washington, D. C., and at Harvard Medical School in the class of 1891. He

settled in practice in South Boston. On the taking over of St. Elizabeth's Hospital by the Catholic Archdiocese of Boston in 1911, Dr. Slattery was appointed superintendent, headed the drive for the funds with which the five new buildings on Cambridge street, Brighton, were erected, and has been the head of the institution since.

He was created a knight of the Order of the Holy Sepulchre by Pope Pius X. and was also a member of the Third Order of St. Francis. Among the societies in which he held membership were the American Medical Association and the Massachusetts Medical Society.

Correspondence.

ANOTHER LETTER FROM MR. NUNN.

Boston, Mass., September 1, 1922.

Mr. Editor:

May I write again to say how greatly I appreciate your courtesy and fairness in publishing my letter in answer to your editorial of Aug. 17, dealing with my radio talk on vaccination?

I wish it might be possible always to discuss the subject of vaccination with gentlemen of the medical profession, without heat or acidity on either side.

It seems quite possible to me that our friends of the medical fraternity do not realize how instinctively the average man or woman revolts at the thought of vaccination, when the matter employed in the practice is described in simple terms. In spite of the ordinary man's confidence in physicians, and his high regard for their calling, he does not readily credit the possibility of safeguarding the health of an already healthy child by infecting his blood with putrid matter taken from a diseased animal, especially if he be told that the original source of this particular strain of virus was matter taken from the pustules on the body of a human smallpox victim.

The ordinary citizen is quite certainly becoming doubtful as to the beneficial intent of ultra-scientific investigations involving human beings. Such a proposal as that contained in your editorial of August 31, to the effect that the value of vaccination be determined by subjecting two hundred children to contact with smallpox, advanced by you with apparent seriousness, is not calculated to dispel the growing sense of uneasiness, felt by many sane people, regarding the seeming trend of the so-called advanced section of the medical profession, toward human experimentation.

I appreciate that your suggestion was doubtless ironical, for it is unthinkable that you would either countenance or participate in so hideous an experiment upon children, vaccinated or unvaccinated. Yet, a suspicion is more widely entertained by the common run of people than you may be aware of, that those engaged in medical research are none too respectful of the fundamental human rights of inmates of orphanages, hospitals, and asylums, to exemption from being treated as material for clinical experimentation.

Were vaccination now, for the first time, proposed to the medical profession, I fully believe that it would be rejected, with scorn. The standard arguments for this practice, if now freshly advanced, would appeal to minds uncontaminated by a century of propaganda as the *reductio ad absurdum* of material

ism; a veritable "counsel of despair": a vain hope of finding health and life in the very essence of disintegration and death.

Sincerely yours,

HENRY D. NUNN,
Manager and General Counsel, Medical Liberty
League, Inc.

COMMENT BY DR. CROFT.

September 7, 1922.

Mr. Editor:

I thank you for your editorial reply to the letter of the General Counsel of the Medical Liberty League on "Smallpox Treatment and the Facts Relating to Vaccination." Your courteous attitude, forceful arguments and apt similes should commend themselves to every thoughtful physician.

Your explanation of the apparent ignorance of the former president of a State Society is unquestionably true, and typical of hundreds of us whose special work does not require accurate, detailed and up-to-date information on the methods of preparing the different things which we use for therapeutic ends, but we are and should be "thoroughly dogmatic" as to the efficacy of the underlying principles when based on extended experiences and which have not yet been successfully controverted.

You do well to emphasize the solemn obligation which we physicians have assumed to protect against disease those who through ignorance or otherwise, cannot help themselves, and that the proper discharge of such obligation may even require entering upon an unpleasant and personally disagreeable controversy in order that authoritative facts shall not be undermined by sophistry and specious arguments.

The false interpretations being placed on unguarded remarks of physicians, by the supporters of the various cults, emphasize anew the obligations which physicians are under to inform themselves of proven facts, to defend them on occasion, and to change their attitude only as a result of scientific proof. Too many of us today are aiding false doctrine by our supine attitude of indifference or cowardice.

Yours truly,

B. P. CROFT.

THE HARRISON NARCOTIC ACT.

September 8, 1922.

Mr. Editor:

In your editorial discussion of the Harrison Narcotic Act, in the issue of August 31, page 341, you say:

"The registration of physicians with the right conferred to use narcotic drugs is logical, but revenue tax is abhorrent and should be repealed."

The tax is the sole foundation upon which the Harrison Narcotic Law rests. Repeal the provisions of the act that impose the tax and the entire jurisdiction of the United States Government over the manufacture, sale and distribution of narcotic drugs within the boundaries of the State falls, except as the Federal Government might regulate the distribution of such drugs through the mail.

It can hardly be denied that the United States Government in enacting the Harrison Narcotic Law utilized its constitutional taxing power in a way that was never conceived by the framers of the Constitution, to take over certain police duties normally belonging to the State. Its motive, however, was such a worthy one and the trespass has been tolerated so long and has been so broadly sustained by the United States Supreme Court that there is no likelihood that the United States Government will retire from the field.

The most that can be hoped for is that the tax will be reduced to the nominal amount originally fixed, \$1.00, or possibly less, and that the regulations governing the medical profession in prescribing and administering narcotic drugs may be kept within the limits of the Act and within reason. A request for a reduction of the tax was submitted to the United States Treasury Department by the Committee on Narcotic Drugs, Council on Health and Public Instruction, under date of May 6, 1921, and the matter is still pending.

Yours very truly,

Wm. C. Woodward,
Executive Secretary.

NOTE: Our esteemed correspondent agrees with the spirit but objects to the text of the editorial in question. A registration fee sufficient to pay the cost of operation of the system is logical and would not be construed as a tax. When the amount provides for revenue it is then that objection can properly be made.

Dr. Woodward, in the last part of his communication, submits evidence of his belief that the "tax" is too large. Most physicians are not seriously affected by the three dollars charged. It is the spirit of the Government, in its evident purpose to impose an unnecessary tax on members of a profession who have contributed more in unpaid service to the people than any other class of citizens, that makes the tax abhorrent. Physicians who are not criminals should not be compelled to contribute money for the suppression of crime even though the criminal makes unlawful use of drugs which the doctor employs legally.

Would it not be as logical to tax doctors for the maintenance of that part of police departments that is employed in investigating and prosecuting abortionists?

—EDITOR.

EXPERTO CREDE.

Mr. Editor:

In the BOSTON MEDICAL AND SURGICAL JOURNAL in the review of my booklet, "The Treatment of Ordinary Diseases," exception is taken to my views about acute middle-ear disease, acute appendicitis and digitalis. My judgment in these affections and in the use of digitalis has all been supported time and again already, by statements based upon a wide experience. It is unfortunate for those practitioners of a late date, that in their practice and convictions, they are supported almost solely by what they hear and read in medicine, which unfortunately does not take count sufficiently, if at all, of what has been acquired by lifelong observation, both in hospital and private practice. Further, it would be well, not infrequently, if the physicians who write reviews of books, would first acquaint themselves with previous works of the writer whom they criticize.

BEVERLY ROBINSON.

NOTICES.

BRISTOL NORTH DISTRICT MEDICAL SOCIETY. Fall Meeting, Taunton Woman's Club, Thursday evening, September 21, 1922. 6.30 Supper. 7.30 Business Meeting. 8.00 Dr. Frank H. Dunbar of the Department of Pathology and Bacteriology of the Tufts College Medical School will speak on "The Physician and the Laboratory."

Arthur R. Crandell, M.D.

Secretary.

NOTICE TO SECRETARIES.

Secretaries of societies are requested to forward notices of coming meetings for publication. Reporters will please forward early reports of meetings that have been held with a concise account of the salient features.

UNITED STATES CIVIL SERVICE EXAMINATION.

RESEARCH ASSISTANT IN CHILD HYGIENE.

Receipt of Applications to Close October 10, 1922.

The United States Civil Service Commission announces an open competitive examination for research assistant in child hygiene. Vacancies in the Children's Bureau, Department of Labor, at \$1600 to \$2000 a year, and in positions requiring similar qualifications, at these or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion. For particulars apply to United States Civil Service, Washington, D. C.

SOCIETY MEETINGS.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue. The incomplete details and omission of names of many societies is because the information has not been furnished, although the JOURNAL has requested information for publication. Free publication of dates of meetings may accommodate many numbers of societies. Several physicians have spoken of the importance of having a schedule of meetings published so that arrangements may be made for special meetings on dates which may not conflict.

It may be possible to adopt the custom of the publication of notices of stated meetings in the JOURNAL and if this is generally understood, secretaries of societies could save time and expense. If general cooperation can be secured this plan can be made permanent.

DISTRICT SOCIETIES.

Barnstable District—Hyannis,—November 3, 1922, February 2, 1923, (Annual Meeting)—May 4, 1923.

Bristol North District—Place undecided—September 21, 1922.

Bristol North, Bristol South, Barnstable and Plymouth Districts will hold joint meetings sometime this fall.

Bristol South District—Fall River,—November 2, 1922, May 3, 1923.

Essex North District—Haverhill, (Semi-Annual Meeting)—Jan. 3, 1923. Y. M. C. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Essex North, Essex South, Middlesex North and Middlesex South Districts will hold joint meetings October 18. Place undecided.

Hampden Districts—With Hampshire District in Holyoke. Early part of September. Regular meeting in October.

Hampshire District—With Hampden District in Holyoke. Early part of September.

Middlesex North District—Meetings Wednesday, October 25, 1922; Wednesday, January 31, 1923.

The four western districts plan to hold a joint meeting early in October.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

New England Surgical Society. 5th Annual meeting will be held at Burlington, Vermont, on September 22 and 23, 1922; P. E. Truesdale, Fall River, Mass., Secretary.

NEW ENGLAND TUBERCULOSIS CONFERENCE, Augusta, Maine,—September 25, 29 and 30. Sessions will be held at the State House. Headquarters at the Augusta House.

September 25. Speakers: Dr. Arthur L. Wallace, Dr. Stephen J. Mosher, R. V. Spencer, Miss Elena M. Crouch, Dr. Charles Duncan.

September 29. Speakers: Dr. E. O. Otis, Dr. R. B. Kerr, Dr. J. Pinkney, Basil G. Eaves, Dr. E. R. Kenley, Dr. E. D. Merrill.

September 30. Speaker: Dr. J. C. Cobb.

At noon a modern health crusade luncheon will be held at the Augusta Hotel. Speaker will be Harold W. Sloucum.

October, 1922. Boston Tuberculosis Association. Tuberculosis Institute for Physicians will be held on October 5 and 6 at the Massachusetts General Hospital, Bernice W. Billings, Boston, Executive Secretary. October, 1922. The New England Society of Psychiatry will hold its next meeting on October 5th, at the Connecticut State Hospital, Middletown, Connecticut. Readers: Dr. Walter Tipton and Dr. Frankwood E. Williams, New York City. New England Dermatological Society, Wednesday, October 11, 1922, at 3.30 p. m., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary. Clinical Congress of the American College of Surgeons will be held in Boston, Mass., on October 23-27, 1922, Franklin H. Martin, Chicago, Director-General, Massachusetts Association of Boards of Health, October 26, 1922, Boston, Mass., W. H. Allen, Mansfield, Mass., Secretary. New York and New England Association Railway Surgeons 32nd Annual Meeting at New York City, October 25, 1922, Donald Guthrie, Sayre, Pa., Secretary.

November, 1922. Massachusetts Society of Examining Physicians, (Date and place of meeting undecided), Hilbert F. Day, Secretary. National Cancer Week, November 19-25, 1922.

December, 1922. New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3.30 p. m., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

January, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston, W. H. Allen, Mansfield, Mass., Secretary.

February, 1923. New England Dermatological Society Meeting, February 14, 1923, at 3.30 p. m., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

March, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary.

April, 1923. New England Dermatological Society Meeting, April 11, 1923, at 3.30 p. m., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston, W. H. Allen, Mansfield, Mass., Secretary.

May, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided) American Pediatric Society Meeting, May 31, June 1, and 2, 1923, at French Lick Springs Hotel, French Lick, Ind., H. C. Carpenter, Secretary.

June, 1923. American Medical Association, San Francisco, June 25-29, 1923, Alexander R. Craig, * Chicago, Ill., Secretary.

July, 1923. Massachusetts Association of Boards of Health, July 26, Nantuaet, W. H. Allen, Mansfield, Mass., Secretary.

*Deceased Sept. 2, 1922.

PAPERS AND DISCUSSIONS OF THE SECTION OF TUBERCULOSIS.

AT ITS MEETING AT THE HARVARD MEDICAL SCHOOL, BOSTON, JUNE 13, 1922.

TUBERCULOSIS IN CHILDREN FROM THE STANDPOINT OF THE PEDIATRIST.

BY JOHN LOVETT MORSE, A.M., M.D., BOSTON.

It would be impossible for me, of course, to cover the whole subject of tuberculosis in childhood in the 15 or 20 minutes allotted to me. I feel quite confident, moreover, that no one wishes me to do this, even if I were competent to do it. What is wanted of me, I think, is a summary of some of my own impressions and experiences with this disease in childhood during my career as a pediatrician.

ETIOLOGY.

Tuberculosis in childhood may be caused by either the human or the bovine type of organism. It seems to me that the relative frequency of infection with these two types is of no practical importance. Both may cause the disease. We must, therefore, guard against both. Infection with the bovine bacillus may be prevented by the elimination of tuberculous cows with the aid of the tuberculin test and by the general

pasteurization or boiling of milk. Infection with the human type of organism can be prevented by the separation of infants and young children from adults with open tuberculosis and diminished by instruction in and enforcement of the proper precautions to be taken to prevent contagion.

MODE OF INFECTION.

The relative frequency of infection through the respiratory and digestive tracts seems to me likewise to be of little practical importance. Infection may take place through either path. Hence, we must guard both. It is also of no practical importance, if infection takes place through the respiratory tract, whether there is a primary focus in the lung, as Gohn teaches, or the bacilli pass directly through the lung to the tracheobronchial glands, as was until recently believed. The result is the same either way. Furthermore, what difference does it make, practically, when tubercle bacilli get into the tracheobronchial lymph nodes, whether they come directly through the bronchi and lungs or indirectly through the stomach and intestines?

TUBERCULIN TEST.

Although years ago I used the subcutaneous and eye tests, the only one with which I am now familiar is the skin, or Pirquet, test, and the conclusions which I shall draw are based on this test alone. This test is of great value in infants. A positive test in a sick baby, showing

no other evident cause for its illness, is very strong evidence in favor of the trouble being tuberculosis. A negative test, in my experience, almost positively excludes tuberculosis as the cause of the illness, unless the baby is manifestly overwhelmed by the infection. I am aware that in certain instances a positive test may be obtained after repeated trials. I am somewhat doubtful as to the value of a positive test under these circumstances, although my experience has hardly been sufficient, perhaps, to justify a definite opinion.

The test is of less value in children, and the older the child, the less is the value of the test because of the steadily increasing frequency of infection with age. A negative test is of great importance in childhood, however, and practically rules out tuberculosis unless the child is evidently overwhelmed by some infection. Because of the severity of the infection, the test is usually negative in acute miliary tuberculosis and in tuberculous meningitis, which is, of course, a variety of acute miliary tuberculosis. I have also seen it absent several times in tuberculous peritonitis, even when it was not of the miliary, aseptic type. A positive test is of much less value than a negative in childhood, because, while it shows that the child has been infected with tuberculosis, it does not show that the illness which it has is tuberculous. It may as well be due to some old or latent infection, or to the infection of some hidden gland, as to the illness from which the child is suffering. It is of some help, however, if the lesions which the child has may well be tuberculous and there is no other evident cause for the illness. Great care must be taken about calling pulmonary lesions tuberculous, however, simply because the tuberculin test is positive. I have seen many mistakes of this sort made, because physicians did not realize that physical signs merely indicate certain changes in the lung tissue and show nothing as to the cause of these changes.

TUBERCULIDS.

The presence of tuberculids, which are small, dark red papules, which often have a scaly apex, shows evidence of an active and usually of a generalized infection with tuberculosis. Their presence is of especial value, because they are most often found in just the cases in which the tuberculin test is negative, that is, in cases of acute miliary tuberculosis. They should be looked for, therefore, in all cases when this disease is a possibility. Their presence usually, but not always, indicates a fatal termination.

TUBERCULOUS INFECTION.

It is well known that new-born babies almost never show a positive tuberculin test. The test is almost always negative in young infants, but the proportion of positive reactions increases steadily through infancy and childhood, while

all adults give a positive reaction; that is, a steadily increasing proportion of infants and children become infected with tuberculosis. The important thing, therefore, is not so much whether they are or have been infected with tuberculosis, but whether the infection is or is not active. In this connection it has always seemed foolish to me to speak of a pretubercular stage. I have, in fact, never been quite certain what those who use this term mean by it, whether they mean a condition of malnutrition or increased susceptibility from some cause or other before tubercle bacilli enter the body or a period after tubercle bacilli have entered the body, but in which there is no active process giving symptoms. In either case it seems to me that the term is a poor one. A child either has or has not been infected with tuberculosis; therefore, he either is or is not tuberculous. If the infection is latent, he has no symptoms. If it is active, he has symptoms. We should, therefore, it seems to me, think whether a child has or has not been infected with tuberculosis, and, if he has, whether the infection is active or inactive.

The tendency of the majority of physicians is to consider that every child who is delicate or poorly nourished or has a continued fever is tuberculous. My experience is that tuberculosis is seldom the cause, when children are delicate or poorly nourished. A careful study of their parentage and of their diet and mode of life will almost always reveal the cause of the delicacy or malnutrition. In my experience, also, the least probable cause of a continued temperature in infancy and childhood is tuberculosis. Careful investigation will almost always show some error in diet, some disturbance of the digestive tract, some disease of the nasopharynx and accessory sinuses or pyelitis to account for the fever. Furthermore, many apparently well children that have a negative tuberculin test and in whom no evidences of disease can be found, have a temperature somewhat higher than what is ordinarily considered normal in the afternoon, especially if they have been excited or playing hard. In my experience, also, tuberculosis is a rare disease in infancy and childhood, both in private and hospital practice. I seldom see tuberculosis at this age in my office or consultation practice, except tuberculous meningitis and tuberculous peritonitis. In 1921, according to the report of the Children's Hospital, Boston, the diagnosis of tuberculosis in any form was made less than 100 times in something over 10,000 diagnoses in the Medical Out-Patient Department, unless 104 cases of cervical adenitis are all considered to be tuberculous. In the wards the diagnosis of tuberculosis in all forms was made only 36 times out of 822 diagnoses. These figures seem to demonstrate the relative infrequency of active tuberculosis in childhood.

TUBERCULOSIS IN INFANCY.

A tuberculous infection in infancy may be local, never cause any symptoms and never be recognized. Contrary to the general belief of a few years ago, a positive tuberculin test does not by any means condemn a baby to death. It is certain that many babies become infected with tuberculosis that never show any evidences of this infection, except a positive tuberculin test, or, at any rate, do not show any evidences of it until later in childhood or in adult life, when the infection may become active. Nevertheless, the tendency for tuberculosis to become generalized is much greater in infancy than it is later. When it becomes generalized, it may take either one of two forms, the acute miliary or what used to be called chronic diffuse tuberculosis. This term, which seems to me to be a good one, appears to have fallen into disuse during recent years. It describes better than any other term, I think, a condition which is common in infancy, but uncommon in childhood and adult life. In this condition there are tuberculous lesions in many or all of the organs, but the number is very much less than is the case in acute miliary tuberculosis. The baby consequently lives longer and the individual lesions have time to become larger than in acute miliary tuberculosis, although they may not give any more definite physical signs. The duration of chronic diffuse tuberculosis is, therefore, one of months rather than of weeks, as it is in acute miliary tuberculosis. A tuberculous infection in infancy, especially when it is of the chronic diffuse type, may give only the evidences of malnutrition with no localizing physical signs. It is wise, therefore, when a baby, that is reasonably well fed, and does not show any marked evidences of indigestion, does not gain properly, and shows other evidences of malnutrition, to suspect tuberculosis as the cause of its failure to thrive. Tuberculous bronchopneumonia is a very common form of tuberculosis in infancy. There is, as a rule, nothing about the onset to suggest that the trouble in the lung is tuberculous. Whenever the bronchopneumonic process continues localized for a long time in one spot, new spots continue to develop without the clearing up of the old, or the disease is of unusually long duration, tuberculosis should always be suspected. The physical signs do not differ, however, in any way from the physical signs of bronchopneumonia due to other organisms. Tuberculous meningitis is also more common in infancy than in childhood, because of this tendency to generalization at this age. While tuberculosis in infancy which gives definite physical signs carries a very grave prognosis, it is not, as we used to think, invariably fatal. Babies with recognizable tuberculosis not infrequently recover.

LOCAL TUBERCULOSIS.

Cervical Adenitis. It is often very difficult to determine whether enlarged glands in the neck are tuberculous or not. In general it is true that glands which develop rapidly after an acute infection of the throat are not tuberculous, while glands which come up slowly without any acute infection in the throat usually are tuberculous. There are, however, many exceptions to this rule. For some reason or other tuberculosis of the cervical lymph nodes does not tend to spread from them to other parts of the body. It almost always remains a localized infection. It would be presumptuous for me to say much about the treatment of tuberculous glands in the neck. It has seemed to me, however, that when they are enlarged it is wise, unless they are broken down, to first take out the tonsils and later to remove the glands. It is unwise, in my experience, to hope that tuberculous cervical glands will disappear of themselves.

Tracheobronchial Adenitis. The tracheobronchial lymph nodes are probably more often involved in tuberculosis in childhood than any other portion of the body. This involvement is shown by extension of the bronchial voice, whisper and respiration below the seventh cervical spine. D'Espine's sign, that is, a whispering sound heard after the spoken voice over the spinous processes of the vertebra, dullness on percussion below the seventh cervical spine and interscapular dullness. The enlargement is always considerable when there is interscapular dullness. It must never be forgotten, however, that these glands may be enlarged from other causes than tuberculosis. The finding of evidences of their enlargement does not, therefore, in itself justify the diagnosis of tuberculosis.

Pulmonary Tuberculosis. Tuberculosis of the lungs in early life almost always starts at the roots of the lungs and extends outward and downward. It very seldom begins at the apices. In infants and young children the distribution is very likely to be bronchopneumonic in type. It must not be taken for granted that every prolonged process in the lungs in infancy and childhood is tuberculous. As a matter of fact, such prolonged processes are more likely not to be than to be tuberculous. They are very frequently influenzal in origin. Such processes may persist for weeks or even months, and then clear up entirely. In my experience, cavities in the lungs in childhood are very seldom due to tuberculosis, because children, as a rule, die before cavities have formed. Cavities are usually due to a previous abscess of the lung, or more often to bronchiectases resulting from fibrous changes in the lungs due to a previous pneumonia which, instead of resolving, has organized. They are also sometimes due to chronic bronchitis or are the result of some congenital anomaly.

Abdominal Tuberculosis. There are three main types of tubercular peritonitis; the ascitic type, in which the peritoneum is studded with

miliary tuberculosis and filled with fluid; the caseous type, in which there are large masses of newly formed tuberculous tissue in the mesentery and omentum, with sometimes a small amount of fluid; and the adhesive type, in which the intestines are all bound together, and in which there is no fluid. The physical signs must evidently be very different in these three types. The prognosis is far better in tubercular peritonitis than was formerly supposed. Many cases recover. It is impossible, however, to tell in the beginning whether an individual patient will do well or not. Personally, I am opposed to operation, except in the ascitic form, when it has failed to yield to medical treatment and repeated tapping, and in the other forms, when there is obstruction. In my opinion the prognosis is as good, or better, under medical treatment than with operation. Incidentally, in doubtful cases, the demonstration of disease in the testicle is very strong evidence in favor of tuberculosis of the peritoneum.

There seems to be a good deal of misunderstanding as to the use of fat in the food in these cases. It used to be given routinely in order to improve the nutrition, but then we were told that, on account of the involvement of the mesenteric lymph nodes, fat could not be absorbed and consequently did harm. The truth of the matter is that in some cases the mesenteric glands are involved and fat cannot be absorbed, while in others they are not involved and fat can be absorbed. The only way to determine whether they are involved or not, is by an examination of the stools. If the stools show that fat is not absorbed, the fat should be cut out of the diet. If they show that fat is absorbed, fat should be given and pushed.

Tuberculosis of the mesenteric and retroperitoneal glands is not uncommon. It may give rise to acute symptoms, suggesting those of appendicitis or acute intestinal obstruction. This possibility should never be forgotten in the differential diagnosis of acute abdominal conditions in childhood.

Meningeal Tuberculosis. I know of no condition in which it is harder to make an early diagnosis than tuberculous meningitis. There is nothing characteristic about the early symptoms. Vomiting without evident cause, headache, and disinclination to play are perhaps among the earliest symptoms, but these symptoms are common to many other conditions. The only way in which a physician can always make an early diagnosis is to speak of it as a possibility whenever a child is sick and there is no very evident cause for the illness. I fear, however, that if a physician did this he would soon lose all his patients. It must not be forgotten that the flaccid type of tuberculous meningitis is almost, if not quite, as common as the type with spasm, rigidity of the neck and convulsions, especially in infancy. I have seen many cases of tuberculous meningitis

go through their whole course completely flaccid and with diminished or absent reflexes, and, in babies, even without bulging of the fontanelle. It is true that a very few patients have apparently recovered from tuberculous meningitis. The number of cases is so small, however, that we are not justified, it seems to me, in holding out any hope whatever of recovery in tuberculous meningitis. We must remember, however, that other conditions, such as syphilitic meningitis and encephalitis, may strongly resemble tuberculous meningitis in their symptomatology and that the findings in the cerebrospinal fluid in these conditions are the same, except for the absence of tubercle bacilli. There is always a chance for error, therefore, unless tubercle bacilli have been found in the spinal fluid.

I am confident that lumbar puncture has no curative action in these cases. In the spastic cases and in the cases with marked symptoms of cerebral irritation, lumbar puncture relieves them more, however, than any other method of treatment.

SURGICAL TUBERCULOSIS.

The physician must always bear in mind the possibility of surgical tuberculosis. He must remember that backache and pains in the legs may be due to tuberculosis of the spine. He must not forget that pains in the extremities are not always due to rheumatism, but may be due to tuberculosis of the joints. In fact, he should make the examination of the spine and extremities a part of his routine physical examination, in order that he may never miss conditions of this sort.

TREATMENT.

In my opinion the preventive treatment of tuberculosis is by far the most important. When tuberculosis has developed, the treatment consists of rest, food, fresh air, both day and night, and all the sunlight that there is. I have had but little experience with the Rollier treatment, but from what I have seen of it, I am convinced that it is very useful in tuberculosis of the bones and of the peritoneum. I have no confidence whatever in any drug treatment of tuberculosis, except for the relief of symptoms. I have had no personal experience with the tuberculin treatment. What I have seen of it, however, has been most disappointing, for it has seemed to me that it did more harm than good. My impression is that it is being used much less at present than it was a few years ago.

TUBERCULOSIS IN CHILDREN FROM THE STAND-POINT OF THE ORTHOPEDIST.

BY JOEL E. GOLDTHWAIT, M.D., BOSTON.

It is hard to know what to say at a meeting of this sort, speaking as an orthopedist, on a subject as general as this. You certainly do not wish detailed accounts of the local treatment of

bone and joint disease, and a few general statements of principle seem best to meet the need. The orthopedist has quite generally come to recognize that tuberculosis of bones and joints is due very largely to low general resistance of the individual. This being the case, we have two distinct features to observe in our treatment. One is to treat the part locally where the disease manifests itself, and the other is to see that everything is done that is possible to improve the general condition of the individual. The time was when the wards of our children's hospitals were filled with patients having hip or spine disease where the entire emphasis was put upon the treatment of the local condition. We have gone far beyond that point. The general treatment should receive at least equal attention.

It seems to me that we can pass over the local treatment by saying that in tuberculosis of the bones or joints, the things that the orthopedist aims to do are first to prevent deformity, or correct deformity if it has already occurred, and second, to put the part in the position of physiological rest—then allowing function in so far as the part will tolerate it. Anything that the individual can do with a diseased part (the individual, not someone else) we need have very little fear of doing harm. If the child can walk about once, the part is properly protected—let him walk about. If it is very acute, the child will instinctively not walk about. As fast as the child is able to use that part, it is to be encouraged. Use stimulates circulation, encourages bone repair and does the very thing we ought never to lose sight of—which is to stimulate the cells about the diseased portion, so that they will be stronger and able to control the disease rather than to weaken those parts by too great inactivity.

For the general condition the things which we are now doing have for their purpose the increasing, in so far as is possible, the general resistance and therefore the more perfect control of the local manifestation of the disease. This applies not only to tuberculosis, it applies to all sorts of infections,—the principles are practically the same. The thing that has helped us most in this connection and has given us something that we can speak about definitely because it is easily checked, has to do with the way the diaphragm is used. It seems to me that this is one of the most important single features of the physiology of the human being. If the diaphragm is down at the level of the twelfth rib and does not move—the circulation of the abdominal organs must suffer. Normal respiration involves the diaphragm and the normal circulation in the abdomen demands the same thing. Ideal respiration means the diaphragm high with slight movement of the chest—slow respiration and slow pulse. The diaphragm not only helps in the respiratory development, but it also pumps the blood from the abdomen and

the legs back to the heart. There is no other mechanism to accomplish this. With the diaphragm low, the circulation as well as the respiration will be interfered with and the general vitality will suffer.

Until you get the diaphragm so that it acts freely, you have not done all that you should do to improve the general resistance of the individual.

In trying to build up your individual to the best health—in trying to bring up their reserve so they can avoid tuberculosis—you have tangible things which you can check. Certainly there is more than just the microscope or the stethoscope in understanding these conditions.

Training for this physiological test is the sort of thing our preventiva should be doing. Get the children to stand properly. They will look better, but they will be more normal physiologically, and have greater resistance to tuberculosis or any other disease.

TUBERCULOSIS IN CHILDREN FROM THE STAND- POINT OF THE INTERNIST.

By HENRY D. CHADWICK, M.D., WESTFIELD, MASS.

IN considering the subject of tuberculosis in children it is necessary to divide them into groups as this disease varies very much in its manifestation according to the age of the child. There are three distinct types of tuberculosis in children:—the general or infantile, the hilum or juvenile, and the apical or adult form.

The infantile form in its primary stage assumes the characteristics of an acute, infectious fever, and progresses rapidly to a fatal termination, as general miliary tuberculosis, meningitis or bronchopneumonia. This is the usual course when infection occurs before the age of two years. From this age on the cause of infection is gradually modified by the production of a steadily increasing immunity. The tissues gradually acquire the power to react and the bacilli become fixed in the lymph nodes or more rarely in the epiphyses of the long bones or in the bodies of the vertebrae. After children have reached the age of five they rarely develop the infantile type of tuberculosis.

From five to twelve the lymphoid type of tuberculosis largely predominates. This period is a golden interval of low mortality between the infantile form on the one hand and the adult pulmonary form on the other, both of which have very high death rate. This tendency to focalize in the lymph nodes is the outstanding characteristic of juvenile tuberculosis. This was very apparent a few years ago when cervical tuberculous adenitis was such a common affliction in the children that came to the surgical outpatient departments. It is not so today largely because of the activities of the throat specialists in removing adenoids and diseased tonsils. Also the dentists must be given some of the credit because of the progress of dental hygiene.

Only comparatively recently, however, has the rôle of the tracheo-bronchial or hilum glands been given serious consideration in relation to the tuberculosis problem. As the lymphatics of the throat drain into the cervical glands, so the lymphatics of the lungs converge at the hilum and drain the entire pulmonary area into the tracheo-bronchial lymph nodes. There is this important difference however; the cervical glands only drain a small region, the tracheo-bronchial lymph nodes become the converging point of all bacilli that reach the lymphatics of the lungs, either by inhalation or through the pulmonary circulation that may take up infection from any part of the vascular system. There is, therefore, little chance for this group of glands in any individual to escape infection as long as tuberculosis is the universal disease that it is today. Fortunately the bacilli are so few in number or they are low in virulence or the individual's immunity is sufficient to prevent active disease in 70% of the people.

Pathologists are not yet in agreement as to whether the first lesion occurs in the lungs or in the tracheo-bronchial nodes. Krause has demonstrated that animals inoculated with tubercle bacilli exhibit foci of tuberculosis in the tracheo-bronchial nodes even when the lungs are free from disease. Furthermore, we do know that whenever the lungs show a tuberculous lesion that the tracheo-bronchial nodes are always involved. Most important of all to us is the fact that tuberculosis can be demonstrated in the glands of the hilum before any pulmonary lesion is large enough to be recognized by any method of examination now available.

Apical lesions or the adult type of tuberculosis rarely occur before the age of twelve years. After this age it is met with increasing frequency until the sixteenth year, when it becomes the usual type. The juvenile form after this age is rarely found as active disease. The healed hilum lesions are, however, often seen by x-ray or post-mortem in adults.

It is most important to recognize hilum tuberculosis when it is confined to the lymph nodes because this tissue has a tendency to keep the foci circumscribed. The resistance to tuberculosis between the ages of five to fifteen is greater relatively than at any other age period. Arrest or cure can reasonably be expected if proper treatment is carried out at this time.

There is a transition period due to the developing immunity between the ages of two to five, when either the infantile or juvenile type of tuberculosis may prevail. It is a dangerous period in an infected child's life. The disease is masked more completely than it is at later years. The child is usually well developed and nourished and of good color. Localizing symptoms may be delayed and there ensues an anxious period when the physician is puzzled to know

the cause of the occasional reoccurring febrile attack. Is it due to tuberculosis, and if so will the tubercle focalize in the head of a long bone, in the vertebral column, in the peritoneum, in the intestines or in some group of lymphatic glands? Those are some of the questions that a clinician has to answer.

Again we have another dangerous transition period after the child passes the age of twelve. Something as yet unknown to us occurs during the age of adolescence that influences the course of tuberculosis. The cases one sees of involvement restricted to the region of the hilum become fewer and the number of apical or adult type of tuberculosis increases as the patients approach the age of sixteen. It occasionally happens, but it is extremely rare to find a case of active hilum tuberculosis in an adult without apical lesions.

Juvenile tuberculosis involves the lymphatic glands at the hilum and the adjacent peribronchial tissue in its early stages. If the disease progresses the deep parenchymatous tissue between the trunks of the bronchial tree becomes invaded by infiltration. There may be peribronchial thickening with beading along the trunks that extend into the second and third interspaces.

Adult pulmonary tuberculosis involves the apices and the peripheral parenchymatous tissue. If one bears in mind this difference in the pathology of the two types of disease it will aid materially in diagnosis. The physical signs are different because in one the focus is superficial and in the other it is deep. Furthermore, in one the alveolar structure of the lung is involved and in the other the lymphatic tissue. Auscultation therefore does not give any positive information in early tracheo-bronchial tuberculosis. As the disease progresses and invades the deep parenchyma and peribronchial tissue changes in the breath sounds are sometimes heard in the infraclavicular triangle and along the vertebral border of the scapulae. Râles are not heard in hilum tuberculosis; the structures in which râles are produced, namely, the smaller bronchi and alveoli, are not involved until the pulmonary or adult type of tuberculosis is developed. If râles are numerous in any part of one or both lungs of a child from five to twelve they are probably due to some non-tuberculous infection, such as bronchitis, asthma, bronchopneumonia or abscess. If the râles are due to pulmonary tuberculosis, it is a case in the advanced stage, which fortunately rarely occurs in children of this age. One should not expect to elicit râles in early juvenile tuberculosis; when heard they should be regarded as negative evidence and should be considered due to non-tuberculous causes unless enough positive signs and symptoms of tuberculosis are present to justify such a diagnosis.

Percussion, however, is of great value in determining consolidation at the root of the lung. One must develop a careful technic to be of serv-

ice in revealing changes in the deeper structures of the lung. The child to be examined should be standing with shoulders slightly sloping forward with all muscles of the shoulder girdle in complete relaxation. Light percussion must be used with dependence for values placed more upon the tactile sense than upon the sound produced. It is always better to begin from below and progress upward. The reason for this is that the bases are seldom diseased and one can in this way perceive the normal resonance first for a standard and thus more easily detect any abnormal changes in the upper part of the lung. It should also be borne in mind that in children with active tracheo-bronchial nodes disease there is a reflex condition that tends to produce a chronic spasm of the muscles covering the upper part of the thorax posteriorly. This may be sufficient to change the percussion note enough to simulate dullness due to tuberculous infiltration of the apices. As a check, however, upon such an erroneous interpretation, one finds in such cases that the resonance is normal over the apices anteriorly and râles are not present.

SYMPTOMS.

In making a diagnosis in children great significance must be placed on symptoms which are an evidence of tuberculin toxæmia. In the order of importance these symptoms are fatigue or weakness. This is the first and most frequent of symptoms of onset. It is exhibited often as a change of disposition. A sunny, happy child becomes nervous and fretful, or an active, energetic one becomes languid and listless. Games no longer interest them and school work that was formerly enjoyed becomes a hardship. Light mental or physical efforts tire. Lack of appetite, failure to gain, or—more significant—loss of weight; tendency to profuse perspiration; fever. In hilum tuberculosis the toxæmia does not produce continuous fever. It occurs only after unusual exercise or fatigue from any cause. It is transitory. An afternoon temperature that does not go above 99.6 may be considered within the normal limits. A temperature of 101 or more is usually due to some non-tuberculous cause. It should be remembered that tuberculous disease of the lymph nodes or pulmonary tissues when not accompanied with pyogenic infection does not produce a marked rise in temperature. A purely tuberculous disease produces only a low grade of fever and then only when an increased amount of tuberculin is absorbed, as a tuberculin tolerance is gradually acquired. We must not, therefore, consider the absence of fever to contraindicate juvenile tuberculosis. Febrile attacks are infrequent, long fever-free periods are the rule.

A child's pulse is so erratic and normally so much higher than in adults that it is of no value in early diagnosis.

TUBERCULIN TEST.

We have found the intradermal tuberculin test so much more reliable than the Von Pirquet cutaneous method that we are using it exclusively. Absorption is certain and the dose accurate in each case. We give .01 m.g. of tuberculin intracutaneously for the first dose. If there is no reaction a second dose of 0.1 m.g. is given.

PREVIOUS HISTORY.

The exposure of a child to tuberculosis in the home, if long continued, is evidence of great weight in so far as it indicates the probability of massive and frequent infection. Such a child should be provided with excellent hygienic surroundings and care, even if there are no symptoms of disease. The lack of family history, however, as regards exposure to tuberculosis in the home, is of little value and should have no negative weight in diagnosis if there are definite signs and symptoms of disease. Out of a series of 200 children in our care 34% gave no history of intimate contact with any case of tuberculosis in the home.

DIAGNOSIS.

The points upon which a diagnosis of juvenile tuberculosis must be based are these:—

1. History of frequent colds or predisposing causes such as measles, whooping cough, and influenza. These diseases lessen the resistance to infection and tuberculous disease frequently follows in their wake. Also the frequent association of phlyctenular disease and serofoloderma with hilum tuberculosis should always be kept in mind.
2. Symptoms of tuberculin toxæmia, viz.—fatigue, malnutrition, anorexia, febrile attacks.
3. Exposure to tuberculosis in the home.
4. Positive cutaneous tuberculin test.
5. Evidence of enlarged tracheo-bronchial lymph nodes and infiltration or thickening of the adjacent tissues as demonstrated by physical signs and confirmed by roentgenogram.

In conclusion I wish to emphasize the point that juvenile tuberculosis is a manifestation of primary tuberculosis, apparent only in the lymph nodes and deeper tissues at the root of the lung. The adult type is a manifestation of tuberculous disease involving the superficial parenchymatous and peribronchial tissues of the lungs. The tissues involved are radically different in structure. The way in which they react to disease is distinctive. Therefore when we examine the chest of a child we should not expect to find râles and other signs of pulmonary tuberculosis. We should look carefully for evidence of bronchial adenitis. When we find enlargement of the bronchial lymph nodes with thickening of adjacent tissues, accompanied by symptoms of a tuberculin toxæmia, together with a positive intracutaneous test, a diagnosis of hilum tuberculosis should be made.

TUBERCULOSIS IN CHILDREN FROM THE STAND-
POINT OF THE SURGEON.

By LLOYD T. BROWN, M.D., BOSTON.

IN dealing with such a subject as Surgical Tuberculosis one finds himself confronted with problems, the solution of which is very difficult. There are many points to be touched upon, any one of which could well occupy the entire time of such a gathering as this. It is out of the question to discuss all the forms of non-pulmonary tuberculosis and I shall leave to people better qualified than I the question of the glandular forms, such as tubercular cervical adenitis, tubercular peritonitis, etc. Perhaps the first and the most important point to be mentioned is that surgery in tuberculosis must be approached with a very different point of view than in almost any other condition. We long ago learned that it is impossible to entirely eradicate by any surgical procedure all of the tubercular process, but we have also learned that if the proper after-care can be given it is not necessary to entirely remove the focus. Therefore, it can be seen that the surgical procedure in itself is only an incident in the treatment of the disease and that the real problem is not the operation, but what facilities can be found for the proper preoperative and post-operative care of the patient.

In order to emphasize this fact that the surgical treatment of tuberculosis, referring to bone tuberculosis, is in reality a very small part of the treatment, the following figures are quoted from the last three annual reports of the Children's Hospital:—492 cases of bone tuberculosis were admitted to the wards because care at home or in the Out Patient Department had not sufficed. Of these 492 cases, only 55 cases were operated upon, all but 4 of which were for simple drainage of abscesses or similar procedures. These four exceptions were operated upon for spinal immobilization.

The question of the incidence of bone tuberculosis was also a difficult problem and one at the present time impossible to answer. Although a law has been in existence since 1907, requiring the reporting to the State of all cases of bone or non-pulmonary tuberculosis, the physicians and hospitals of this State have neglected this duty so completely that there are no such statistics available for the non-pulmonary as there are for the pulmonary cases. Hospital reports give most inadequate information on the total number of cases in the State, but are very surprising in showing the number of cases which do come to the clinics. As quoted above, in three years 492 cases entered the wards of the Children's Hospital. At the Massachusetts General Hospital the Orthopaedic Department during the years 1920-21 treated 291 cases of bone tuberculosis, 81 of which were children and 210 adults. Of these cases, 79 adults and 25 children had tuberculosis of the spine. Of the 192 Children's

Hospital cases 243 were tuberculosis of the spine. Tuberculosis of the hip was next in frequency of occurrence at both hospitals. At the Massachusetts General Hospital 41 adults and 34 children, and at the Children's Hospital in three years 161 cases of tuberculosis of the hip were recorded. Knees were next in frequency, and the remaining cases were scattered all over the body. Since, as mentioned above, the time allotted to this paper is so short, it is impossible to deal with more than one condition. Therefore it is considered advisable to take up that condition which at the present time is most frequent in occurrence and which from force of circumstances in the majority of hospital cases is very inadequately treated in both children and adults. I refer to tuberculosis of the spine. That the occurrence of tuberculosis in the spine is the most common site of bone tuberculosis is shown by the above figures and also by figures found at the Rizzoli Orthopaedic Institute in Italy, where from the years 1907-1919, 45.5%, or 1271 out of 2790 cases of bone and joint tuberculosis, were in the spine.

The bacteria responsible for this condition are, of course, the tubercle bacillus of either the bovine or human form. When it is considered that 25 to 40% of the milk producing herds in Massachusetts show positive tuberculin reactions, the recent passage of the law by the Legislature which allows the State to make use of Federal Aid in cleaning up our herds, is a matter of great importance. In New York City, where the control of the milk situation is very carefully carried out, the results have been marked. A recent letter from an orthopaedic surgeon at the Hospital for the Ruptured and Crippled in New York says that twenty-five years ago the tubercular cases were the most common ones in the clinic, while at the present time they are among the least common.

The most valuable and careful work that is being done throughout the state in educating the people how to prevent infection from tuberculosis cannot be too highly endorsed, and it is the duty of every physician to further the cause in every way possible. Since, however, there will always be a certain number of cases to be looked after, it is of the utmost importance that the methods of treatment which tend to give the best functional results should be understood and carried out by all.

Here is a photograph showing the results in three girls of the treatment that has been used in this country for many years. This treatment is the supportive and ambulatory method. By this is meant recumbency as long as there are any acute symptoms; after this, plaster jackets and braces and allowing the patient to be up and around. Two of these girls had their spines immobilized by the operative method of putting a section of their tibiae into the spinous process, the so-called Albee operation. The result is what you see here. Any other form

of treatment was impossible in these cases because there were no places where recumbency under proper supervision could be carried out. That recumbency at home in the average hospital case is impossible can be seen when one finds in the hospital records such notes as this: "Patient comfortable on frame. Mother says she finds the child crawling or walking around with the frame on its back."

If the ambulatory treatment gives such results, what then is the ideal treatment we should all strive for? The literature at the present time is filled with articles about this problem. It must be remembered that tuberculosis in a child or adult is a serious condition, and although the patient may become free of symptoms with two or three months of recumbency or after an operative immobilization of the spine, this does not mean that the disease has been cured. If one follows these cases for a period of years a recurrence of the condition is very commonly found years afterwards, and what is still more important the tubercular infection may recur in another part of the body.

The method of treatment advocated by such men as Sorrel and Calvé at Bercy-sur-Mer in France, where there are two hospitals with a capacity of more than 2,000 beds just for the city of Paris alone, must be considered with great care. Rollier, the strongest advocate for heliotherapy, or the sunlight treatment, also gives us much food for thought. Recent letters from Canada and New York from men who are dealing with these conditions all practically agree as to the ideal treatment.

This treatment differs in children and adults. In children the bones are soft and rapidly growing. The disease tends to destroy the vertebrae and the intervertebral disc. The process of healing consists in the calcification or laying down of lime salts in the diseased areas. This process is a very slow one, requiring months or years. Although all painful symptoms may rapidly disappear with recumbency, the pathological process is still present, and if the child is allowed up, even with the supportive jackets or braces, the superimposed weight tends to cause pressure on the slowly healing pathologic process and the result is either a recurrence of the symptoms or, as in the cases shown, an increase in the deformity. The operative immobilization of the spine in children, as brought out by the investigation of the commission appointed by the American Orthopaedic Association to look into this subject and as seen in these two cases, does not in itself prevent further deformity.

It is our belief, therefore, that in children a period of recumbency either on a frame or in a plaster shell should be carried out for 2-3 years, preferably 3. This means that during this time there should be no superimposed weight on the spine, such as comes from sitting or standing up. At the end of this time, if the x-ray picture shows signs of new bone formation and there are

no signs of acute disease, the child may be allowed very short periods of being up, provided the spine is given sufficient support. At least two years more of gradually increasing weight bearing is necessary before it is safe to allow complete freedom, and some men think supports should be worn until adult life. With such a plan of treatment we should expect to be able to prevent such deformities and such cripples as these. And let me add here that these three are only a very small proportion of the number coming to our hospitals and Cripple School. This may seem like a very long time, but these children here, like almost all the others of their kind, are still coming to the hospitals for treatment and are still wearing braces 12 to 15 years after their treatment was started.

In the adult cases conditions are different. We no longer are dealing with growing bone and we are dealing with a group of cases in which the time element is of great importance. For this reason if anything can with safety be done which will shorten the time element, it is advisable. With our desire to shorten the time element, however, we must not forget, as Calvé says, that an adult with Pott's disease is tuberculous with a grave focus and is liable to develop other foci of the same nature, and that the general treatment is the main thing.

It has been stated, and experience has proven it to be so, in selected cases, that a stabilizing operation on the spine, either the fusion operation as described by Hibbs, or the bone graft of Albee, or the bone periosteal flap method of Delagenière, may be a successful procedure. The selection of cases, however, is very important. A series of cases at the Massachusetts General Hospital has brought out the fact that nearly half of the cases operated upon had more than one tubercular focus. In some it did not develop until five years after the operation and in others it was discovered first. Any case with an acute or even subacute pulmonary condition is a poor operative risk. One such case developed a rapidly fatal miliary tuberculosis after the operation. Such possibilities as two separate and distinct foci of disease in the same spine must be considered. This occurred six times in a series of 29 cases at the Massachusetts General Hospital.

As has been said before, however, the operative treatment which is distinctly inadvisable in children, must be considered merely as an incident in the treatment of the adult. With or without the operative treatment, heliotherapy and recumbency, which means the removal of all superimposed weight on the spine, are the most important features. Without operation, recumbency is necessary for at least a year, and this is followed by a jacket or brace for two to three years more. With operation, the time of recumbency may be shortened to six months, but the jacket or brace support should be worn for a year or two. Some patients report that they are still

wearing it for four or five years after the operation because they feel safer.

With these necessities for treatment in mind, what are the facilities throughout the state for affording such treatment? At the present time there is not a single state or city institution which is properly equipped to carry out effectively such treatment. There are one or two private charity hospitals or homes which are able to take a few children, but practically no adults. There are some institutions which are willing to take a few such cases, but their equipment and personnel is such that they do so largely under protest. It is for this reason, gentlemen, that our results in the treatment are not what they should be. Rollier in 1913 reported 86 per cent. cures in 198 cases, but there are few people of the total number afflicted with spinal or bone tuberculosis who can afford the luxury of such a place as Rollier's. DeBrumer in 1921, speaking of the results in patients who were treated under the most unfavorable home conditions, says the mortality rate was 42 per cent. Although he gives the mortality rate as 42 per cent., he says nothing about the cases such as those which are still drifting into our clinics after 12 or 15 years of treatment, and who, from the economic point of view, are such a tremendous loss to the community.

In conclusion I should like to bring out certain points:

1. That at present we have no accurate statistics in this state as to the number of non-pulmonary cases of tuberculosis, and that this lack is due to the physicians and hospitals of the state failing to report their cases. This can and should be corrected.
2. That surgery in tuberculosis is and should be the exception, and that it should always be made only an incident in the general and necessarily prolonged treatment.
3. That in children operations for spinal immobilization are not advisable and without the proper postoperative care in adults do not give the results claimed.
4. That in tuberculosis of the spine in both children and adults the ambulatory and supportive treatment has not given satisfactory results.
5. That in children the ideal treatment is recumbency for at least two to three years, followed by carefully observed and protected weight bearing for two years more.
6. That in adults in selected cases the operation for spinal immobilization may be advisable if it can be followed by at least six months' recumbency and a year or more of supportive treatment.
7. That there are no hospitals in the state with an equipment or a personnel which can adequately carry out the proper prolonged treatment of recumbency and heliotherapy.

8. That it is the duty of the medical profession of this state to urge our legislature to provide as adequate opportunity for the treatment of non-pulmonary tuberculosis as is provided for the pulmonary cases.

THE X-RAY IN THE DIAGNOSIS OF PULMONARY TUBERCULOSIS.

BY SAMUEL W. ELLSWORTH, M.D., Boston.

It is not proposed to describe the technical details of the use of the x-rays by means of the fluorescent screen and radiogram, but rather briefly to indicate some of the possibilities and limitations of this method of examination in the study of tuberculosis of the lungs.

The screen serves best in observing the movements of the thorax, diaphragm and heart during respiration.

The film or plate gives a permanent record of the details of light and shade.

The stereoscopic films afford perspective vision and position of shadows.

The lung fields, distended with air, offer but slight resistance to the passage of the rays and present a brilliant background for the study of the more opaque tissues. The depth of the shadows cast is dependent upon the density and mass of the structures traversed by the rays.

We have, then, a remarkably accurate means of detecting the presence or absence, the position, extent and the character of pathologic conditions in the lungs. Pathology is represented by abnormal densities shown on the film or screen, and no other means have been found which will give nearly so accurate a picture of lung pathology during life as the x-ray film.

Slight abnormalities in density require careful study to detect; the gross lesions are often easily observed. Both types demand especial discrimination to determine the probable etiology.

There are but few diseases which justify a diagnosis from the x-ray observations alone. Interpretation of the x-ray findings demands a careful analysis of the data observed; definite diagnosis or etiology can be made only by a coördination of the history, physical signs and symptoms and laboratory data.

It is necessary to emphasize that x-ray observations concern not merely one spot of density, but rather the entire lung fields, the level of the diaphragm, the excursions during respiration, as well as the position and movements of the heart.

If we accept the statement that every lung shadow may represent one of many pathological lung lesions, the necessity of careful differentiation is obvious.

Doubtful cases may require repeated examinations; this is especially true in many cases of early pulmonary tuberculosis. To appreciate the early and slight lesions of tuberculosis requires

some degree of familiarity with the normal lung picture, and the denser shadows should be identified with the gross specimens and sections from the post-mortem table.

Tubercular infection in some form occurs with such frequency, that it is now recognized as an almost universal condition.

The suspected or doubtful case is the great medical problem, where the delayed or uncertain diagnosis fails to impress the patient and measures to control are neglected until the disease is well established. Not infrequently the x-ray will disclose other conditions, such as heart disease, rather than the suspected tuberculosis, or, on the contrary, no evidence at all of pulmonary lesion.

The x-ray examination as an accessory to, and combined with the clinical examination, enables one to make an earlier diagnosis in many doubtful cases of disease of the chest, with an accuracy not obtained heretofore, and in my opinion, no medical examination can be considered as completed which has neglected this method of examination.

DISCUSSION.

DR. EUGENE R. KELLEY, Boston: I think we will all agree that this is perhaps the most interesting session of the Tuberculosis Section for several years. I think the officers of the Section are to be congratulated on the happy expedient they struck of having a symposium on some of the more interesting phases of tuberculosis in children.

I want to say two or three words on points that interested me very much in the papers presented this afternoon. I wish to reiterate what Dr. Brown brought out in reference to the very poor reporting of non-pulmonary cases of tuberculosis. It is an old subject with the State Department of Health and probably we are very much to blame for it not being better reported. But frankly, we have been at a little bit of a loss as to how to bring about better cooperation. The medical profession has responded very well, I think, on the reporting of pulmonary tuberculosis.

If you look back over the statistics, you will find in the year 1915, when there was a resolve passed looking into the question of facilities for non-pulmonary cases, there was very much better reporting than there had ever been before or since. The reporting of non-pulmonary cases is one of the things that needs to be brought to the physician's attention. Another thing that accounts in a considerable degree for poor reporting is the failure on the part of institutional authorities to realize that the legal obligation rests the same on them as on the individual physician to report a case. It has happened in four large institutions a few years ago you could collect off their records more cases of non-pulmonary tuberculosis than were reported in the whole State. Of course, the answer to that is that the institution men leave it to the family doctor, who knew the case before it went to the institution, to make the report. The law puts the same obligation upon the institution as upon the physician.

I was also very much interested in the percentages that Dr. Morse gave, of diagnoses at the Children's Hospital, in the house service. It is a rather curious coincidence—the percentages, as I roughly calculate them, being about 8 per cent. That is just about the percentage of diagnoses that we are making in the special examination clinics for children which we are holding in various parts of the State. The point

is that both of those groups represent a sort of preliminary rough sifting process. In the hospital, they are there because they are sick. In the groups as taken in the special field clinics, they are selected because they have shown some of the obvious symptoms that Dr. Chadwick laid stress upon. They are all school children, who are picked out as the obviously underweight, very much fatigued, or the children who were showing both those symptoms plus an inability to keep up in their school work.

The statistics of diagnoses made to entire number of children seen for the Out-Patient Department service of the Children's Hospital struck me as being poorer than they theoretically ought to be. Probably they cannot adequately diagnose tuberculosis in children when they see it before them in the Out-Patient Department service at that institution or any other institution's out-patient department. That is inevitable. It would be impossible under those conditions to establish positive diagnoses in these cases, where it could be done under more favorable conditions for longer observation.

DR. RICHARD L. MILLER, Boston: I have been very much interested in tuberculous cervical glands, and am glad to say just a few words. I have had the privilege for a long time of working with Dr. Bartlett in the non-pulmonary tuberculosis clinic at the Massachusetts General Hospital, where we have seen hundreds of cases of enlarged cervical glands. In the first place, I agree with Dr. Morse that it is, at least at the outset, a local process. We think that it seems to confer a certain amount of immunity, and that pulmonary tuberculosis is not common in those who have cervical tuberculosis.

There has recently been some work done in investigating tuberculosis of the lungs, more especially the apical pleura, by x-rays, to determine whether tuberculous infection can come in through the tonsils and adenoids and via the cervical glands to the apex. Certain men have drawn conclusions as a result of these x-ray examinations that that is possible, and is not uncommon. The anatomy of the cervical lymph glands does not, in our opinion, make that possible, because they do not drain to or very near to the apices of the lungs, but into the jugular trunk, which empties into the vein on the right and into the thoracic duct on the left.

Dr. Morse says that the one treatment *par excellence* for these glands is surgery. Our conclusion has been that surgery is not primarily the treatment of choice. Surgery is a thing that must be put off until you have tried other things, though acute fluctuant abscesses must be operated on. The average case of tuberculous glands should not at once be handed over to the surgeon, and though our business is surgery, we do not believe in it to the exclusion of other methods.

Certain writers have recently said that the x-ray will cure most of them, but in our experience it will cure only a few. We have been working a certain amount with artificial light, the mercury vapor quartz lamp—the so-called Alpine Sun Lamp. This does a great deal of good, especially when there are discharging sinuses, and we have just this spring had several most remarkable results with it.

We have also used for a long time tuberculin, and we are perfectly convinced that in a fair number of cases it does a great deal of good. We have seen certain cases in which the glands absolutely melt away under tuberculin. The difficulties of its use are that a lot of people do not understand it—they give too much—they may give too little, or the patients do not follow treatment conscientiously. Tuberculin carefully given and conscientiously followed out, supplemented with hygiene, and perhaps with the Alpine lamp when it is deemed wise, and heliotherapy, will cure a good many cases. I think it is an im-

portant thing to bear in mind that surgery is not primarily a proper way to treat tuberculous glands of the neck.

Fig. 8. A. KNOX, New York: I want to thank you, Mr. Chairman, for calling on me. I consider myself one of the most fortunate individuals in the world. I came to Boston on an entirely different errand, and now I am treated to a lesson in tuberculosis. I have learned already much that was worth coming for. I feel at a loss to know what I can offer to you that has not been presented to you before or that will not be offered to you later. Still, since my friend of many years, your distinguished Chairman, Dr. Otis, has asked me to address you, I will venture to discuss something which might perhaps deserve the name of being new. I have spoken of it before and have called it "A Physiological Adjuvant in the Rest Cure of Pulmonary Tuberculosis."

Ever since Dettweiler devised the rest cure in a reclining chair in the open air as a means of accomplishing the cure of pulmonary tuberculosis, the idea of exercise in the open air as a therapeutic measure in tuberculosis has been abandoned by the majority of physicians. Many attempts have been made by numerous experimenters to add local rest for the tuberculous lung to the general bodily rest treatment. Denison and Szwed suggest mechanical restrictions by means of adhesive plaster or belts. All report good results. I believe you can accomplish something, but not a great deal. Of course, with the advent of artificial pneumothorax, we thought we had realized the ideal in putting the infected lung at rest. But, alas! we cannot get in every time. There is a vast difference of opinion as to the advisability of artificial pneumothorax in all cases. I, for one, cannot advocate it in all cases. We have the pleuritic adhesions to overcome. The operation devised by Jacobson, who, with the aid of a thoracoscope and a long cantery protected by a cannula, divides the pleuritic adhesions, may help to diminish the number of cases which have heretofore been considered unsuitable for artificial pneumothorax. In dividing the pleuritic bands with the bistoury or even with the electric cantery, there will always be some danger of coming across very vascular adhesions or such extensive ones that there may be danger of hemorrhage and rupturing the lung. The operation has thus far yielded a rather high mortality so that it must be restricted to a very few cases.

Comparative physiology teaches us that the slow breathing animals are less susceptible to tuberculosis than the fast breathing ones. The horse breathes only 8 to 10 times a minute—the cow 15 to 20 times. The turtle breathes so imperceptibly that you cannot perceive it. This, at any rate, impelled me to make a study of restricted diaphragm breathing. I tried it on myself first. To my surprise, I found I could very comfortably breathe and exist with six and eight respirations a minute, limiting them to the diaphragm. Still, I was coward enough not to publish anything until I had some authority. I consulted Prof. Lusk, of Cornell, and asked him if there was any danger of my increasing the accumulation of carbon dioxide. He wrote me that it would not do any harm; that if I had too much carbon dioxide, nature would call for more oxidation. Through the courtesy of Prof. Lusk, I was permitted to make some spirometric tests at the Russell Sage Institute. One of his assistants kindly lent himself to the experiment. After I had demonstrated to him how he could diminish the number of respirations to five per minute, and limit them to the basal portions of the lungs, he was surprised to find with what comfort he could do it, and thought he could do it indefinitely. I found he took in more air than ordinarily. In ordinary respiration, his tidal volume was 600 cc. per respiration. I observed that the volume of tidal air in

creased considerably while he was lying in a recumbent position, breathing through the tube of the spirometer. I tried it on patients. I did not publish anything. I made my report to the Surgeon General of the U. S. Public Health Service, to which I am attached. It was returned with approval. The results were these: In advanced cases, I noticed, after a few months' trial, a tendency to fibrosis. In the moderately advanced cases, I noticed a decrease in pulse rate and a decrease in cough.

In conclusion, two observations—one on hemorrhage, the other on psychology. Two patients of mine who had had bloody expectoration and who stated that it always lasted many days, assured me that this quiet and diminished breathing shortened the usual duration of their blood spitting considerably. I had one man, a very intelligent gentleman, whom I had advised to use this restricted diaphragmatic breathing. After twenty-four hours he sent a messenger to me asking me to come at once, that he could not stand it any longer. I could not go at once so I sent my assistant. He came back and said the man was very unhappy and he thought I had better go and see him. I went as soon as I could. The patient said to me: "Ever since you told me I should restrict my breathing I am a most unfortunate individual; I am unhappy; I cannot stand it any longer." I said: "You take deep breaths any time you want to. I did not mean to stop you from breathing deeply." The next time I went he said: "Ever since you told me I could take a deep breath I do not feel the need of it any more."

Try it on yourself and your patients. I hope you will have the same success, and better, than I have had, but, as your distinguished townsman has told you, it is an important thing to take all things into consideration. As you all know, the majority of tuberculous lesions are confined to the upper region of the lungs. By giving them a rest you will be surprised how much good you can do your patient—and to do good is our calling.

*Director, Sias Laboratories, Brookline, Mass.,
Instructor in Public Health Laboratory Methods,
Massachusetts Institute of Technology.*

PART 2.

WAS-ERMANN TESTS — A COMPARISON OF REPORTS FROM SEVERAL LABORATORIES ON IDENTICAL SPECIMENS.

The method first adopted for comparing Was-ermann tests was to pool the left-over serums from positive, negative or doubtful cases and then divide into a sufficient number of specimens to supply the laboratories. The first series had two positive, two negative and two doubtful specimens.

Here there is complete agreement on strong positives and on straight negatives. Border

WASSERMANN TESTS—FIRST SERIES.

Lab.	Specimens.					
	1	2	3	4	5	6
1	—	+	+	—	—	—
2	Doubtful	—	+	—	—	Broken tube
3	—	+	+	—	—	—

7	—	—	+	+	a. c.	—
8	—	—	+	+	+	—

Specimens 1, 2 and 6 are identical. All agree except an a. c. report by Laboratory No. 3 on specimen 6. Specimen No. 5 was from pooled doubtful serums. It seems the pooled serums gave a stronger reaction than did the individual ones, since five out of eight laboratories report this specimen positive.

On the whole, the indications from these three series of tests seem to be that with a strong positive or with a straight negative specimen reports from reputable laboratories will agree, while with a weakly positive or doubtful specimen the report will vary from negative to positive, depending on the individual adjustment of the hemolytic system.

Comparative Tests with Specimens from Individuals.—In the discussion of the work done on pooled serums differences of opinion arose

which, it seemed, might be cleared away by running a series of tests on serums from individuals where the history was known. Dr. Hinton kindly agreed to furnish these serums from the laboratory of the Boston Dispensary.

Besides the Boston Dispensary laboratory, the following laboratories joined in the tests: Boston City Hospital, Boston Health Department, State Wassermann laboratory, Homeopathic Hospital Laboratory and the Sias Laboratory.

The serums were distributed Thursdays and tests were made Fridays, excepting in the Dispensary, which made the tests a day earlier.

In this series of forty-three tests there were twenty-three on which all the reports agree as negative; twenty of these have no history of syphilis; the others, Nos. 9, 22 and 31, are cases of treated syphilis.

There were five on which all agree as positive, Nos. 1, 3, 24, 25 and 30, all giving histories of syphilis.

There were seven on which there is practically agreement in the report of negative, the minority reporting doubtful or doubtfully weak positive, which the technician of the latter laboratory explains might as well be reported doubtfully negative.—Nos. 4, 8, 16, 17, 19, 34 and 36. Four with a negative history, two of treated syphilis and one where there is doubt.

There were two on which there is practically agreement on the report of positive, a minority worker reporting doubtful in one case and anticomplementary in the other. These are Nos. 11 and 32, both with histories of syphilis.

Thus, of the forty-three cases, or 258 tests, there remain but six in which there are any real disagreements.

Case No. 5, reported positive by five workers, negative by one, gives a history of syphilis, with at least twelve arsphenamines.

Case No. 7, reported positive by four, anticomplementary by one, negative by one, gives no history of syphilis, and was thought probably tubercular. In view of the Wassermann findings, the case is probably syphilitic.

Case No. 12, reported positive by four, doubtful by one, negative by one, has a history of two miscarriages and two arsphenamine treatments.

Case No. 13, reported positive by three, doubtful by one, (?) negative by one, and negative by one, gives a history of syphilis with thirty to forty arsphenamines.

Case No. 38, reported positive by three, doubtful by two, negative by one, gives a history of syphilis, with six positive and three negative Wassermans.

Case No. 42, reported negative by four, doubtful by one, positive by one, is evidently from the history a case of treated syphilis.

HISTORIES.

1. (14566)—Man, chancre twenty-five years ago. Treated for five weeks. Positive Wassermann.
2. (14585)—Janitor, sixty-six years old, who states there is no history of gonorrhoea or chancre. Negative clinically. Negative Wassermann. Diagnosis, flat-foot.
3. (14565)—Chancre sixteen years ago. Treated for one and a half years. Has had more than seventeen arsphenamines in the last three years, together with mercury and iodides. Previous Wassermans—positive, doubtful, doubtful, negative, positive, positive. Diagnosis, syphilis with tabetic symptoms.
4. (14583)—Jewish woman of twenty-seven with a diagnosis of tendon strain and no history of syphilis. Negative clinically. Negative Wassermann. Diagnosis, tendon strain.
5. (14548)—Storekeeper, forty-eight years old, denying chancre and other symptoms referable to syphilis and giving history of tuberculosis for four and a half years, now inactive. Three positive Wassermans followed by a doubtful and later a positive. During the course of these Wassermann tests has had at least twelve arsphenamines covering a period of three months. Diagnosis, not stated, but patient is now being given syphilitic treatment.
6. (14580)—Girl of eleven, whose parents are syphilitic. Three negative Wassermans for a period of three months. Diagnosis, the Wassermann tests taken to determine the presence of syphilis on the basis of parentage.
7. (14571)—Girl of eighteen years without stigmata of syphilis, showing ulcerated areas over the buttocks and over the arms, which are of questionable origin. Tuberculosis considered. Diagnosis, question of lupus.
8. (14588)—Married woman of twenty-four without history of syphilis. Wassermann negative. Diagnosis deferred.
9. (14559)—A married Greek woman of thirty-two who has been treated for syphilis here since 1916, having had a lot of salvarsan, mercury and iodides. Seven Wassermann reactions, all negative. Diagnosis, treated syphilis.
10. (14578)—Jewish woman of fifty without history of syphilis and a clinical diagnosis of torticollis. Wassermann negative.
11. (14595)—Child of syphilitic mother. Two positive Wassermans. Amount of treatment prior to Wassermann tests not shown in the record.
12. (14546)—Jewish widow thirty years of age with a history of two miscarriages. Positive Wassermann in New York and two injections of arsphenamines. Gives no history of primary or secondary lesions. Wassermann positive.
13. (14555)—Married man of forty-four, infected sixteen years ago. Negative Wassermann, doubtful Wassermann, lumbar puncture spinal fluid positive Wassermann, cells twenty-seven, positive gold sol, reaction, doubtful Wassermann, negative Wassermann, two positive Wassermans, negative Wassermann. Had had thirty or forty arsphenamines. Diagnosis, syphilis; tabo-paresis.
14. (14568)—Married American porter, forty years of age, treated for gonorrhoea. At present has acne. Wassermann negative.
15. (208)—Married Jewess, thirty years of age, without symptoms or physical examination of syphilis. Wassermann negative. Diagnosis deferred.
16. (191)—Married female, Portuguese, twenty years of age, with periostitis of the radius and enlarged epitrochlears, who has had six doses of salvarsan at the Boston Dispensary. Wassermann doubtful. Diagnosis, treated syphilis.
17. (193)—Italian farm hand, seventy years of age, without history or symptoms of syphilis. Wassermann negative. Diagnosis, epithelioma of the cheek.
18. (233)—Lithuanian married woman, thirty-nine years of age, who has had two miscarriages, but without any other symptoms referable to syphilis. Wassermann negative. Diagnosis deferred.
19. (206)—Italian bricklayer, forty-eight years of age, who comes with a history of having been treated for syphilis in Hartford four years ago. No physical examination taken. Wassermann negative.
20. (242)—Married woman of twenty-five, has had a medical examination; no history nor clinical evidence of syphilis. Wassermann negative. Diagnosis, psychasthenia.
21. (243)—Married Italian woman, twenty-three years of age, without history or clinical evidence of syphilis. Wassermann negative. Diagnosis, chronic pharyngitis, question of proctitis.
22. (197)—Female, thirty-eight years of age, with a history of syphilis dating back as late as seven years, who has had numerous doubtful and a few negative Wassermans, and who has had a lot of anti-syphilitic treatment, including arsphenamines. Diagnosis, treated syphilis.
23. (216)—American, thirty-nine years of age, complaining of a rash of four days' duration; also presents a penile sore of four days' duration; dark field shows no pallida. No previous evidence of syphilis. Wassermann negative. Diagnosis deferred.
24. (214)—Married American Negress, twenty-three years of age, with a history of primary seven years ago. Five positive Wassermans; large amount of syphilitic treatment. Diagnosis, treated syphilis.
25. (194)—Fireman, twenty-eight years of age, with a history of chancre a year ago. Amount of treatment not indicated on the record. Wassermann positive. Diagnosis, treated syphilis.

26. (238)—Married Irish woman, thirty-eight years of age, without history or clinical evidence of syphilis and with a diagnosis of sciatia. Wassermann negative.

27. (241)—Single machinist, twenty-four years of age, without history or clinical evidence of syphilis. Wassermann negative.

28. (236)—Married tailor, fifty-one years of age, without history or clinical evidence of syphilis, but with keratosis. Wassermann negative.

29. (234)—Married woman, forty-seven years of age, without history or clinical evidence of syphilis, presenting arteriosclerosis and associated conditions. Wassermann negative.

30. (382)—Teamster, twenty-six years of age, with a history of syphilis and three injections of arsphenamine. Positive Wassermann.

31. (386)—Single Italian, thirty-one years of age, with a history of syphilis nine years ago, who has had a large amount of arsphenamine and mercury, but no positive Wassermann since 1920. Wassermann negative.

32. (384)—married woman, sixty-one years of age, whose husband died of shock at forty-eight, who has had eight positive Wassermanns in the last two years and intensive treatment with arsphenamine and mercury. Diagnosis, treated syphilis. Wassermann doubtful.

33. (394)—Married teamster, thirty-eight years of age, without history or physical signs of syphilis; has boils. Wassermann negative.

34. (385)—Telephone operator, twenty-one years of age, with a history of syphilis five years ago and treatment; has had no positive Wassermanns in the last two years. Diagnosis, treated syphilis. Wassermann negative.

35. (383)—Negro, navy yard helper, nineteen years of age; has had gonorrhoea, but no history of syphilis. At present has scabies. Wassermann negative.

36. (398)—Italian married woman, thirty years of age, without history or symptoms of syphilis. Diagnosis, rheumatism. Wassermann negative.

37. (410)—Married teamster, fifty-six years of age, without history or clinical evidence of syphilis; now suffering with obesity and hypertension. Wassermann negative.

38. (389)—Italian barber with a history of syphilis and six positive Wassermanns and three negative Wassermanns.

39. (396)—Married Canadian woman, forty-two years of age, without history or clinical evidence of syphilis. Diagnosis, scabies. Wassermann negative.

40. (388)—Married Canadian woman, twenty years of age, without history or clinical evidence of syphilis. Diagnosis not given. Wassermann negative.

41. (415)—Jewish housewife, forty-four years of age, without history or clinical evidence of syphilis; suffering from obesity and constipation. Wassermann negative.

42. (390)—Married Jewess, twenty-nine years of age. Has husband and one baby with positive Wassermanns; she has had intensive treatment with arsphenamine and mercury; several positive Wassermanns, none positive, however, since 1920.

43. (411)—Salesgirl, sixteen years of age, without history or clinical evidence of syphilis, but who has neurasthenia. Wassermann negative.

Results.—Out of a total of 258 tests there are, then, but six flat disagreements, or 2.3 per cent., all but one of which are on cases of treated syphilis.

There are eleven cases (4, 6, 8, 9, 14, 16, 17, 19, 34, 36 and 42) in which one or more workers noted a tendency towards false positive results with the use of cholesterinized antigens, especially the State antigen, but in most instances there was sufficient evidence from other antigens to disregard these findings or to qualify them to the extent of giving a doubtful or negative report.

Acetone insoluble antigen with .1 cc. serum tends to give false negatives. (Cases 3, 5, 12, 13, 32 and 38.) With .4 cc. serum this is largely corrected. (Cases 3, 5, 12, 32 and 38.)

It is interesting to note how much closer readings are given with cholesterinized antigens when the two doses of serum, .1 and .05, are used as by Laboratory C.

On the whole, the tests indicate a high degree of accuracy in diagnosis, and strong agreement among different workers with the same specimens.

(To be continued.)

CANCER OF THE PROSTATE: A COMPARISON OF RESULTS OBTAINED BY RADIUM AND SURGICAL TREATMENT.

BUMPUS, H. C. (*Surgery, Gynecology and Obstetrics*, August, 1922), writes as follows:

The results obtained thus far by radium in the treatment of cancer of the prostate are inferior to those obtained by surgery.

The new methods of radium application indicate that in the future the results of the two methods will be the same.

Partial prostatectomy in cases of carcinoma occasionally proves to be a curative rather than a palliative procedure.

A combination of radium and surgery offers the best results.

[E. H. R.]

CONGENITAL PORPHYRIURIA, WITH HYDROA ESTIVALE AND PINK TELTH.

MACKAY and GARROD (*Quarterly Journal of Med.*, July, 1922) report a case of this rare and interesting anomaly, and discuss the literature. The patient, a boy of six, passed red urine immediately after birth, and began to suffer from hydroa at the age of three months. (Hydroa estivale characterized by a bullous eruption occurring in the warm seasons on parts exposed to light, and leaving scars.) The association of porphyria with hydroa has been noted repeatedly, and it has been shown that the injection of porphyrin renders the skin highly sensitive to light. It should be noted, however, that not all cases of hydroa have shown porphyria.

Fischer showed that in porphyria there is also porphyrin in the feces, though of a somewhat different chemical formula from uroporphyrin, both of which, moreover, are different in formula from artificial hematoporphyrin, though all three give very similar spectroscopic bands. Mackay and Garrod were able to confirm these results.

The occurrence of a deep brown pigmentation of the bones has been noted in several cases, but the authors are the first to report pigmentation of the crowns of the teeth, which were of a rosy pink color during infancy, changing later to deep brown.

They follow Günther's classification of porphyria into four classes—(1) acute toxic, following the use of trional or sulphonal, (2) acute, (3) chronic acquired, and (4) chronic congenital.

Although the origin of porphyrin from blood pigment seems certain, no signs of excessive blood destruction are found in the reported cases.

[W. T.]

REPORT OF THE AMERICAN SOCIAL HYGIENE ASSOCIATION, AUGUST 15, 1922, ON VENEREAL DISEASE CONTROL.

Figures for industrial policy-holders of the Metropolitan Life Insurance Company during the last four years show a decrease in mortality rates for the venereal diseases. Since 1917 the rate for syphilis locomotor ataxia, and general paralysis of the insane has declined 21 per cent., the figure for 1921 being 13.1 per 100,000, as compared with 16.6 in the earlier year. It is interesting to note that while there was a considerable increase each year from 1911 to 1917, there has been a sharp drop since then. This change is even more significant in view of the fact that reporting is more accurate on death certificates. The decline, therefore, has been accomplished in spite of better reporting. The decline seems to be most decided in the case of syphilis rather than for locomotor ataxia. The figures indicate that the difference between the rates for 1917 and for 1921 is chiefly accounted for by the lowering of the rates in the age period between 25 and 55 years. This improvement may be due to improved methods of treating syphilis as well as to the various measures of control established during the war by private agencies acting in cooperation with the government.

ARSENICAL PREPARATIONS IN THE TREATMENT OF SYPHILIS.

In the *International Journal of Surgery*, Vol. XXV, No. 6, June, 1922, Abr. L. Wolbarst states that a recent investigation made by a committee of German physicians showed that the chance of fatal result

in a properly given injection is about 1 in 13,000 with old salvarsan, 1 in 20,000 with sodium salvarsan, and 1 in 162,800 with neosalvarsan, an average of one fatality in 56,445 injections. Many physicians today believe that in the various refining processes, salvarsan has lost in anti-treponemal potency. On the other hand, some believe that the drug has not lost any of its power, but that the treponema has developed strains that are resistant to arsenic and therefore to arsenophenamin medication. Obviously it is impossible to offer positive proof on either side of this question, but the fact remains that we do not get the results with one injection of arsenophenamin today that a similar dosage effected in 1910 or 1911. Of the six methods of injection, i.e., the intravenous, intramuscular, subcutaneous, oral, rectal, and intraspinal, the intravenous is best for routine therapy. It has been the practice of the author for the last seven or eight years to protect his patients against possible recurrence in such cases by advising a form of "insurance" that has been very satisfactory in his experience. The "insurance" consists of neoarsphenamin injection administered three or four times a year, especially in cases in which there is a fear of neuro-recurrence. The author states that there has not been a single recurrence of any kind in any patient who has taken this "insurance" systematically. In concluding, Dr. Wolbarst reminds us that the two remedies, arsenophenamin and mercury, are powerful poisons and that caution must be taken to consider possible susceptibility or idiosyncrasy.

MALIGNANT NEOPLASMS OF THE EXTRAHEPATIC BILIARY DUCTS.

RENSHAW (*Ann. of Surg.*, Aug., 1922) writes as follows:

Malignancy of the bile ducts, while less common than that of the gall-bladder, is not uncommon. The ratio in a series of 104 cases of malignancy of the biliary ducts and gall-bladder was one to four.

Carcinoma is the most common type of neoplasm found.

Gallstones would seem to be of greater etiologic importance than is generally considered.

Males and females are affected in the ratio of about two to one.

About two-thirds of the cases occur between the ages of 50 and 70 years.

A diagnosis of malignancy of the ducts is uncertain.

After a diagnosis of obstructive jaundice has been made, exploration is generally advisable.

From the standpoint of slowness of growth and rarity of metastasis, surgical treatment should be favorable.

Early treatment of disease of the gall-bladder may occasionally prevent the development of malignancy.

Operation on patients with jaundice carries a high mortality.

[E. H. R.]

THE SURGICAL VALUE OF THE ESTIMATION OF THE BILE PIGMENTATION (ICTERUS INDEX) OF THE BLOOD SERUM.

STETEN (*Ann. of Surg.*, Aug., 1922) concludes that the icterus index determination is of value from the surgical standpoint:

1. As an indicator of the absence or presence of jaundice and as an aid to diagnosis in doubtful cases, being more dependable and delicate than the inspection of the skin and sclera, or the examination of the urine.

2. As a method of accurately estimating, in frank icterus, the pre- or post-operative increase or decrease in the degree of jaundice with the accompanying progression or recession of the disease.

3. As a guide in differential diagnosis, in the placing of operative indications and in prognosis, in cases of outspoken jaundice, by means of the study of the fluctuations in the index figures.

[E. H. R.]

EXTIRPATION OF ONE ADRENAL GLAND FOR THE CURE OF EPILEPSY.

FISCHER (*Ann. of Surg.*, Aug., 1922), basing his operative work on the assumption that the convulsive seizures in epilepsy are the expression of excessive labor performed by the striated muscles of the body, and the fact that in disease or absence of the adrenal gland there is accompanying muscular weakness, has experimentally removed the left adrenal gland in cases of epilepsy, with considerable improvement in some cases. He describes the technic of the operation and reports a number of cases.

EXPERIMENTAL RECONSTRUCTION OF THE ESOPHAGUS WITH AUTOGENOUS FASCIA LATA TRANSPLANTS.

ALLEN (*Ann. of Surg.*, Aug., 1922), from his series of experiments, draws the following conclusions:

1. That it is possible to repair defects in the wall of the cervical esophagus by the use of autogenous fascia lata transplants.

2. That the stratified epithelium lining the esophagus in the dog possesses the power of regeneration to a degree sufficient to enable it to bridge over defects which have been filled in with fascia lata transplants.

3. That infection along the cervical portion of the esophagus may produce a mediastinitis or a mediastinitis associated with a general empyema.

4. That this infection is accompanied by leakage of the contents of the esophagus.

5. That silk or linen should not be used for suturing the mucosa.

6. That stenosis may or may not be found after repair of defects in the wall of the esophagus with fascia lata transplants.

[E. H. R.]

PERFORATION OF DUODENAL ULCER FOLLOWING GASTRO-ENTEROSTOMY.

DOUGLAS (*Ann. of Surg.*, Aug., 1922) reports a case in which this accident happened, and finds after a careful search of the literature that the total number of cases so far reported is only 29. He speaks briefly of the type of cases in which this thing occurs and reports by means of a schematic chart the results in all of the cases found in the literature.

[E. H. R.]

LYMPHOSARCOMA OF THE INTESTINE.

DENOYELLES (*Ann. of Surg.*, Aug., 1922) summarizes his paper as follows:

1. Two cases of lymphosarcoma of the intestine are described, one of tumor of the jejunum, the other of the ileum. In one instance the tumor was a diffuse infiltration of the intestinal wall, an amular type of growth. In the other case a lymphosarcomatous polyp was found which gave rise to an intussusception.

2. The microscopic picture leaves much speculation as to the origin of the tumor cell, but in these two cases the predominant cell is one which resembles a great deal the transitional large mononuclear cell of the blood.

3. Lymphosarcoma of the intestinal tract is difficult of clinical diagnosis, the signs being simply those of malignancy, with partial obstruction being rather constantly present. X-ray examination was of no help in these two cases.

4. Treatment consists of radical removal of the

primary growth with as much of the metastases as is possible. Improved methods of radium application might be a valuable therapeutic adjunct.

5. Chronic irritation, possibly a specific toxin, may play an important rôle in the genesis of lymphosarcoma. The histology of infectious granulomata of the intestine often simulates this tumor. Perhaps lymphosarcoma is only one of the many bizarre late pictures of lesions which were at one time of the nature of Hodgkin's disease or lymphoblastic or lymphocytic leukemia.

[E. H. R.]

PRIMARY TUMORS OF THE URETHRA.

SCHOLL and BRAASCH (*Ann. of Surg.*, Aug., 1922) write as follows:

Malignant tumors of the male urethra often develop following long-standing urethral infections. Primary tumors are extremely rare both in the male and female. In the female they are generally located in the anterior urethra and tend to grow outward, away from the bladder.

Most malignant tumors of the urethra are squamous-cell growths. They are highly malignant, but are well walled off by fibrous tissue and lymphocytic infiltrations. They tend to remain limited to the local condition and to the regional lymph glands, and usually respond readily to radium treatment.

Three cases of epithelioma of the female urethra and one of the male urethra are reported from the Mayo Clinic.

Benign solid tumors are only rarely seen in the urethra. The majority of these belong to the group of fibromyomas. One case of fibroma of the female urethra is reported.

[E. H. R.]

PLASTIC SURGERY OF THE FACE, INCLUDING TREATMENT OF COMPLETE DOUBLE HARELIP.

HIGHSMITH and VEAU (*Ann. of Surg.*, Aug., 1922) present two very valuable articles on this subject, profusely illustrated with excellent drawings showing technic. VEAU's drawings are of especial interest and value. These two articles form a valuable symposium on this subject.

[E. H. R.]

RESULTS OF TREATMENT IN FORTY-EIGHT CASES OF SCIATICA.

OTT (*Ann. of Surg.*, Aug., 1922) states that in 48 cases of sciatica in which no definite causative factor could be found, repeated epidural injections, combined with the removal of possible foci of infection in a large percentage, resulted in permanent cure in 29 per cent., and permanent amelioration of symptoms so that the patient was able to continue his occupation with a fair degree of comfort in 37 per cent.; in the remaining 21 per cent. no permanent beneficial results were obtained.

[E. H. R.]

GLUCOSE TOLERANCE AND ITS VALUE IN DIAGNOSIS.

LOUIS (*Ann. Metabolic Research*, 1, 497, April, 1922; actually received July 29) presents 20 tables and 111 charts and a text discussion sufficiently condensed and crisp to be good reading. The most stimulating statements are these:

Following the forced fluid intake of the test (about a quart in about four hours), urine volume was smaller than the intake in about 50 per cent. of the non-diabetics, but in as many as 75 per cent. of the diabetics. His probable explanation was that the persistent hyperglycemia "holds" the water.

The time of the maximal blood sugar was in 49 per cent. of the diabetics at two hours, and at one

hour in 33 per cent.; whereas it was at the half-hour in 51 per cent. of the non-diabetics, and at one hour in 37 per cent.

"The more peak . . . appears to have little or no significance. The most important point is the length of time which it takes for the reestablishment of the normal level. After the ingestion of 100 gm. glucose, if the curve comes back to normal inside of three hours, the individual is considered non-diabetic." (Much the same contention has been made by Hamman, but so far without winning attention from the peak.)

Glycosuria and hyperglycemia are independent. In 715 observations 11 per cent. showed glycosuria despite normal glycemia, while in 18 per cent. glycosuria was not manifested in the presence of hyperglycemia. "Thus the percentage of error in diagnosis when a urine examination alone is made may be 32 per cent."

"There is no such thing as a fixed normal renal threshold, usually placed at 170 mg. per 100 c.c." (In connection with this statement one should not overlook Folin and Berglund's recent evidence in support of the renal threshold.)

[H. G.]

AN IMPROVED ALIMENTARY GLUCOSE TOLERANCE TEST.

BEELER, BRYAN, CATHCART and FITZ (*Jour. Metabolic Research*, 1, 549, April, 1922) propose "a simple modification" of the well-known 100 g. glucose tolerance test. One hour after ingestion, the stomach was emptied with a Rehfuss tube, the percentage of sugar recovered was titrated and also the blood hemoglobin was determined. With these figures two corrections were made of the blood sugar values. (This study seems, even to a believer in the utility of more mathematics in medicine, rather profound and stimulating than convincing. In the forest of figures one seems to lose sight of the evidence in the literature that in a given individual much the same glycaemic curve is obtained, whether the dose of glucose be 20 grams or 200, i.e., the amount absorbed in surprisingly immaterial. From table 3 one sees that the fraction of glucose recovered from the stomach varied in 21 cases from a trace to 63 per cent. Or one can derive the average of 31 per cent., that is, the average subject absorbed 69 g. glucose. Only two cases absorbed less than 22 g., hence only in these should the reviewer expect the new technique to be helpful. Despite these reservations, the method merits attention, since the accuracy aimed at, and claimed, will when confirmed be a most valuable asset.)

[H. G.]

CLINICAL OBSERVATIONS ON TREATMENT AND PROGRESS IN DIABETES.

FREDERICK M. ALLEN and JAMES W. SHERRILL (*Jour. Metab. Research*, March, 1922, 1, page 377) write:

"This paper is an exhaustive statistical analysis, the first to come from this clinic, from which most of the material so far has been in the nature of studies on individual animals and men. The article is too long to do more than pick out certain points. The authors offer a plan which they suggest may be adopted by others for the sake of comparison. The principle of general agreement on a method of statistics is certainly important, while many of the arguments detailed by these writers differ from their predecessors.

They say that patients coming to obtain advice on a single occasion are ordinarily not taken under treatment by the consultant, nor does he undertake responsibility for the future, such cases, these authors exclude. It may be interesting to compare with this review the recent statement by Joslin: "Statistics based on selected series cases are plausible but unsat-

isfactory. Though a diabetic patient is seen but once, an influence should be exerted to guard that patient from coma or gangrene, and to state all those possible legitimate hopes and prospects by which the patient's courage may be and often is maintained." Furthermore, the reviewer would urge that an expert's advice on a single occasion may well be worth more to the patient than uninformed advice on many occasions.

They assert: "With an insignificant number of exceptions these patients had mild diabetes, as is likely to be the case with those who request merely an incidental opinion. There is a reasonable expectation that all but a very few of them are alive, and the inclusion of this group would certainly make the general statistics appear much more favorable." The reviewer ventures the protests that mild diabetes very often becomes severe and also that assumptions as to the viability of untraced cases often prove later, after the cases have been traced, to have been surprisingly mistaken.

"Any deaths that occur shortly after consultation on account of complications then existing have been included in the following tables." (Agreed.)

"The physician is called to see whether patients . . . with dangerous complications such as coma or infections already present. As these complications have not developed under the diabetic treatment, they are not a test of the treatment of diabetes as such." (Omission of patients in actual coma, i.e., unconscious, seems to the reviewer legitimate. But patients with infections should, some of us believe, not be excluded, in view of both the great variability of the severity of the infection when first seen, and also the good outcome in some diabetics with even severe carbuncles or gangrene.)

Allen and Sherrill most justly observe that "some former opinions of the unreliability of diabetics are untrue for the majority will follow diet conscientiously," when properly instructed. (At the same time, regarding their exclusion of patients who are considered unfaithful to treatment, it seems important to remember the difficulty of estimating the exact amount of foods eaten, the tendency of most patients, after they go home, to estimate rather than weigh their food, and the resulting lapses, as evidenced by the frequency with which patients return and are found on careful observation to be no more severe than previously; that is, they became sugar free when put on their same old diet, actually measured instead of guessed. Therefore, it seems to us that patients should not be excluded on this ground of infidelity to treatment, although it certainly is most instructive to examine the separate tabulations by these authors).

Finally, their critiques of the work of Petten and of Newburgh and Marsh deserve attentive reading.

[H. G.]

INTESTINAL ADENOMAS OF ENDOMETRIAL TYPE. THEIR IMPORTANCE AND THEIR RELATION TO OVARIAN HEMATOMAS OF ENDOMETRIAL TYPE (PERFORATING HEMORRHAGIC CYSTS OF THE OVARY).

SAMPSON, J. A. (*Archives of Surgery*, Sept., 1922) presents a 73-page article on this subject profusely illustrated with excellent drawings explaining the text, and draws the following conclusions:

Intestinal adenomas of endometrial type are implantation growths, similar in many ways to those arising from a rupture or perforation of a malignant (carcinomatous) ovarian cyst. Fortunately, their distribution is usually not so great; they are not so invasive; they grow more slowly and spread less rapidly. They often take part in menstruation and, therefore, may combine this function with that of invasion. These implantations may spread by growth, by continuity and, possibly, by further implantations arising from the escape of menstrual blood from them, carrying some of the overlying epithelium with it.

The portions of the intestinal tract most frequently involved are those usually found in the pelvis; as the sigmoid, rectum, appendix and terminal loop of the ileum. In the twelve cases reported in this series, the rectum and the sigmoid, including the epiploic appendages, and the mesentery of the latter were involved in eight, the appendix in four, and the small intestine in two. In the eight instances of implantations on the sigmoid and rectum, an ovarian hematoma, with evidence of a previous perforation, was situated in the left ovary in six; while in the four instances of implantation on the appendix, a similar hematoma was situated in the right ovary in all four. This suggests that while the intestinal implantations from either ovary may be general in their pelvic distribution, the portion of the intestinal tract normally situated near the ovary is more likely to be involved.

The character of the intestinal lesions varies greatly, and they may be grouped as follows:

1. Surface and superficial implantations;

2. Implantations developing between adherent folds of peritoneum and other adherent structures (pocketed implantations), best seen in the cul-de-sac between the posterior wall of the uterus and the rectum, which are often fused together. The surface of the adherent parts, which are exposed after separating them, often have a characteristic "pitted" appearance due to the exposure of endometrial tissue in the pockets between the adhesions or in the deeper tissues of the organ involved.

3. The deep invasion of the underlying structure or organ: The tubules worm their way into the tissues of the intestine; and this is often associated with a marked hypertrophy of the surrounding connective tissue and muscle. Many varieties of endometrial tissue and its derivatives may be found, including glands and tubules with and without a characteristic endometrial stroma, dilated tubules, miniature uterine cavities, hematomas and the invasion of lymph vessels by endometrial polyps.

As an implantation carcinoma these implantations may occur on any part of the intestine; its peritoneal surface, its mesentery and especially the epiploic appendages of the sigmoid. The latter may serve as a portal of entry to the deeper tissues of the wall of the intestine.

The intestinal lesions are often only of histologic interest and do not give rise to any symptoms. In other cases the lumen of the intestine is encroached upon by indentations, by hypertrophy of its walls, and by hematomas; the latter may become larger during menstruation so that symptoms of obstruction may only occur or be more marked at that time.

The operative treatment of intestinal adenoma of endometrial type is at present an unsettled problem. My own reaction, at present, on finding what appears to be an intestinal lesion is to examine carefully the surface of the intestine for dots and areas due to hemorrhage, to look for other implantations in the pelvis, and most important of all to examine carefully the ovaries for any sign of a hematoma with evidence of a previous perforation, bearing in mind that it may be very small and is most frequently situated on the lateral or the under surface of the ovary. If the evidence found indicates an adenoma of endometrial type I do not disturb the intestinal lesion, except as it may be easily removed for histologic study, but deal with the pelvic organs as their condition requires. Conservative ovarian surgery in these cases leaves behind a possible source of more implantations, and apparently retained ovarian tissue may sometimes stimulate the growth of the implantations which have not been removed.

Intestinal adenoma of endometrial type is a common condition occurring in more than one half of the cases with ectopic endometrial adenomas and the latter may be found in from 10 to 20 per cent. of women between 30 years of age and the menopause, who require an abdominal operation for some disease

of the pelvic organs. On account of its frequency, pathologic interest and clinical importance, it deserves a greater recognition than has been accorded it in the past.

[E. H. R.]

THE AUTOTRANSPLANTATION OF ENDOMETRIAL TISSUE IN THE RABBIT.

JACOBSON, V. C. (*Archives of Surgery*, Sept., 1922) writes as follows:

It has been demonstrated in this series of experiments that endometrial tissue transplanted into the ovary and pelvic fat of the same animal will grow for as long as seventy days and probably much longer. Adenoma-like growths and multilocular cysts, which, histologically, show much similarity to "ovarian" cysts-adenomas of women, are produced. Under the influence of pregnancy, a more rapid epithelial growth occurs, with the production of a papillary "cyst-adenoma" which has some of the characteristics of a malignant growth. All of these observations are in agreement with Sampson's explanation of adenomas of the endometrial type which are found in the ovary, in the cul-de-sac, adherent to and invading the appendix, intestine, rectum, oviduct and uterus, and which apparently arise from ectopic epithelium discharged into the pelvis through the fimbriated end of the oviduct, this epithelium coming either from the uterus or the oviduct or from both.

[E. H. R.]

PREOPERATIVE TREATMENT OF MALIGNANT TUMORS OF THE BLADDER BY RADIUM.

SCHOLL, A. J., and BRAASCH, W. F. (*Archives of Surgery*, Sept., 1922).—These authors write as follows:

Radium rays administered in small amounts definitely destroy the proliferative power of living cells. The activity of the cell is lessened, and it passes through a quiescent stage from which it gradually recovers as the effects of the radium wear off. In many cases, there is destruction of the nuclei which is accompanied by an atypical cell growth and vascularization, and later by fibrosis.

At the Mayo Clinic, the flat, infiltrating, rapidly recurring type of bladder tumor is exposed to radium before operation in an effort to reduce the activity of the malignant cells and prevent operative transplants and early postoperative recurrences. Tubes of radium emanation are inserted through the direct cystoscope into the substance of the tumor, which later is removed surgically. Specimens for histologic study are removed from the tumor before irradiation, and their histologic structure is later compared with that of the surgically removed area. In the majority of cases, there is a marked reduction in the size of the tumor, with a widespread and constricting fibrosis.

[E. H. R.]

PRIMARY SQUAMOUS-CELL CARCINOMA OF THE KIDNEY AS A SEQUEL OF RENAL CALCULI.

WELLS, H. G. (*Archives of Surgery*, Sept., 1922) writes as follows:

The formation of keratinizing squamous-cell carcinoma in the renal pelvis is a rare occurrence. In the case reported, which is of this sort, the metaplasia of the transitional epithelium to the squamous form was apparently the result of chronic irritation from renal concretions.

[E. H. R.]

URETHROSCOPIC FINDINGS IN FUNCTIONAL DISORDERS OF THE GENITO-URINARY TRACT.

WOLBARST, A. L. (*Journal of Urology*, March, 1922) writes:

Fifty consecutive cases were selected, having well-defined clinical symptoms, which can be placed in one of the three groups just mentioned.

The conclusions drawn are:

1. Functional disturbances of the genito-urinary tract are invariably associated with pathologic lesions in the posterior urethra.

2. These lesions usually involve both the verumontanum and the urethral canal behind it, occasionally also the internal sphincter.

3. When the urine is hyperacid, urinary frequency is likely to be the predominating symptom.

4. In 64% of cases, in this series, there was no history of previous gonococcal infection.

5. Excessive masturbation, prolonged sexual excitement without gratification, and withdrawal (coitus interruptus) practiced for long periods seem to be the etiologic factors in the nongonorrheal cases.

6. Whatever the etiologic factor may be, the resulting functional disturbance does not follow any specified type; and there is no apparent correlation between the clinical phenomena and the urethroscopic picture.

7. Sexual neurasthenia, so called, is a misnomer; it should be considered an aggregation of more or less serious disorders involving one or more functions of the genito-urinary tract and associated with definite pathologic lesions in the prostate and seminal vesicles and reflected in the urethroscopic picture of the verumontanum and posterior urethra.

8. Every case of functional disorder referable to the genito-urinary tract should be subjected to thorough study and examination through the urethroscope. [B. D. W.]

THE USE OF THE HIGH FREQUENCY CURRENT IN THE TREATMENT OF LESIONS OF THE DEEP URETHRA.

YOUNG, H. McCLURE (*Journal of Urology*, March, 1922), writes:

The lesions of the urethra posterior to the cut-off muscle are:

1. An inflammatory overgrowth of the mucous membrane which may take the form, (a) of a generalized hypertrophy of the mucosa throwing it into rather coarse folds and rugae, or (b) the more localized hypertrophies known as polyps. Often both conditions are present.

2. Granular areas, fairly well localized but not sharply outlined as a rule. In long-standing cases these may have undergone a rather exuberant proliferation, giving rise to a sort of tumor, a granuloma. Papillomata are very uncommon in the deep urethra.

3. Small sinuses running out of the deep urethra into the substance of the prostate are very common, and should always be carefully looked for. These can be lightly cauterized with a Bugbee fulgurating electrode.

Varicose veins sometimes occur in the deep urethra.

These lesions can be controlled by high frequency current applied with great accuracy under control of the eye.

The paper concludes with a method of fulgurating offending prostatic lobes. [B. D. W.]

TYPES OF NEPHRITIS WHICH LEAD TO UREMIA.

FOSTER, NELLS B. (*Journal of Urology*, March, 1922), writes:

Confining ourselves strictly to facts, we have evidence at present only that uremia in any of its forms is a result of impaired renal function; this medium of evidence is always procurable. Furthermore, that the degree of impairment is directly proportionate to the number of renal elements (tubule and glomerulus) that are damaged seems quite probable, although not established. We should find then the solution to our query concerning the uremia producing type of nephritis not in a type, but rather in a degree

of severity, not a qualitative, but a quantitative relation. [B. D. W.]

FOREIGN BODIES IN THE BLADDER.

DAY, R. V. (*Journal of Urology*, March, 1922), writes:

A summary of the various methods of removing foreign bodies from the male bladder. The variety of foreign bodies found is,—chewing gum, paraffin, broken-off pencils, small irrigating nozzle, hairpins, and hatpins; any of the above may be more or less encrusted with urinary salts, depending on the length of time they have been in the bladder.

A small lithotrite, where the female blade has no fenestrum, but is cupped and so blunt that no injury is done to the bladder mucosa, is very satisfactory.

Employment of cystoscopic forceps through the operating cystoscope may be successful.

An oval-shaped stone was removed by the author, using a large-sized Braasch cystoscope, No. 25 Chariere. Through the catheter guide in the cystoscope was introduced an alligator forceps. [B. D. W.]

ATROPHIC PYELONEPHRITIS.

BRAASCH, W. F. (*Journal of Urology*, April, 1922), writes:

Pyelonephritis is, as a rule, not regarded as a surgical disease of the kidney for two reasons: (1) acute infections usually resolve spontaneously, and (2) chronic infections are almost always bilateral and respond in greater or lesser degree to medical treatment. Unilateral pyelonephritis, which does not respond to medical treatment, becomes a surgical condition and usually demands nephrectomy.

Atrophic pyelonephritis is distinguishable from chronic bilateral pyelonephritis; in the former the urinary symptoms are less severe and are usually not progressive; the pain is unilateral and may be more severe and is frequently accompanied by evidences of acute renal infection.

Atrophic in contrast to bilateral pyelonephritis, the bladder is usually found on cystoscopy to be involved only to a moderate extent or not at all. The phenolsulphonphthalein test is of great clinical significance as it usually is markedly diminished on affected side and the other side will usually show increase. In bilateral the function is usually diminished on both sides.

The differential is pelvic reduplication—wide stricture of the lower ureter, chronic renal tuberculosis.

The etiology is probably a primary aseptic infarct. Operation gives relief. In the 28 cases reported in this paper all but one was markedly relieved. [B. D. W.]

CONCERNING THE EFFECT OF SALINE PURGATIVES ON THE ABSORPTION AND EXCRETION OF PHENOLSULPHONPHTHALEIN.

MACHT, DAVID I. (*Journal of Urology*, April, 1922), writes:

In experiments on dogs the output of phenolsulphonphthalein is decreased by one-half, when a solution of sodium sulphate or a magnesium sulphate is administered at time of giving drug. The same experiment was repeated, but the dye was given intramuscularly rather than orally, and again the output was markedly retarded. Tests were then made on loops of intestines, jejunum, and the results showed the loop containing the saline purgative retained much greater quantity of dye.

The author then tried salines on himself and some colleagues and all showed retarded output when taking salines. It appears probable that osmotic phenomena and an increased concentration of the blood play the principal part.

The tests on man are few, and further experiments must be carried out as this is only a preliminary report. [B. D. W.]

THE BOSTON Medical and Surgical Journal

Established in 1828

Published by The Massachusetts Medical Society under the jurisdiction of the following-named committee:

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

THE STUDY OF MATERNAL MORTALITY.

THE committee appointed for the purpose of studying the factors involved in maternal and infant mortality has been at work analyzing the returns filed at the State House. A questionnaire has been sent to every physician whose name appears on the death certificate, asking for information relating to the antenatal conditions and the circumstances attending maternal deaths.

It is gratifying to find that a large proportion of the physicians appealed to have shown a spirit of coöperation for which the societies represented on the committee should be thankful. There are, however, some who have not taken the trouble to reply and the committee would call the attention of the profession to the importance of this study and the obligation which the profession of medicine imposes on its members to add to the common knowledge relating to the causes of death under investigation.

This study has not been prosecuted with the purpose of finding opportunities for criticising any practitioner, but rather to ascertain the reason for these casualties, if possible. Several eminent men have interpreted the facts as indicating lack of understanding of the basic principles of hygiene by the laity and failure to secure early medical supervision and assistance; others have felt that the practice of midwives

has contributed to disasters in some localities, while still others suspect that meddling midwifery and resort to uncalculated-for operations may have some influence.

It is generally conceded that the practice of obstetrics by well trained and judicious accoucheurs is securing better results than ever before in the history of medicine and since state registration is gradually eliminating the less well qualified doctors, the average service should be better. Some published statistics seem to indicate that we have passed the peak of relative mortality and there is hope that future records will demonstrate this expected improvement.

There is, however, a logical contention that the conditions of modern life do not, in some instances, fit women for the responsibilities of maternity and that because of impaired vitality there may be less resistance to sepsis and greater danger of toxemia among parturient and pregnant women.

It has been contended that the development of surgical technique and aseptic precautions have led to an undue dependence on some operative procedures. This may be an open question and call for some authoritative opinion, and although it is too early to speak definitely on this phase of obstetric practice, the rule adopted by some hospitals in requiring competent consultation before resort to major operations in obstetric cases, seems to indicate that the fear exists in some minds that enthusiastic operators need some restraining supervision.

These are all matters of concern to the medical profession and in order to arrive at logical conclusions, physicians should contribute the facts under observation. The Committee of the Massachusetts Medical Society and the Massachusetts Homeopathic Medical Society, respectfully solicits the assistance of physicians in this state, in the study now being made.

THE PRACTICE OF MEDICINE BY THE CLERGY.

ACCORDING to Dr. Egbert H. Grandin of New York, a movement has been inaugurated for the purpose of legalizing an alleged method of curing disease by the laying on of hands according to the methods employed by Mr. Hickson.

The champion of this movement is the Bishop of New York. He is reported to have given Mr. Hickson every opportunity to demonstrate his methods when he, the Bishop, was Rector of Trinity Church. If this report is true it is time for the medical profession to put aside its conservative attitude and take the field in a campaign of opposition to any plan which seeks to deceive the people. Physicians have been reluctant to enter upon any controversy involving the application of religious faith in the cure of disease through mysticism, for physicians as a class share with the great majority of mankind

a profound respect for true religion and so far as religious teaching and practice are applied to the spiritual and moral nature, extend encouragement and support. But the profession as a body understanding the behavior of those diseases which have a recognized pathology, would resent the impious assumption that the operation of natural laws can be suspended by methods which appeal to the emotions rather than to reason. If it could be shown that the Deity is disposed to suspend the known laws of disease, physicians would forsake their arduous tasks and enter the orders of the Church, but experience has demonstrated that certain diseases are inexorable and do not respond in any great degree to the mental or moral attitude of the sufferer. It is, of course, generally conceded that functional conditions can be materially modified or a cure effected through changing the mental attitude. If this phase of treatment is recognized and given its proper application, the psychic effects of good counsel and the encouragement extended by a dominating personality have their proper places.

Some years ago, the movement in Boston which had for its objective the bettering of physical and mental disorders logically employed medicine as its coadjutor and whenever it was found that an organic disease was suspected a physician's advice was sought. This latter movement was misinterpreted and criticised. It did not seem to accomplish all that was expected of it by its supporters, although the motives were good and the practice free from unsound methods.

It is still in operation and is endorsed by physicians and patients. It is respectfully suggested that Dr. Grandin is in error in placing this local effort in the same class with the plan advocated by the Bishop of New York.

In distinction to the Boston movement many theories and practices relating to morbid condition which have been exploited from time to time, unless founded on scientific knowledge and applied by competent physicians have been abandoned. The hectic flush of over-enthusiasm has too often preceded dissolution.

The clergy will hold their position of influence so long as they deal with the problems of ethics and religion, but diseased minds, as well as bodies, must in the end be presided over by painstaking and competent physicians. The people must beware of false teachers, even though they are in high places.

PLOTTING DEATH RATES.

In the Public Health Reports for August 18, 1922, Professor George C. Whipple and Miss A. D. Hamblen present arguments for the use of semi-logarithmic charts for plotting death rates. The vertical scale is based on the logarithms of the numbers from 1 to 10, with subdivisions, and these repeat themselves, the dis-

tances between 1 and 10, 10 and 100, and so on, being equal, the horizontal scale is arithmetical, and therefore uniform. This plan is especially useful for long-time records, and the significance is more easily appreciated than when curves are shown on cross-section paper. Several illustrations are given, the interesting facts being that from 1851 to about 1890 the death rate in Massachusetts rose slowly from 18 to nearly 20 per 1000, then it began to go down, with some variations, until 1921, when it reached 12 per 1000.

The reason given for the change beginning with 1890 is the application of the science of bacteriology, for it was the employment of this science in water purification, sewage disposal, and the development and distribution of diphtheria antitoxin, and allied efforts, supplemented in about 1910 by pasteurization of milk, and other health measures, which may be regarded as the most important factor. Speaking of tuberculosis, the statement is made that "one may almost venture to predict its future death rate," for if the present decline continues, the death rate for this disease will be 38 in 1950, as compared with the present rate of 82 per 100,000.

Typhoid fever, diphtheria, scarlet fever, and infant mortality show an encouraging diminution. In contrast, the analyses show that the death rates from Bright's disease, cancer and organic heart diseases are steadily increasing. The mortality from measles and whooping cough has not diminished.

Several other matters of interest warrant careful study by persons interested in statistics. Such analytical presentations convey encouragement in some directions, and furnish incentives for study of those diseases that are baffling.

EDITORIAL NOTE.

In another column of this number of the JOURNAL appears the Program of Meetings of the Suffolk District Medical Society for 1922-23.

There will be an opportunity to hear some of the foremost medical men in this country. The subjects of the meetings are quite different from the subjects usually presented. Every member of Suffolk District owes it to himself, as well as to the Society, to attend as many of these meetings as possible.

NEWS ITEMS.

ANNOUNCEMENT OF DR. CHRISTIAN.—Dr. Henry A. Christian begs leave to announce that, having arranged to curtail the time devoted by him to teaching work in the Harvard Medical School, he will resume consultation work in internal medicine on October 1, 1922. Patients will be seen also by appointment in his office at

the Peter Bent Brigham Hospital, corner of Huntington Avenue and Francis Street, Boston. Patients requiring special study can be admitted to the Peter Bent Brigham Hospital for observation. Dr. Cyrus C. Sturgis will be associated in this work.

WEEK'S DEATH RATE IN BOSTON.—During the week ending Sept. 9, 1922, the number of deaths reported was 166, against 161 last year, with a rate of 11.3 against 11.08 last year. There were 33 deaths under one year of age, against 26 last year.

The number of cases of principal reportable diseases were: Diphtheria, 38; scarlet fever, 9; measles, 8; whooping cough, 48; typhoid fever, 3; tuberculosis, 27.

Included in the above were the following cases of non-residents: diphtheria, 5; scarlet fever, 2; tuberculosis, 7.

Total deaths from these diseases were: diphtheria, 4; whooping cough, 2; tuberculosis, 12.

Included in the above were the following cases of non-residents: diphtheria, 1; whooping cough, 1; tuberculosis, 2.

EASTERN HAMPTON MEDICAL ASSOCIATION.—The Association will hold its monthly meeting at the Springfield Academy of Medicine, October 5. Theme: "Spinal Puneture." Speakers: Drs. M. B. Hodskins, I. N. Kilburn, S. D. Davis, J. M. Birnie, and H. S. Cleveland.

BEVERLY HOSPITAL CLINIC.—Following is the program of the monthly clinic held at the Beverly Hospital on Tuesday, Sept. 19th, at 4 p. m.:

Specimens of extrauterine pregnancies.

Pancreatitis.

Appendicitis, acute.

Tumor of the lower abdomen, lipoma, retroperitoneal—weight 10 lbs.

Tumor of abdomen (in child): pre-operative diagnosis—retroperitoneal sarcoma.

Diabetic gangrene.

Intestinal obstruction.

Carcinoma of sigmoid.

Fracture of skull.

Fracture of skull.

Fracture of skull.

Fracture of skull.

Traumatic cerebral hemorrhage.

Miscellany.

WORCESTER DISTRICT MEDICAL SOCIETY.

The first regular meeting of the Worcester District Medical Society was held in the rooms

of the University Club, Worcester, September 13, at 8.15 P. M.

Dr. Geo. M. Albee read a paper on Classifying Our Cardiacs, a synopsis of which may be found below. The paper was discussed at length by Dr. A. S. Levine of Peter Bent Brigham Hospital, Boston, and by Drs. Stevens, Curran, Hurd, and others.

At the business meeting a committee was appointed consisting of Drs. Shannahan, R. J. Ward, Ellison, Hurd, and McKay, to consider the question of the adoption by the Society of the A. M. A. Caduceus for the members automobiles in place of the green cross now used so extensively by many cults.

It was voted to accept the invitation of the Worcester North District Society and meet with them in October, the date to be arranged later.

CLASSIFYING OUR CARDIACS.

PATIENTS who come to us complaining of shortness of breath, swelling of the legs, precordial pain, palpitation, cough after exertion, dizziness, fainting or weak spells, may be placed in two groups, functional and organic heart disease.

The functional cases, which are by far the more common, may be divided into five groups, (1) Constitutionally Inferior, (2) Emotionally Sensitive, (3) Neurotics, (4) Neurological Basis, (5) Physical Strain, and I think we could add the Tachycardia of Hyperthyroidism to these groups.

1. The constitutionally inferior complain of faintness, dizziness, shortness of breath and palpitation. The majority of them are young adults or adolescents. They are rather sickly looking with thin undernourished bodies, blue cold hands, rapid pounding hearts with a systolic thrill at the apex and with sweat running down from the axillae. They say they have been nervous and tired since childhood, or they have been told they have heart disease. They never hunted or fished or played football or hockey and they never knocked a home run. They left school at an early age and a low grade. Their first job was too hard. They kept getting easier ones. They are bell boys, or timekeepers, or chauffeurs, or they run elevators. Their family history is poor. Parents died young, or are not very well. On physical examination we may find a systolic murmur at the apex. It varies with the phase of respiration. There is no enlargement of the heart and there is no history of rheumatic fever. The heart rate will slow up on stooping. There may be an impure first sound at the apex suggestive of a presystolic murmur, but it will clear up on inhaling a pearl of amyl nitrite.

2. The emotionally sensitive are healthier looking. Their past history is better, but they are easily upset and they break down under severe mental strain. They complain of shortness of breath and weak spells. In the Army they became the cases of shell shock. Their physical findings are about the same as the con-

stitutionally inferior. They improve under a change of surroundings and rest.

3. The neurotics complain of faintness. They vomit without cause, have hysterical attacks. They have long barrel-shaped chests. These cases are often taken for hyperthyroidism. They have the four cardinal symptoms—tachycardia, tremors, loss of weight, and struma. The only proof is the indefinite history of onset and basal metabolism; though these cases have no pep and the goiter cases are full of energy. The physical findings in the heart are negative.

4. Those with a neurological base have a history of epilepsy, basal meningitis, encephalitis, or damage to the nervous system during infection.

5. Physical strain. After an illness one is weak. The skeletal muscles tire easily. One gets short of breath doing what he used to do without knowing he had a heart. In health the skeletal muscles will give out before the heart does.

Hyperthyroidism might be spoken of here, as in its early stage the heart change is a functional one, though later in life there is a myocardial change and the patient comes under the group of organic hearts, or goiter heart which is a branch of the sclerotic hearts.

Patients with organic heart disease may be divided into two groups, the infectious and the degenerative or sclerotic.

They may also be divided into two groups, the active and the inactive. That is those where the damage is being done and those where the heart structure has been damaged at some previous time. These should really be called affected hearts rather than infected. We have had the infection, now we have the affection. The scar tissue is what is interfering with the work of the heart, and we are called upon to treat the patient for heart failure rather than for heart disease.

It is easier to handle our heart cases if, as Dr. White suggests, we study them from three standpoints,—etiology, structural change and functional condition. If we group them as I have suggested, we have considered the etiology and it is wonderful how that clears up a case. Has the patient any reason for having heart disease? If he has a reason, if he has had rheumatic fever, has it produced any structural change? If it has affected the endocardium there will be a change in the heart sounds. There will be a murmur. If there is a diastolic murmur heard at the left border of the sternum, or at the base, or at the apex, even though the murmur is heard only at the end of a forced expiration he has an aortic insufficiency and the prognosis is not good. If he has a presystolic murmur and a failure of the congested type or auricular fibrillation, he has mitral stenosis and the prognosis is poor. If he has a systolic murmur at the apex and an enlarged heart and a history of infection, he has mitral insufficiency and the prognosis may not be very bad, as these cases respond to rest and

digitalis. If he will limit his activities and not use up his cardiac reserve, he can live much longer than the patient with mitral stenosis or aortic regurgitation. We have to remember in giving our prognosis that our diagnosis of mitral disease is not always confirmed by autopsy.

Pericarditis is common, if watched for. It is found most often by the medical student and the interne and the pathologist. It is easy to overlook as the friction rub may be present for only a short time, perhaps an hour or two, and the effusion may be very slight, not enough to cause mechanical embarrassment. Perhaps it is just as well for the patient that pericarditis is not discovered oftener, because when there is fluid, there is a temptation to aspirate, and generally the effusion will take care of itself. Pericarditis may occur in the course of rheumatic fever, generally following endocarditis, as shown by friction rub, or indistinct heart sounds, or increase in cardiac dullness, or it may occur as a terminal thing, as shown by the pathologist.

There may be structural change in the myocardium, chronic myocarditis, as shown by weak or impure sounds, by limited field of activity, or by failure of the anginal or congestive type, or by irregularities.

It is always quite worth our time to look for the cause of precordial pain, especially if it follows exercise. We should note the character and distribution of the pain, and the action of the patient during the pain, and the effect of nitroglycerine. It is common to have pain in the left chest due to muscular strain or infected teeth. These are more apt to occur in young adults. After middle life it is safer to get an electrocardiogram of any patient who complains of pain around the heart, and it is safer to give a guarded prognosis.

The irregularities are divided by Lewis into seven classes,—sinus arrhythmia, heart block partial or complete, premature beats, paroxysmal tachycardia, auricular flutter, auricular fibrillation and pulsus alternans.

In sinus arrhythmia the impulse arises in the s-a-node at irregular intervals. The auricular and ventricular complexes are normal but the rate is irregular. It is of no clinical significance. At times it is impossible to diagnose sinus arrhythmia without the electrocardiogram.

In heart block there is a defective conduction of the impulse from the auricle to the ventricle. It may be a delayed conduction or it may be cut off entirely. The three common causes of heart block are sclerosis, inflammation, and digitalis. The electrocardiogram is a great help in differentiating heart block from premature beats, and from bradycardia and from a slow auricular fibrillation.

In paroxysmal tachycardia the impulse arises in the annular wall node at an abnormally high rate. The attacks begin and end abruptly. The main point in diagnosing paroxysmal tachycardia is that the rate does not change from minute to minute or with exertion or change of

position. As Dr. Levine has shown, the rate should not vary more than two beats per minute. That allows for the error in counting. There is no treatment except pressure on the vagus. The patient may stop the attack himself by holding the breath, stooping or vomiting.

Auricular flutter is a condition in which the auricle beats regularly at a very rapid rate, from 200 to 321 a minute. It is practically impossible to detect flutter without the electrocardiogram. We may suspect it when a patient with a moderately rapid pulse has symptoms that are too severe for our clinical findings. If we give digitalis in large doses till we get a slower rate and fibrillation, and then withdraw it and get a normal rhythm we may be quite sure that we had flutter.

In auricular fibrillation some part of the auricle is constantly contracting, but the movement as a whole is more or less incoördinate. The pulse is totally irregular. If the rate is over 100 there are some beats that do not go through to the radial and we have a pulse deficit. If the rate is increased by exercise or fever the irregularity decreases with increase of rate. The prognosis depends on the rate at which we are able to hold the heart with digitalis, and on the effect of quinidine. A patient with fibrillation of the congestive type should be given rest in bed with digitalis in full doses. If the fibrillation persists after he is digitalized, as shown by the change in the shape of the T wave or as shown by the clinical improvement, or the coupled beat or the vomiting, he may be given quinidine.

Apparently we have in quinidine a very valuable remedy for auricular fibrillation. Our experience at the City Hospital has been about the same as reported by others. We help about half of the cases—some of them for only a day or two, some for a much longer period. We are inclined to think that quinidine is indicated and gives the best results in cases of short duration, where the irregularity is a cause of discomfort, either from heart failure or from its mental effect. The patient should be kept in bed and watched very carefully. It is better to have the patient in the hospital where the effect of the quinidine can be checked up with the electrocardiogram.

Nurses should be given a stethoscope. It is impossible to get the heart rate of a fibrillation by the radial pulse.

Patients with cardio-vascular syphilis come to us when they are in the late forties or early fifties. They complain of precordial pain and shortness of breath. Dr. Levine has found that syphilis attacks the aorta rather than the myocardium. They have a diastolic and perhaps a to and fro murmur at the base. The Wassermann is not always positive. They should have a 7-foot plate. Syphilitic heart disease differs from rheumatic in that the disease is progressive. The active process is going steadily on. Our only hope is to be able to stop it. We cannot restore the damaged tissue. I think that it is considered better treatment to give the iodides and mercury

before giving small doses of 606. We can always give an unfavorable prognosis.

As to the treatment of heart failure—one may have heart disease for years and not know it unless he has been told about it, and when a heart is unable to sustain one at the level at which he is accustomed to live, he has heart failure with shortness of breath, edema, cyanosis and orthopnoea, or he has precordial pain.

If the failure is of the congestive type we prescribe rest and digitalis, and a limited field of activity.

Digitalis is not given because there is a murmur, but because the heart is not able to do its work without help. There is one murmur that is an indication for digitalis and that is the systolic murmur of a relative mitral insufficiency. As the patient becomes digitalized the heart becomes smaller and the murmur disappears.

If digitalis is indicated, it should be given in sufficiently large doses to get its full therapeutic effect. It is better to use a preparation with which you are familiar, and which has given you results before. Then if you do not relieve your patient it is because you are not giving a large enough dose. Now and then you will find a patient in whom you get your toxic effect before you get your therapeutic effect. In these cases you have to depend on rest.

Heart disease should be prevented rather than treated. If we can prevent rheumatic fever by removing the foci of infection, or if we treat rheumatic fever with full doses of salicylates, and long convalescence, we will lessen the number of rheumatic hearts.

Important points in appraising a heart case are: (1) etiology, personal history, rheumatic, luetic or sclerotic. (2) structural damage done, valve lesions, size of heart, etc. (3) Functional state, amount of work that causes discomfort.

THE COURSE OF HUMAN DESTINY.

The Yale University Press is sending a circular through the mail setting forth the opinions held by Ellsworth Huntington, Research Professor of Geography in Yale University. He endorses the attitude of astrologers of old, who told the people that stars control human destiny. Dr. Huntington's assertions are founded on his explorations in Western Asia, supported by subsequent investigations in Mexico and Central America. From these observations he asserts that there is a definitely established fact of relationship between climate and human progress.

He will bring out in a book, entitled "Climate Changes: Their Nature and Causes," the theory that our climate is controlled by the sun spots, which are the result of conjunction of the planets and the approach of stars.

Charts have been made of the positions of the stars over a period of 140,000 years, 70,000 years in the past and 70,000 years in the future. Past history, it is claimed, shows that

events of the past correspond with certain positions of the heavenly bodies, and since astronomy can plot the relation of these bodies in the future, coming events can be foretold. This is interesting, if true.

BOARD OF HEALTH OF PORTLAND, ME.

The annual report of the Board has come to hand and shows that the death rate for this city is 14.39. Tuberculosis (all forms) shows a death rate of 71.8 per 100,000 population, cancer shows 147.7, organic disease of the heart 155, pneumonia and bronchitis 122.8, nephritis 123.8; deaths of infants under one year had a rate of 58 per 1,000 live births. This Board has taken measures to study the possibility of the introduction of plague by infected rats and has presented in this report cogent reasons for the adoption of preventive measures on our sea coast. Although 2,010 rodents taken in Portland were killed and examined at a cost of \$1,950.18, no plague infected animals were found, but the prediction is made that the Atlantic sea coast will not long enjoy the present freedom from plague.

The report shows that the common problems of preventive medicine are being efficiently dealt with in this city.

WEEKLY HEALTH INDEX.

The Department of Commerce at Washington reports that telegraphic returns from 63 cities, with a population of 27,000,000, for the week ending September 9, indicate a mortality rate of 10.4 as against 10.7 for the corresponding month last year.

The highest rate (18.8) appears for Birmingham, Ala., and the lowest (4.5) for Springfield, Mass. The highest infant mortality rate (15.4) is for Fall River, Mass., and the lowest for Salt Lake City, which reported no mortality.

The mortality rates for June, July and August, of this year, are lower than for the same period of last year.

VISITS OF JAPANESE MEDICAL LEADERS TO AMERICA.

SOME of the most eminent physicians and surgeons of Japan will visit the United States and Canada, probably next spring, in response to an invitation from Dr. George E. Vincent, president of the Rockefeller Foundation, which has been accepted by the Minister of Education. According to the invitation from Dr. Vincent, the Japanese mission is to be composed of four or five of the medical leaders, and about three months will be spent in visiting the principal

hospitals, universities, medical schools and other scientific centers there, during which time they are to be under the guidance of some leading medical men in the United States. As the guests of the Rockefeller Foundation, all the expenses will be met by the foundation. The selection of the mission is entrusted at the request of the Minister of Education to the Japanese Committee for the Furtherance of Graduate Medical Study in the United States, the chairman of which is Baron Sakatani and which comprises eight or nine of the leading physicians and surgeons of the empire. The invitation will be only one result of a movement now under way to bring the medical, surgical and scientific professions of America and Japan closer together. The same result is also being sought by means of scholarships awarded Japanese doctors for graduate study in American universities. Three Japanese students are already in the United States on such scholarship, two given by the Rockefeller Foundation and one by the Mayo Foundation.—*The Japan Medical World.*

THE PREVENTION OF PERITONEAL ADHESIONS.

TAKASHI KUBOTA, working in the Department of Surgery, Medical College of Kyushu Imperial University, Japan, claims to have demonstrated the value of papain in preventing peritoneal adhesions. He first produced peritoneal adhesions by irritating certain parts of the peritoneum and then used control animals subjected to the same treatment but applying solutions of papain to the irritated areas. His conclusions are as follows:

1. The local application of one hundred to two hundred thousand times dilutions of Koktol in physiological salt solution satisfactorily prevented the peritoneal adhesions in animal experiments.

2. Koktol has no toxic action with the doses I used.

3. Koktol in powder form is not deteriorated at dry heat of 100 c. for sterilization.

4. Applications of Koktol solution at the points of anastomosis of the gastro-intestinal tract do not prevent from adhesion and healing of the wounds. However, the abnormal adhesions around the wounds were prevented by the applications. (Koktol is papain.)

BELGIUM AND THE VENEREAL MENACE.

THE National Council for Combating Venereal Diseases, London, states that during the war and the German occupation of Belgium, venereal disease spread in an alarming manner. The Government Board of Health has now worked out a new programme, with the coöperation of existing health organizations. The principal

measures consist in the free distribution of salvarsan and other drugs, the reinforcement of the sanitary staff and in the choice of specialists recognized by the Government to attend medical clinics and dispensaries.

Since coercion has not been deemed advisable in Belgium, a National League for Combating Venereal Disease has been formed, and is working with the help of these committees: medical, moral propaganda, and social assistance committees. The activities of these committees are outlined as follows:

(a) **MEDICAL WORK.**—Consists principally in treatment. It has been partly helped by the Government.

The League will have to build as many model dispensaries as possible, and invite all medical men to send their patients there for treatment.

The League will have to complete the training of the doctors themselves concerning the treatment of venereal disease; it will have a member on the University Board, so that the teaching of these diseases will have the place that it requires in the programme of the courses, and be made compulsory; it will organize special courses for young doctors; it will see that new legislative measures will be taken without delay against quack treatment and false advertisements in the papers.

(b) **MORAL PROPAGANDA.**—This commission will spread the knowledge of venereal diseases through the whole country and indicate the best means to prevent them, and to cure them.

This will be done by means of lectures, press articles, tracts, pamphlets, posters, etc.

Lectures will be organized all over the country.

They will be given in a series of three, as we consider that one single lecture does not make a deep enough impression.

One will be on syphilis, one on gonorrhoea, and one on either moral culture or social help, or combining both subjects.

These lectures will vary according to the audience; to the general public, to medical students, to young men at universities, to boys before they leave college, to teachers, to soldiers and officers, to workmen, to women, and to parents.

Each member of the audience will be asked for his name and address, so that pamphlets and tracts may be sent to him later on, which will keep his interest awake on the subject.

The lecturers will be either voluntary or paid by the League.

(c) **SOCIAL WORK.**—This commission will help the victims of venereal diseases, especially women and children.

Homes, hostels, and maternity hospitals will be started as soon as possible for patients suffering from this disorder, *crèches* and "*pon-ponnières*" for heredo-syphilitic children.

CHILDREN PAY THE PENALTY.

It is most unfortunate that the children, who have nothing to say as to what means shall be used for their protection against the preventable diseases, are, as a rule, the ones who pay the penalty for the misguided actions of those who are responsible for their proper care and protection.

And especially is this true in the case of the children of parents and guardians who are opposed to vaccination as a means of protection against smallpox. Such children may be well termed the victims of anti-vaccination propaganda.

For many years the history of outbreaks of smallpox has shown that those of the most serious character have always occurred in communities where anti-vaccination propaganda has been most effective.

For example, Dr. W. M. Dickie, Secretary of the California State Department of Health, tells us that there was a marked increase in the concentration of smallpox upon the age groups which have the highest proportion of unprotected persons. In support of this he presents some statistics bearing upon this phase of smallpox incidence in that state and covering the years from 1916 to 1921. These figures show that in 1916, 36.6 per cent. of the cases of smallpox occurring in that year were of persons below fifteen years of age. In 1921 this proportion had increased to 45.8 per cent. And then he adds that, as the number of unprotected children of school age increases through the opposition and influence of anti-vaccinationists to compulsory vaccination as a condition to school attendance, the number of smallpox cases among the young also increases.

The following figures, prepared by Dr. Dickie, tell their own story and also fully support the contention that smallpox incidence is always highest among those unprotected by vaccination:

*Year	Total No. of Cases	Cases in Persons from 5 to 14 Years of Age
1916	205	50
1918	654	191
1919	1,560	531
1920	4,218	1,471
1921	5,278	2,126

*Data for 1917 not obtainable.

It is also of interest to note that in 1920, 341 of these cases were in children under five years of age, and in 1921, 392 cases under five.

After a study of the above carefully compiled and authentic figures and the statements in connection therewith, would it not be a wise thing to have your children properly vaccinated and thus protect them against this loathsome disease? —[Chicago School of Sanitary Instruction Bulletin.]

THE LIMITED SELECTIVE EMBARGO ON SYNTHETIC ORGANIC CHEMICALS AND MEDICINALS.

An appeal has been sent to physicians of America to use all proper influence with Congress to secure the continuance of the dye and chemical content act in order to give sufficient time for a thorough study of rates of duty required to protect American industry along these lines.

If any physician is uncertain about the best course to pursue, he will be aided in his consideration of the subject by reference to the editorial which appeared in the *Journal of the American Medical Association*, August 12, 1922.

Obituaries.

NATHANIEL R. PERKINS, M.D.

DR. NATHANIEL ROYAL PERKINS, assistant secretary of the Massachusetts Board of Registration in Medicine, dropped dead in front of his home in Dorchester, September 22, 1922.

He was born in Plainville, Vt., Sept. 10, 1847, attended the Newbery Seminary and later the Hahnemann Medical College in Philadelphia, graduating from the Boston University School of Medicine in 1876. He settled in practice in Winchendon, moving to Dorchester in 1890, where he had practised until the time of his death. He became a member of the Board of Registration in Medicine in 1902 and had served continuously since. In 1888 he was a member of the legislature, representing the town of Winchendon. He was a Mason and a member of the Massachusetts Homeopathic Medical Society since 1880.

He is survived by his widow, one daughter, and a son, Dr. R. L. Perkins, of Harrisburg, Pa.

He was always deeply interested in the affairs of that society having served as President, and on important committees. He delivered the oration at the last annual meeting as a member of the Board of Registration in Medicine. He was interested in all matters which might be of assistance to reputable practitioners. With these objects in view he was an ardent advocate of reciprocal relations between the States. Since acting as assistant secretary he was ambitious to develop the employment of practical methods.

PHYSICIAN MURDERED WHILE GIVING FIRST AID.

DR. HENRY VOSE REYNOLDS of Brookline was shot and killed by a negro janitor in front of 1768 Beacon Street, Brookline, while giving first aid to victims of previous charges of the janitor's double-barrelled shotgun, on the evening of September 21, 1922.

Dr. Reynolds happened to be passing the spot in his automobile when the janitor of the apartment building, who had been recently discharged and had been drinking, opened fire from the basement door on his employer and a policeman without warning. Seeing the two wounded men fall to the sidewalk, Dr. Reynolds sprang from his car and ran to their assistance, calling to the janitor not to fire again. The next shot killed Dr. Reynolds instantly, while bending over one of the men, the entire charge lodging in his neck and shoulder.

Dr. Reynolds was born in Canton sixty-one years ago, and took his M.D. at Boston University School of Medicine in 1885. After taking post-graduate courses at Harvard Medical School and in Vienna, he settled in practice in his native town, then moved to Dorchester and joined the Massachusetts Medical Society in 1889. He moved to Brookline in 1916 and had practised there since. He was examiner of the State Mutual Life Insurance Company and was active in Masonic affairs. He is survived by his widow and one married daughter.

NOTICES.

THE MASSACHUSETTS MEDICAL SOCIETY.

STATED MEETING OF THE COUNCIL.

A stated meeting of the Council will be held in John Ware Hall, Boston Medical Library, 8 The Fenway, on Wednesday, October 4, 1922, at 12 o'clock noon.

Business:

1. Report of Committee on Membership and Finance, as to Membership.
2. Petitions for restoration to the privileges of fellowship and reports of committees to consider such petitions.
3. Appointment of Auditing Committee.
4. Appointment of delegates to annual meeting of Vermont State Medical Society at Burlington, October 12 and 13, 1922.
5. Report of Committee on Membership and Finance, as to Finance.
6. Report of Committee to draft petition to the General Court for authority to hold a larger income.
7. Report of Committee on meetings of New England Medical Societies.
8. Report of the delegation to the meeting of the House of Delegates of the American Medical Association at St. Louis.
9. Report of the Committee on Public Health on definitions of the terms: "public health nurse" and "functions of the public health nurse."
10. Appointment of assistants to the Committee of Arrangements for the Annual Meeting in Pittsfield, June 12 and 13, 1923.
11. *Incidental Business.*

WALTER L. BURRAGE,
Secretary.

Boston, September 27, 1922.

Councillors are reminded to sign one of the attendance books before the meeting. The Cotting Lunch will be served in the Supper Room immediately after the meeting.

SUFFOLK DISTRICT MEDICAL SOCIETY.

MEETINGS FOR 1922-1923.

OCTOBER 18, 1922. Stated Meeting.
"Caesarean Section." Dr. John O. Polak, of Brook-

lyn, New York, Professor of Obstetrics and Gynecology, Long Island College Hospital. Discussion to be opened by Dr. P. S. Newell and Dr. R. L. DeNormandie. Lantern slides.

NOVEMBER 22, 1922. Combined Meeting of the Boston Medical Library and the Suffolk District Medical Society.

"Rehabilitation." "The Pay Envelope instead of the Park Bench." Introduction of the subject and certain preventive Surgical Measures, Dr. Fred-eric J. Cotton.

Certain Medical and Mental Aspects, Dr. Herbert J. Hall.

The State Institutions, Dr. John H. Nichols.

Certain Legal Aspects, Joseph A. Parks, Esq.

The Industrial Side, Dr. Francis D. Donoghue.

Occupational Therapy, Drs. E. G. Brackett and John D. Adams.

Physiotherapy, Dr. Frank B. Granger.

Discussion opened by Drs. Francis W. Anthony, of Haverhill, and James W. Sever, of Boston.

DECEMBER 27, 1922. "Surgical Lesions Occurring in Diabetics: their Peculiarities and Management." Dr. Elliott P. Joslin, Boston. An account of the experience in this field of the Major Hospitals of Boston, by members of the Staffs.

JANUARY 31, 1923. "Epidemic Encephalitis," Dr. E. W. Taylor, Boston.

FEBRUARY 28, 1923. "Colitis," Dr. Henry F. Hewes, Boston.

MARCH 28, 1923. "A Review of What Surgery Can Accomplish in Diseases of the Thoracic Organs, with a Forecast of the Future." Dr. Howard Lilienthal, New York.

APRIL 25, 1923. Annual Meeting.
"The Record of the past twelve years in Syphilology, with a Forecast of the Future." A series of 10-minute papers. Dr. C. Morton Smith, Boston, will pre- side.

Election of officers.
R. H. Miller, Secretary. J. S. Stone, President.

NORFOLK DISTRICT MEDICAL SOCIETY.

EXTRA SPECIAL.

There will be an extra special meeting of The Norfolk District Medical Society at the Roxbury Masonic Temple, 171 Warren St., Tuesday, evening, October 3, at 8.15 P. M. sharp.

The purpose of this meeting is to try to arouse interest in Schick Test and toxine-antitoxine immunization which is now receiving so much attention by the Health Departments of both the City and State.

The programme will cover many phases of the subject and has as speakers men of wide experience and much enthusiasm.

It behooves every member who has the health of the community and his personal interest at heart to attend this meeting.

The speakers are: Dr. Francis X. Mahoney, Commissioner of Health, Boston; Dr. John A. Ceconi, Epidemiologist, Boston; Dr. Eugene R. Kelley, Commissioner of Health, State of Massachusetts; Dr. Benjamin White, Director of State Laboratory; Dr. Edwin H. Place, Resident Chief, South Department City Hospital; Dr. William H. Devine, Director of Medical Inspection, Boston Schools.

Open Discussion. Collation.

The Censors meet for the examination of candidates, Thursday, November 2, 1922.

BRADFORD KENT, M.D., Secretary,
798 Blue Hill Avenue, Dorchester

AMERICAN PUBLIC HEALTH ASSOCIATION TO MEET IN CLEVELAND.

The Fifty-First Annual Meeting of the American Public Health Association will be held at Cleveland, Ohio, October 16-19, 1922. Headquarters will be at Hotel Statler.

The following sections will conduct programs: Public Health Administration, Laboratory, Vital Statistics, Sanitary Engineering, Industrial Hygiene, Food and Drugs, and Child Hygiene. There will also be special programs on Public Health Publicity and Education and Public Health Nursing.

An interesting part of the general sessions of the program will be a summary and conclusions from a survey of eighty-five city health departments, conducted by a committee under the chairmanship of Professor C.-E. A. Winslow. A second feature will be a symposium on the subject, "How Can We Safeguard Public Health from Political Interference?"

Reduced railroad rates have been granted to members of the Association.

Further information may be obtained from the Secretary of the Association at 370 Seventh Avenue, New York City.

Secretaries of societies are requested to forward notices of coming meetings for publication. Reporters will please forward early reports of meetings that have been held with a concise account of the salient features.

UNITED STATES CIVIL SERVICE EXAMINATION.

RESEARCH ASSISTANT IN CHILD HYGIENE.

Receipt of Applications to Close October 10, 1922.

The United States Civil Service Commission announces an open competitive examination for research assistant in child hygiene. Vacancies in the Children's Bureau, Department of Labor, at \$1600 to \$2000 a year, and in positions requiring similar qualifications, at these or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion. For particulars apply to United States Civil Service, Washington, D. C.

MARRIAGE ANNOUNCEMENT.

The marriage is announced of Dr. Richard H. Miller of 402 Marlboro Street, Boston, to Miss Georgina Mary Jardine of Moncton, N. B.

SOCIETY MEETINGS.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue. The incomplete details and omission of names of many societies is because the information has not been furnished, although the JOURNAL has requested information for publication. Free publication of dates of meetings may accommodate many members of societies. Several physicians have spoken of the importance of having a schedule of meetings published so that arrangements may be made for special meetings on dates which may not conflict.

It may be possible to adopt the custom of the publication of notices of stated meetings in the JOURNAL and if this is generally understood, secretaries of societies could save time and expense. If general cooperation can be secured this plan can be made permanent.

DISTRICT SOCIETIES.

Barnstable District: Hyannis, November 3, 1922, February 2, 1923, (Annual Meeting)—May 4, 1923.

Bristol North, Bristol South, Barnstable and Plymouth Districts will hold joint meetings sometime this fall.

Bristol South District: Fall River, November 2, 1922, May 3, 1923.

Eastern Hampden Medical Association: Springfield, October 5, 1922.

Essex North District: Haverhill, (Semi-Annual Meeting)—Jan. 3, 1923. Y. M. C. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Essex North, Essex South, Middlesex North and Middlesex South Districts will hold joint meetings October 18. Place undecided.

Hampden Districts: With Hampshire District in Holyoke. Regular meeting in October.

Norfolk District: Extra Special Meeting at the Roxbury Masonic Temple, 171 Warren Street, Tuesday Evening, October 3, at 8.15 P. M., during, to raise interest in Schick Test and Toxine antitoxine immunization. An exceptional list of speakers. Open discussion and collection.

Suffolk District: Stated Meeting, October 18, 1922. Combined meeting of Boston Medical Library and Suffolk District, November 22, 1922. December 21, 1922. January 31, 1923; February 28, 1923; March 28, 1923. Annual Meeting, April 25, 1923.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Hist. The date for each speaker has not been assigned.

Middlesex North District: Meetings Wednesday, October 25, 1922; Wednesday, January 31, 1923.

The four western districts plan to hold a joint meeting early in October.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

NEW ENGLAND TUBERCULOSIS CONFERENCE, Augusta, Maine.—September 28, 29 and 30. Sessions will be held at the State House. Headquarters at the Augusta House.

September 28. Speakers: Dr. Arthur L. Wallace, Dr. Stephen J. Mosher, R. V. Spencer, Miss Elena M. Crouch, Dr. Charles Duncan.

September 29. Speakers: Dr. E. O. Otis, Dr. R. B. Kerr, Dr. J. Pinckney, Basil G. Eaves, Dr. E. R. Kelley, Dr. E. D. Merrill.

September 30. Speaker: Dr. J. C. Cobb.

At noon a modern health crusade luncheon will be held at the Augusta Hotel. Speaker will be Harold W. Slocum.

Massachusetts Medical-Legal Society will meet Wednesday, October 4, 1922, at 2 P. M., at the Boston Medical Library. Ernest L. Hunt, Secretary.

October, 1922. Boston Tuberculosis Association. Tuberculosis Institute for Physicians will be held on October 6 and 6 at the Massachusetts General Hospital, Bernice W. Billings, Boston, Executive Secretary.

The New England Society of Psychiatry will hold its next meeting on October 5th, at the Connecticut State Hospital, Middletown, Connecticut. Readers: Dr. Walter Timme and Frankwood E. Williams, New York City.

New England Dermatological Society, Wednesday, October 11, 1922, at 3.30 P. M., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

The Fifty-First Annual Meeting of the American Public Health Association will be held at Cleveland, Ohio, October 16-19, 1922. Headquarters will be at Hotel Statler.

The American Association of Oral and Plastic Surgeons will hold their annual meeting at the Medical Library, Boston, on October 29th and 31st.

Clinical Congress of the American College of Surgeons will be held in Boston, Mass., on October 23-27, 1922, Franklin H. Martin, Chicago, Director-General.

Massachusetts Association of Boards of Health, October 26, 1922, Boston, Mass., W. H. Allen, Mansfield, Mass., Secretary.

New York and New England Association Railway Surgeons 32nd Annual Meeting at New York City, October 28, 1922, Donald Guthrie, Sayre, Pa., Secretary.

November, 1922. Massachusetts Society of Examining Physicians, (Date and place of meeting undecided), Hilbert F. Day, Secretary. National Cancer Week, November 12 to 18.

December, 1922. New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

January, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston, W. H. Allen, Mansfield, Mass., Secretary.

February, 1923. New England Dermatological Society Meeting, February 14, 1923, at 3.30 P. M., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

March, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary.

April, 1923. New England Dermatological Society Meeting, April 19, 1923, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston, W. H. Allen, Mansfield, Mass., Secretary.

May, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided). American Pediatric Society Meeting, May 21, June 1, and 2, 1923, at French Lick Springs Hotel, French Lick, Ind., H. C. Carpenter, Secretary.

June, 1923. American Medical Association, San Francisco, June 25-29, 1923, Alexander R. Craig, Chicago, Ill., Secretary.*

July, 1923. Massachusetts Association of Boards of Health, July 26, 1923, W. H. Allen, Mansfield, Mass., Secretary.

*Deceased Sept. 2, 1922.

SINS OF OMISSION AND COMMISSION.

Sir Robert Jones says that medical sins of omission and surgical sins of commission would both be prevented by a closer affiliation of these great branches of the medical profession.

Presidential address, Royal Society of Medicine.)

NUTRITION AND GROWTH IN RELATION TO TUBERCULOSIS.*

BY WILLIAM R. P. EMERSON, M.D., BOSTON.

THE statement that almost every child is infected by tuberculosis before he reaches the age of 18 ought to be accompanied by a further statement as to the effect of lowered nutrition in making active a dormant process. It is fair to say that the prevention of malnutrition means to a great extent the prevention of tuberculosis.

This preventive work must center in the home. We may bring public sanitary conditions to a high level, and overcome many other handicaps of serious import, but unless parents are made to understand the nutritional condition of their children, and how to keep them up to a normal standard of health, other efforts to save them from tuberculosis are largely vain. The task of bringing into the home this kind of health education is one of the things which our nutrition program undertakes to accomplish.

Through the nutrition class a well-tested program, based on careful clinical studies, is applied to the problem. The mere weighing and measuring of the children in a particular school will so focus attention upon the need of better conditions of growth as to bring about a marked improvement while the new impulse lasts. This

has led to the organization of many types of classes which make good beginnings, but lead to overconfidence on the part of uncritical sympathizers who feel sure that the way out has been discovered. It is not enough, however, to establish any kind of a class, and merely make a good start. The program should be planned so that the underweight children will continue their efforts until they have gained weight in proportion to their height, and have been trained in food and health habits which will prevent a relapse into their old condition.

The weight-for-height standard has been adopted after long-continued clinical experience as the best single test of nutritional condition that we have. To allow amply for natural variations in type and build, we have worked out a "safety zone" running from 7 per cent. under the average weight line to 20 per cent. above it. I have never found a child, or had one brought to me, whose weight-height ratio lay habitually below this zone, who did not show other clear signs of malnutrition.

The causes of malnutrition are many and various, but there are few cases which cannot be classed under one of the following five groups: Physical defects, especially naso-pharyngeal obstructions; lack of home control; over-fatigue; faulty food habits, with improper and insufficient food; faulty health habits. We have tried many programs to overcome these causes, but have secured adequate results only when cooperation has been effected between the four forces which bear an essential relation to

*Address given at the Sociological Section of the National Tuberculosis Association, Washington, D. C., May 5, 1922.

the child's health. These four forces are: the home; medical care; the school and other social agencies; and the child's own interest.

In this summary of the "five causes" and of the "four forces" to remove them, the whole ground of the nutrition program is covered, and further discussion is only an elaboration of details. While largely medical, the problem is also fundamentally social, and the home factor is of the greatest importance. For this reason, with the first step in the program we seek the coöperation of the parents. Every child who is found to be underweight needs a thorough physical-growth examination, and we make it a rule that this shall be given only in the presence of one or both parents. Their help is needed in the case history and social examination which follows, and if a mental examination is required it is important that they be fully informed of the results.

When the nutrition class is organized we again urge the presence of the mothers at the weekly meetings, and in the social and medical directions there given they receive the instruction needed in each individual case. Health propaganda and general talks on hygiene serve an excellent purpose, but the actual results achieved through them cannot be compared with this direct coördination of medical care with the home.

The physical, mental, and social examinations, when made with proper care, serve to locate the cause in a large percentage of cases. There are always, however, a small number of children—problem cases—who call for further study such as can only be given in a well-organized diagnostic clinic.

The first of the five causes of malnutrition is especially evident in groups of "contact" cases, possibly because the physician who is looking for signs of tuberculous infection is less concerned with other physical defects. I have found 60 per cent. of diseased adenoids and tonsils in a group of pretubercular children who had been under care for months, and in some instances for over a year.

In no other group do we find more serious disintegration of the home, with a consequent lowering of the standard of control, which ranks second among the causes of malnutrition. The mother's care is necessarily centered upon the patient who is suffering from tuberculosis. Often the very stress laid upon adequate diet for the sick person leads to less care for the other members of the family. The old custom of breaking up the home when the breadwinner was tubercular subjected the children to various influences which did not make for harmony and control when the little flock was brought together again.

In working with families of this class I have been surprised at the failure of those who had them in charge to give training in the essentials of health. For example, a mother who had been under direction for several years for

the care of a tubercular husband had not received elementary instruction in matters of hygiene and food for the rest of the family. She was thoroughly willing to learn, and responded immediately to teaching and suggestions on these subjects, bringing her children up to normal weight within a very short time.

Cases of overfatigue among children exposed to tuberculosis are almost too numerous to mention. This is partly a result of the lack of home control, but also due to failure to recognize that such children are unequal to the demands of a full school program. I have seen children who were on the waiting list of a sanatorium attempting to carry a school program planned for the full energies of a normal well child, and sometimes following extra studies, such as music and dancing, outside of school hours.

A further word is needed concerning the last of the "four forces" named—the child's own interest. This is one of the most important factors aroused by the nutrition class, and success is almost impossible without it. The child who has come into contact with tuberculosis needs encouragement. He requires training in mental hygiene, not only that he may coöperate in the necessary treatment, but that he may not be oppressed with the idea that his family is doomed by the great white plague. The child who is sent to a tuberculosis clinic is at once stigmatized by his companions as a "pip" case. A nutrition class or clinic suffers from no such handicap. This is one of the reasons why a tuberculosis association can work more effectively, with children, under some other name.

On the other hand, the national and state tuberculosis associations, through the hold which the fear of tuberculosis has upon the public, have acquired a prestige which is an important asset in promoting any kind of health work. Nowhere has our nutrition program been more effectively demonstrated than in the work of the local association of Rochester and Monroe County, New York. The recent exercises in that city, when 120 children were "graduated" with certificates of normal health, mark an epochal step in health work with children.

The nutrition program should eventually come under the Board of Education, but demonstrations such as this must first be made by private organizations in order to educate the public to support the new measures when at last the municipality takes them over. The position of the local tuberculosis association is particularly favorable for the work through its contact with the Board of Health and with all the societies concerned in social responsibility for the welfare of children.

The beginning made in Rochester with children of both school and preschool age very naturally extended itself to the young people who are entering industry. This period of life is one of great strain. The change from the comparatively simple life of home and school

to the serious demands of industrial life calls for advice and counsel in the matter of health which few agencies are prepared to supply. The unit of this larger health program is the nutrition class adjusted to meet the conditions of employment. Here, as in the school classes, the weight chart serves as the most reliable indicator of the effect of the day's work on the child's health.

Classes can be established by many organizations and in many places, but a central organization is needed for general supervision and clinical research in order that the best developments may be constantly available. A broad program reaching out into private and parochial, as well as public, schools must be planned to meet the needs of an entire community, and the problems which constantly arise must be met in the right manner in order to gain and hold that public support which is essential to progress and permanency of results.

Up to the present time the teaching of nutrition and growth in medical schools has made little progress. But a start has been made, and it will not be long before these subjects are recognized as a fundamental requirement for all who undertake the problems of the prevention of disease. Our nutrition institutes, held primarily for the training of workers, have proved of value in the general program of educating the public to the importance of this work. Besides "selling the idea" of the value of nutrition work, they afford a means of contact between various organized agencies and persons who have already had training and experience along lines that fit into a broad program.

Results of the spread of these ideas are apparent in many places. In the clinics the main purpose is not merely to determine whether a child is sick, but also whether or not he is growing properly. In the schools there is growing appreciation of the difference in working capacity between well children and those who are underweight, undernourished, and malnourished. In the homes, parents are more and more returning to the practice of watching the child's weight throughout the growing period, instead of disregarding this important factor after the age of infancy.

Another important by-product—if I may use the term—is the reorganization of the home effected through the nutrition class. This is a result of the greatest significance. Through the instruction given to mother and child together we find that when we have rehabilitated a child we have also rehabilitated a home! A spirit of mutual helpfulness uniting parent and child makes for order and sanity. Such a home is a unit of strength in the community. Instead of chaos and anarchy, there is a condition of trust and security which makes for right living.

Every one of the "four forces" discussed must be recognized and applied in a comprehensive health program, but the keystone of the

structure lies in homes of the right kind. Back of the clinic, the school, the industrial center, the summer camp, the preventorium, the sanatorium—back of every agency concerned in the welfare of children—must be home coöperation. This is the best means of vitalizing child health work, and of preventing malnutrition and tuberculosis. Divorce the home from the other factors, and the greater part of what we are attempting meets with failure. When the child is made well in his own home, both mother and child learn the essentials of health, and through this health education the reconstruction of the home is accomplished.

EXHIBIT A—LANTERN SLIDES.

GROUP 1. Photographs showing defects and deformities resulting from malnutrition: Round shoulders, spinal curvature, fatigue posture, ptosis, flat feet, lines under eyes, and anxious expression indicating depression and mental retardation.

GROUP 2. Views of an open-air school in Pawtucket, R. I., where 16 children were provided with mid-morning lunches, Eskimo suits, cots for rest periods, playroom, and special teacher. The results of a year's work were a total gain of 2 per cent. less than the average rate of growth for the group because two of the essential forces were omitted, *viz.*: medical care, with complete examination, and home coöperation with the school program.

GROUP 3. Group photographs of graduates from nutrition classes in the Rochester public schools.

EXHIBIT B—A NUTRITION CLASS ORGANIZED BY MRS. R. K. EARLE.

A class of 14 children used to illustrate various points, among them the following:

A child who had received extraordinary care during infancy, but at the age of twelve was twelve pounds underweight for height. Her mother brings her to the nutrition class regularly, and is very helpful in assisting other mothers to bring their children up to normal. A case of splendid coöperation once the need was known.

A boy, the son of a physician, whose condition was not appreciated until he received the complete physical-growth examination. This showed curvature of spine, fatigue posture, and other defects.

A boy who failed to gain for a whole month during his mother's absence from the city. On her return he made a good gain.

Other children showing malnutrition due to over-fatigue from too great school pressure or too many outside interests; also cases due to faulty food and health habits.

Sixteen nutrition classes are conducted in Washington, D. C., under the supervision of Mrs. Ernest R. Grant, of the Tuberculosis Association, co-operating with Dr. Joseph Murphy, Chief Medical Inspector of the Public Schools. A new class is to be started at the Juvenile Court at the request of Judge Sellars.

An interesting report is that of Miss E. S. Bailey, Nutrition Worker, showing the need of rest periods even during vacation. A class of 18 children who were warned against over-fatigue at this time, and took their rest periods faithfully both morning and afternoon, gained 44 pounds during a two weeks' holiday. Another group of 18 who did not receive special caution before the vacation gained only 7.7 pounds in the same period. On the return to school the first group lost 9.7 pounds, and the second group 3.6 pounds, showing the effect of school pressure.

Miss Anita J. Turner, Assistant Director of Physical Education, reports 195 colored children enrolled in nutrition classes, which are held each week in place of the hour and a half allowed for physical exercise.

EXHIBIT C—CHARTS.

100 charts of the first graduates from this year's Rochester, N. Y., class.

A city-wide campaign is being carried on in Rochester through public, private, and parochial schools, orphanages, summer camps, preschool groups, and working children in industry, under the supervision of Herbert J. Norton, Physical Director of the Public Schools, and Mrs. Ethel M. Hendricksen, Executive Secretary, Tuberculosis Association of Rochester and Monroe County.

SPECIAL TRAINING IN HOME NURSING.*

BY ALFRED WORCESTER, M.D., WALTHAM, MASS.

THE modern profession of nursing and the modern science of avoiding and destroying disease-producing germs have been the two great factors in the wonderful advance of medical practice during the last half-century. Together they have changed hospitals from dreaded pest holes into popular life-saving institutions, which have increased many hundred-fold. Fifty years ago no patient who could possibly avoid doing so went to the hospital. Nowadays it is quite the fashion to be born or to die there, and for surgical operations as well as for medical treatment patients go to the hospital as a matter of course.

What is the effect upon nursing of this trend toward community hospitalization? In the first place, it is important to remember that the early schools of nursing were organized as educational institutions,—in more or less close connection with the hospitals, it is true, but still quite separate from them. The first and most famous, the Nightingale School at St. Thomas's, the Massachusetts General Hospital School and the Bellevue School in New York, were thus organized. Some smaller schools in this country also began independently of the hospitals, but, so far as I know, only the Waltham Training School still follows the Nightingale School in retaining its independence.

The hospital ownership of its training school, although so profitable to the hospital, is nevertheless in many ways a hindrance to the advance of the nursing profession. No professional school can be thus subordinated without the sacrifice of its educational ideals. The labor of an apprentice learning a trade goes rightly to the profit of the master. But nursing is certainly not a trade, and yet it cannot be considered a profession while the product of the pupil nurses' labor goes to the support of an eleemosynary institution or into the pocket of the hospital's proprietor.

The student of a true profession must pay for her education either in cash or in work that is its equivalent, but such payment must go entirely to the support of the School. Formerly, all professional schools were thus supported, but such schools now depend more or less largely,

and in proportion to their excellence, upon their endowments. Large grants are being made for this purpose, but as yet very little has been given to nursing schools. The reason is plain. Educational funds cannot properly be given except to educational institutions, and this is one of the hindrances to the advance of nursing that comes from the hospital ownership of the training schools; but there is another hindrance even more serious.

It is not for the hospital's interest to train its pupil nurses for any other service than that needed in the hospital, and until a scarcity of applicants forced them to arrange for wider training, by combining with other hospitals or with visiting nursing institutions, even the special hospitals contented themselves with giving diplomas. This was an injustice both to the nurses and to the public, for graduates in nursing, as in medicine, are supposed to have had an all-round professional education, and not merely training for service in some specialty. Furthermore, between the hospital and the training school there is a conflict of interests; it is to the hospital's advantage to keep the pupil nurse in the work she has already learned to do well, while for the pupil's own sake her service should be changed as fast as she acquires proficiency. Were this educational principle followed, the usual course of hospital training might easily be shortened.

In the hospital ownership of the training school the most serious detriment is that the nurses during their pupillage are not trained for the kind of service most of them afterwards have to undertake, which is the nursing care of patients in their own homes. Although only hospital training can fit a nurse for hospital service, and although the fundamental principles of nursing can be taught in the wards, it is nevertheless true that hospital training alone does not and cannot fit a nurse for equally excellent home nursing service; and the great reason for the prevailing distaste of graduate nurses for private nursing is that most of them have not been adequately educated for it. Every nurse likes best to do what she can do best. If, for instance, she has proven her efficiency as an operating-room assistant, naturally she prefers such service to that of nursing a patient in his own home, unless, indeed, in the rare instances where the home has to be transformed into a temporary hospital for some surgical operation.

Probably few graduate nurses recognize their lack of special training in home nursing as the real reason of their distaste for it, and, in fact, there are other good reasons. For instance, private nurses are often employed by rich families where only lady's maid service is needed; too many hours of service are often expected; too little time is allowed for the nurse's recreation and sleep. Sometimes the food given is insufficient. Other members of the patient's family are not always agreeable associates, but all these reasons, and others like them, for the

*An exhibit before the Middlesex County Nurses' Association, May 27, 1922.

prevailing dislike of graduate nurses for home nursing, are only subordinate. The real reason is, as has been stated, that more than hospital training is necessary to fit a nurse for perfect service in her patient's home, and very few nurses have had this extra training. If they have acquired proficiency as private nurses, it has been only in the hard school of experience, and at great cost both to themselves and to the families served.

What, then, it will be asked, is this necessary special training for home nursing? Obviously, only an outline of it, and the general principles involved, can be given within present limits.

There is no need of dwelling upon the necessity of getting along with only scanty or makeshift material, for the nurse's mother wit and common sense will triumph over such exigencies. Of far more importance than this usual shortage of proper material is the necessity of a self-dependence that cannot be acquired in hospital service where head nurses and house officers can be summoned to decide doubtful questions. Perhaps, out of the dim recesses of her memory the nurse alone must recall, if not the precise procedure, at least the general principle upon which her proper procedure depends. Fortunate for her if this first lesson in self-dependence comes while still a pupil nurse, before she is expected to know everything, and when from her instructor's next day visit she may receive competent endorsement or criticism of what she has done.

Training in the hospital teaches the nurse, besides her duties to her patients, her proper relation to the doctors, to her superiors, to her classmates, and to her juniors; but all she there learns of her proper relation to her patients' anxious families is how to shoo them out when visiting hours are over. In home nursing the sooner that particular lesson is unlearned the better, for success there depends upon utilizing for her patient's sake every anxious relative, all the friendly neighbors, and especially the servants. This requires an immense amount of tact. Some fortunate individuals are naturally tactful; some are not. But tact is acquirable; it is merely the effective expression of kindness.

Management of the family for the patient's advantage can be learned far more easily among those of moderate means than in wealthy homes. In this respect the pupil nurses, who generally are employed where high-priced graduate nurses could not be afforded, have a distinct advantage. Before graduation, before she is expected to know everything, it is far easier for the nurse to begin home nursing on a proper footing,—as the helper rather than as the superintendent of the family. Often the private nurse's greatest chance of helping, certainly at first, is in just standing ready and not in immediately supplanting the anxious amateurs who, of course, hate to surrender the care of their loved one.

"They also serve who only stand and wait."

Even if the nurse does know far better than the wife or mother how to take care of the patient, she does not care for him as they do, and for that very reason their clumsiness carries more comfort than her skill. The rough hands of the laborer may feel far tenderer to his suffering wife or child than the softest hands of the stranger nurse. Therefore, the nurse who has been trained only in the wards, and who considers herself in the same supreme charge of her private patient from the moment she enters his home, often fails not only to do what is best for the patient, but also often hurts the feelings of his family. Between assuming all the nursing service and undertaking that part of it which the family perhaps only gradually can be convinced they cannot so well perform, there is a vast difference; and the recognition of this essential difference,—between excellent and unacceptable service in home nursing,—is a hard lesson for fully trained nurses to learn. It is far easier learned by pupil nurses, and that is the great reason why pupil nurses' service is often preferred by families who do not even think of the greater expense of graduate nurse service.

In the wards the patient is considered only as an individual. In his home he is far more than that. The whole family is the real unit, and unless the home is made into a hospital, it is not possible for the nurse to give all her attention to the patient while ignoring the other members of the family. Sometimes it is necessary to make this transformation; but, if not necessary, such procedure is rightly resented by the family, if not also by the patient. Why, then, should he not have gone to a hospital? What comfort or advantage has he in staying at home?

Home nursing thus demands of the nurse not the service she has been trained to render, but an entirely different service. She knows how to establish hospital *régime*, but that is just what she must not do. Instead, she must rescue the imperilled home. And it is unfair to her, and to the public, to send her out to such service without sufficient preliminary training.

In the wards nurses very properly are conspicuous in the foreground. In the patient's home the more inconspicuous they are the better. The highest praise of the home nurse is that, except for the smoother running of the household, one would never know there was a nurse around. And yet, while never being in the way, the home nurse must be always on the job, always alert to ensure that every possible thing is being done for her patient's comfort and recovery.

Services that can be performed by other members of the family, or that they can be taught to render, should be considered theirs by right. Therein lies their greatest comfort. This is especially true at the last, when the patient can-

not recover, and when even the highest skill is of no avail.

This faculty of self-effacement and of using others' anxious hands in the care of her patient can neither be taught nor acquired in the hospital. In the home, and only in the home, it can be, and the question is,—when?

The foundation principle of a nurse's education and training is that, before she is given any particular service, she shall be taught how to perform it, and so far as possible the reasons for doing it in that way. And her practice is then to be supervised until her work can be depended upon. The same principle should be followed in training a nurse for home nursing. This training can best be given during, not after, her pupilage, when she is teachable, and when her practice can be supervised by her teachers.

This method of preparing student nurses for home nursing has been employed in the Waltham School now for more than thirty-seven years, but it was not invented here. Sixteen years earlier in Lausanne, the School of La Source was founded upon the same principle which is still maintained there. In 1895 our Training School had the benefit of Florence Nightingale's criticism and advice. Her subsequent letter to our nurses in its frame hangs there on the wall. She deplored, even then, the prevailing trend towards the over-hospitalization of nursing to the neglect of home nursing. And she strongly advised us to take for our model the Metropolitan and National Nursing School. The special characteristic of that school, which was chosen as the model for the training of the Queen's Jubilee Nurses, was in the preliminary training of its pupils in home nursing before they were sent to the hospitals for further training. Only such as made good in this preliminary course were retained. After one year in the hospitals they came back to the school for further training in home nursing.

For now a full half-century I have been especially interested in nursing; I still consider it the most important adjunct to my own profession. As a boy I sometimes served as the night watcher of my sick school fellows. I knew Dr. Susan Dimmock, and some of her trials in establishing the first training school in this country. I have studied many of the famous schools here and abroad, and without further apology I offer these as my

CONCLUSIONS.

1. The greatest need of nursing service is now, always has been, and always will be, in the home of the patient.
2. For home nursing, special training is necessary.
3. This special training can be given only in the home.
4. And it can best be given during the nurse's pupilage.
5. It is unfair, both to the public and to the

pupil nurses, for a training school not to include this special training in its curriculum.

AN INVESTIGATION OF THE RELIABILITY OF LABORATORY TESTS AND A DISCUSSION OF TECHNIQUE OF LABORATORIES IN AND NEAR BOSTON.

PART 3.

MILK COUNTS.

A COMPARISON OF REPORTS FROM SEVERAL LABORATORIES ON IDENTICAL SPECIMENS.

The bacterial examination of milk has become one of the most important of health laboratory tests. However experts may disagree as to the healthfulness or harmfulness of bacteria in milk, there remain certain important facts which cannot be denied. All other circumstances being equal, milk produced under sanitary conditions contains fewer bacteria than that produced under unsanitary conditions. Milk kept cold contains fewer bacteria than milk not kept cold, and fresh milk contains fewer bacteria than stale milk.

The milk bacterial count, then, is an index of the cleanliness of production, the proper cooling of the product and of its freshness, and a high count indicates a failure in one or all three of these conditions.

Considerable criticism has been brought against the bacterial count of milk because of the varying results obtained when split specimens have been submitted to different laboratories, and it is well known that variations in the media used and in the technique will produce wide divergence in the results.

The object of this series of tests was, first, to learn the technique in use in the various laboratories in this vicinity and to compare the results obtained, then, if possible, to adopt uniform technique and again compare results.

Twelve laboratories agreed to coöperate in milk counts, but because of the distance of some of these from Boston the work was carried on for the most part by but nine.

The twelve laboratories are as follows: Boston Health Department, Brookline Health Department, Brockton Health Department, Somerville Health Department, Wellesley Health Department, Alden Brothers, Boston Biochemical Laboratory, C. Brigham Company, Harvard Medical School Bacteriological Laboratory, H. P. Hood & Company and D. Whiting Company.

Questions concerning the technique in use in these laboratories were answered as shown in the following table:

TECHNIQUE IN USE FOR BACTERIAL EXAMINATION OF MILK SAMPLES.

Laboratory	Microscopic estimate of bacteria	Method	Percent of plating saved	Percent of agar used for plates	Reaction of media	Meat Juice or Beef Extr
A	at times, not often	Slack	0	1-1/2 %	+1.5 Fuller's scale	Beef Extr
B	Yes	"	0	"	+1.5 to +1.	Meat Juice
C	"	"	Raw Milk 75%	1%	+1.5	"
D	"	Slack Breed	20-25%	"	+1.	"
E	"	Slack	0	"	-	Beef Extr or Dehydrated
F	"	Slack Breed	90%	"	+ 1.5	Dehydrated
G	No	-	-	1.2 to 1.5%	+1.5 to +1.	Beef Extr.
H	Yes	Slack	0	1.2%	+1.4 or +1.5	Meat juice
I	No	-	-	1%	+1.5	"
J.	Yes	Slack	0	"	+1.5	"
K	"	"	33%	"	+1.5	"
L	No	-	-	1-1/2%	+1. to +1.5	Beef Extr

The principal point of difference in the technique is in the composition and reaction of the media used.

For the first and second series of tests six specimens each were submitted, care being taken to keep them well iced and to deliver to the laboratories as quickly as possible. The results are shown in Tables I. and II.

Discussion of Milk Tests.—Tables 1 and 2.—Table No. 1 shows what discordant results may be expected when counts are made with varying media and technique. Laboratory D reported such consistently abnormal low counts that inquiry was made into the method of media making, and it was discovered that on account of an error in titration calculation, which evidently had been followed for years, this laboratory was working with an alkaline medium.

Other counts are so far wrong as to indicate serious technical error. For instance, Laboratory F's report on Samples 1 and 2, or Laboratory I on Sample 6.

Wide as the variations are, however, if we consider the results only in relation to the Boston Health Department standard of 500,000 to a c.c., it will be found that out of fifty-four reports but seven are in error, and three of these are from Laboratory D.

Table No. 2 shows the results of another series of tests. In this series there is a closer approxi-

mation of similar conditions since several laboratories obtained media from the Boston Health Department Laboratory.

Laboratory F again reports counts on two samples, 5 and 6, which are difficult to explain, except by errors in technique. Laboratory D shows a similar report on Sample 2, and Laboratory A on Sample 4.

Judging the fifty-four reports from the 500,000 per c.c. standpoint, but two errors are shown: Sample 4 by Laboratory A, and Sample 5 by Laboratory F.

Technique for Milk Counts.—At a conference with seven of the cooperating laboratories represented it was unanimously agreed that a more uniform technique should be established and it was advised that laboratories of this vicinity use for the present as a medium for milk counts a meat-juice medium rather than one made with beef extract or other substitute; that this medium contain 1.2 per cent. agar, and, until such time as the laboratories shall become familiar with the hydrogen-ion titration of medium and shall agree upon the optimum reaction, the reaction shall be established by titration, using phenolphthalein as an indicator, and shall be +1.5 Fuller's scale.

Plates shall be incubated forty-eight hours at 37° C. in an incubator containing water.

Earthenware tops to Petri dishes may be

used in preference to glass tops, in order to control spreaders as far as possible.

Dilution water bottles must be filled sufficiently to overcome the loss by evaporation during sterilizing.

It was also agreed that as soon as time had been allowed for the various laboratories to conform to these requirements another series of tests would be run, each laboratory to report on but two dilutions, 1-100 and 1-10,000, all 1-10,000 plates containing over 250 colonies to be reported "over 2,500,000."

The results of this third series of tests appear in Table No. 3.

While some returns in this report indicate technical errors (Laboratory E report on Specimen 2 and Laboratory A on Specimen 5—1-10,000 dil.), the returns as a whole are very uniform and show what can be done when like technique and media are used.

Considered from the standard of 500,000 to a e.e., there are no errors in this report, but every worker agrees on every sample.

Some such uniform methods should be universally adopted, methods which, as nearly as possible, will give the actual number of bacteria present per cubic centimeter in the sample tested.

(To be continued.)

Medical Progress.

REPORT ON OBSTETRICS.

BY ROBERT L. DE NORMANDIE, M.D., BOSTON.

ABDOMINAL PREGNANCY FOLLOWING HYSTERECTOMY.

McMILLAN and Dunn¹ report a case of abdominal pregnancy following a hysterectomy. In 1918 McMILLAN did a hysterectomy on the patient. In the following year she presented herself with an abdominal tumor, which they determined to operate upon.

Upon opening the peritoneum a thin amniotic sac filled with fluid presented. They then opened the amniotic sac and removed an eight and a half pound baby. The baby was dead and macerated. The placenta was slowly and carefully separated from the left flank under the spleen, practically incarcerated by the greater omentum. Considerable bleeding followed, but this was controlled by hot packs, and a stab drain opening over the left ilium was made. The patient went off the table in excellent condition. She made an excellent recovery in three weeks.

A year later she presented herself and she was found again to be pregnant. When she was about four to five months pregnant she had a sudden sharp pain in her left side and was found pulseless, very white, tossing in bed, knees

drawn up, abdomen distended. The patient was taken at once to the hospital and immediately the abdomen was opened. Two pints of clear blood were obtained in a sterile basin and (this was given back to the patient intravenously with a 2½% solution of sodium citrate. Examination of the peritoneal cavity showed a mass which presented the appearance of a normal uterus on the right side, with a short distal end of a right tube and about half of a normal appearing ovary. At the left side of this mass was the protruding amniotic sac with a bulging mass of bleeding placental tissue which had a strong attachment to the sigmoid flexure. The amniotic sac was ruptured and a boy baby weighing about four pounds was removed. The operator sutured all bleeding points and closed the artificial half uterus. The patient died very shortly afterwards.

In the discussion of this case, which was presented before the Chicago Gynecological Society it was shown that a complete hysterectomy had not been done, as was thought at the first operation.

OBSTETRICAL PARALYSIS OF THE PERONEAL NERVE.

Whitman² reports a case of paralysis of the peroneal nerve from pressure upon the main trunk of the sciatic nerve in its intrapelvic portion. He says it occurs during prolonged or difficult labor, either from direct pressure of a large head in a small pelvis or from trauma by application of forceps. In looking over the literature on the subject, Whitman finds very little about it.

He reports the following case: The patient, aged 43, complained chiefly of paralysis of the left foot. She had been married seventeen years and had seven children alive and well, and two stillbirths. The present illness dates from eleven weeks ago. Labor began on a Friday night and continued until Sunday morning, when at ten o'clock forceps were applied and child delivered with considerable difficulty, weighing ten and a half pounds. Patient at once complained after delivery of great pain in both legs, and inability to move the left foot. Pain gradually wore off, and on the eighth day postpartum she attempted to get up, but was unable to walk because of the foot giving way under her. Since then she has been doing her work, supporting herself by clinging to the furniture. About one month ago power began to return to the flexors of the toes and the calf muscles, which have steadily been growing stronger. No disturbance of sensation.

Physical examination showed on the left side there is a drop foot, resulting from complete paralysis of the extensors of the toes, the tibialis anticus and posticus and the peronei. The flexors of the toes and the calf muscles are apparently normal. No disturbance of pain or temperature sensations, superficial or deep. Mo-

tion of both hips is free and painless. No sign of injury to the sacro-iliac joints or to the pelvis.

Whitman says that the diagnosis lay between two possibilities. Injury to the main trunk of the sciatic nerve where it crossed the pelvic brim, or injury to the peroneal nerve where it winds about the head of the fibula, from compression of the strap in the leg-holder. The second injury is much the more common, but in this case Whitman thinks that it was due to the first cause, because the tibialis posticus was paralyzed.

The patient was given a brace, and with the help of baking and massage and passive motion improvement in the gait was steadily seen, but no muscular improvement whatever was noticed.

Whitman states that the prognosis as to complete recovery in such cases should be extremely guarded, and he suggests that immediate orthopedic and neurological examination should be made, and suggests that in these cases proper apparatus should be immediately applied to prevent deformity.

The article closes with a list of references on the subject.

UTERO-PLACENTAL APOPLEXY IN ACCIDENTAL HEMORRHAGE.

In a most interesting paper Willson³ goes over the history of accidental hemorrhage. He reports in his article a case which he had in his own practice and then in detail analyzes the clinical and pathological data of sixty-eight cases which he finds in the literature.

The case he reports is a typical one of accidental hemorrhage, the classical symptoms were all present. The diagnosis apparently was very easily made, and Willson performed a Caesarean section. On opening the abdomen a considerable quantity of blood-stained serum was found in the peritoneal cavity. The uterus showed a mottled ecchymotic look, the colors ranging from that of a normal uterus through blue almost to black. The discoloration was greater in the region of the left cornua. Both the anterior and posterior walls were involved. In addition to the discoloration, a peculiar fissured appearance was noted. The fissures seemed to run in the main parallel to the long axis of the uterus. The peritoneum was not torn through. The uterus contained over a quart of fluid and clotted blood. The fetus, which was dead, was removed. The uterus at first failed to contract and then acted better. It was finally closed by interrupted sutures. The patient went back to bed in poor shape and died three hours after the operation.

An autopsy was obtained and microscopic findings are of interest. Central necrosis of the lobules of the liver was present, showing especially a slight biliary pigmentation and slight fatty degeneration. The kidneys showed an acute parenchymatous degeneration of a marked degree, involving especially the convoluted tubules. The uterine musculature appeared normal

with the exception of marked hemorrhagic extravasation between the bundles of muscle fibers. The placenta was apparently normal with the exception of a slight hyaline appearance of the stroma of the villi.

Willson analyzes in detail the data he has found in the sixty-eight cases, and a short summary of his findings follows. The period of gestation was mentioned in only fifty-eight cases. As far as Willson could determine, five cases occurred in the seventh month, ten in the eighth month, twenty-one in the ninth month, and twenty-two cases at term. In regard to the symptoms of toxemia, albumin was present in large amounts in forty-four cases. The blood pressure was only mentioned in nine cases, and in these nine the systolic pressure varied from 100 to 280. In seven cases there were no symptoms of toxemia, while there were definite symptoms of toxemia noted in forty-eight cases. Of the sixty-seven cases where the character of the bleeding could be determined, forty-six showed frank or combined type of bleeding. In thirty-six cases the placenta was separated completely, in twelve it was only partially separated, and in the others it was not noted.

Patients were delivered by the Porro operation twenty-one times, twenty-one times by conservative Caesarean section, Abdominal hysterectomy without opening of the uterus four times, vaginal hysterectomy twice, abdominal hysterectomy for rupture of the uterus once, extraction of the fetus by vagina, spontaneous delivery four times, abdominal hysterectomy to control postpartum hemorrhage was done three times, and three patients died undelivered. There were thirty-eight maternal deaths, and sixty-two fetal deaths. Of the children that survived, all were delivered by Caesarean section, there being no case in which the fetus survived through delivery by the vagina.

Willson goes into detailed analysis and study of the pathological data. In speaking of the myometrium, he calls attention to the constant finding of a hemorrhagic process present under the peritoneum. The observations regarding the condition of the muscle fibers themselves are rather contradictory. The decidua show changes which are always more marked in the decidua basalis than in the parietal decidua. The blood-vessels showed no uniformity, except the fact that they were markedly congested. In twenty-two cases out of thirty-one, it was noted that there was marked intraperitoneal effusion. The broad ligaments were involved in twenty-six, the tubes in eleven, and the ovaries in four cases. The placenta has not shown any marked pathological changes.

Willson reviews the theories regarding the causation of accidental hemorrhage, and puts forward himself the hypothesis that there is a hemorrhagic toxin, liberated by the placenta, which produces its maximum effect locally at the site of its inoculation, so to speak, and sec-

ondarily produces manifestations of a general toxemia.

Willson closes his article with a long bibliography on the subject brought up to date.

TREATMENT OF PREGNANCY COMPLICATED BY VALVULAR HEART DISEASE.

Heaney⁴ writes of the method of managing pregnancy complicated by valvular heart disease, from an obstetrician's point of view, and takes a very conservative attitude in regard to the way they should be delivered, bringing up the point that not only must the patient be delivered in the safest way, but that the post-delivery convalescence is as important as the delivery itself. He warns of the results that come from doing Caesarean section on all heart cases, and comes to the conclusion that physicians are not justified in refusing pregnancy to women with accidental or symptomless heart murmurs, and gives a word of warning that women who have had recent broken compensation or broken compensation in a preceding pregnancy enter pregnancy greatly jeopardized and that Caesarean section is not a ready and complete solution of the delivery of a woman with a broken compensation, adding that abortion for heart disease should have sterilization added to it when this can be done with but little additional risk.

THE TWO-FLAP LOW INCISION CAESAREAN SECTION.

Beck⁵ brings forward a low incision for Caesarean section which he thinks is applicable after an efficient test of labor. He states that peritonitis was the cause of over ten per cent. of deaths of patients operated upon at the Long Island College Hospital after a test of labor, and in order to avoid this high mortality he has developed his so-called "two-flap incision." The uterus is exposed through a mid-line incision below the umbilicus. The peritoneum is incised transversely about two centimeters above the bladder. A lower flap is obtained by stripping the bladder off from the anterior surface of the uterus. The upper flap is made by gently passing a pair of scissors under the peritoneum. The uterus is incised in the mid-line after exposing the denuded area by retracting the two flaps. The extraction of the child is accomplished by the hand with downward pressure on the fundus. If necessary, forceps may be used to facilitate the delivery. Before separating and removing the placenta, a catgut suture is passed through the lower angle of the uterine wound, in order to prevent the uterus from sinking into the pelvis. A similar suture is placed in the upper angle of the incision. Traction on these two sutures brings the entire wound into view and protects the peritoneal cavity while the placenta and membranes are being removed. In certain cases the placenta and membranes may be forced down through the cervix into the vagina. The incision in the uterus is closed by two series of interrupted sutures. The upper peri-

toneal flap is brought down over the superior portion of the closed uterine incision, and secured by several interrupted sutures. The remainder of the denuded surface is covered by bringing up the lower flap above the original incision. In this manner the peritoneal flaps thoroughly seal the wound in the uterus.

Beck shows the charts of the twenty-nine cases operated upon according to this technique. Fourteen cases, Beck states from the chart, were probably not infected at the time of operation. Other charts show cases which had been in labor from ten to twenty-four hours or more, some with membranes ruptured and a number with vaginal examinations made. All the patients recovered, and in only eight did infection appear.

Beck's conclusions are that this technique will eliminate the consideration of elective Caesarean section in border-line cases of dystocia, and by permitting the use of an efficient test of labor, most of these patients will be delivered through the natural passages. The few that fail may, with some slight added risk, be delivered by the use of the technique he describes. He recalls that potentially infected cases frequently are not infected, and that whenever our opinion in this respect is erroneous, this technique does not sacrifice the non-infected uterus, but preserves the functions of menstruation and reproduction.

He finally concludes that his mortality from this operation will be less than ten per cent., and claims that the two-flap low incision Caesarean section should be given preference.

ACTION OF THE ECBOLICS IN THE FIRST STAGE OF LABOR.

Rucker⁶ has utilized the Voorhees bag placed within the uterus in order to study the variations in pressure that take place within the uterus in the first stage of labor, as the result of giving the drugs commonly used at this time. He records his observations graphically, but he does not go into the details of the technique used. His article contains several graphic records of the results following the use of various drugs.

He concludes that by this means there is presented an excellent opportunity to observe the action upon the uterus of the drugs commonly used in obstetrics. From his limited observations it would appear that hyosine has a moderate but rather constant ecbolic action in the first stage of labor. The action of quinine is more variable. His observations upon the action of strychnine, castor oil, ergotol and the fluid extract of ergot are too limited to warrant even a tentative conclusion.

In the cases in which pituitrin was used even in minute doses, there was a continued contraction of the uterus that varied from nine to thirty-five minutes in duration, and Rucker feels that this is probably the explanation of the many disasters that have followed its use.

PITUITARY EXTRACT AT THE BEGINNING OF THE THIRD STAGE OF LABOR.

Brodhead and Langrock⁷ gave to one hundred consecutive patients, immediately after the birth of the child, one c.c. of infundin, hypodermically, in order to ascertain its effect upon the delivery of the placenta. In 19 cases the placenta was expelled spontaneously. The minimum time in one case was four minutes, and the maximum time was eighteen minutes. In 78 cases Crede's method of expression was used. In three cases the placentae were manually extracted. In 26 cases the amount of blood lost did not exceed 30 c.c. The maximum lost in a primipara was 525 c.c., in a multipara, 1,230 c.c. The average amount of blood lost in all the cases was 135 c.c. In 77 cases the blood lost after the third stage was completed did not exceed 30 c.c. for a period of one hour following the delivery of the placenta. The maximum amount of blood lost in primiparae was 750 c.c., and in multiparae 850 c.c.

The authors feel that in the vast majority of cases the method as outlined is safe and valuable in minimizing the loss of blood. They also feel that the uterus must be observed just as carefully as when pituitrin is not given. The only drawback to the method is the possibility of irregular or hour-glass contraction of the uterus. The authors recognize the fact, however, that this complication occurs independently of the use of pituitrin, and they say that further investigation will be necessary to show whether this complication is directly attributable to pituitrin or not.

LOW CERVICAL CAESAREAN SECTION.

De Lee and Connell⁸ report 145 cases of low cervical Caesarean section with much the same technique as Beck describes in his paper. These authors state that this technique was used several years before Beck published his article. The main difference between the two techniques is that De Lee and Connell use a special knife to make the uterine incision and that they "reunite the fascia over the lower uterine segment with a special row of catgut sutures." They further use a vacuum pump in order to suck out the blood and liquor amnii from the operator's field.

From this paper one gathers that they would perform this operation in the great majority of cases where a Caesarean is indicated, reserving the old classical Caesarean section for special indications. They give to this operation the name laparotrachelotomy and claim the following advantages for it.

1. The cervix stands infection better than the fundus.
2. The lower portion of the abdomen is more resistant to infection.
3. The cervical wound is at rest and can heal in peace.

4. The healing of the cervix is better than that of the fundus.

5. There is relatively little danger of leakage of the lochia.

6. The incidence of adhesion is reduced almost to zero.

7. The possibility of rupture of the scar in subsequent pregnancy is reduced to the minimum.

8. By this technique the patient is given a real test of labor.

9. Abdominal hernia has not occurred.

THE END-RESULTS OF ABDOMINAL CAESAREAN SECTION.

King⁹ analyzes 117 Caesarean sections done at the Charity Hospital in New Orleans by twenty-five operators, and 33 private cases done by five operators. In these cases there occurred six ruptured scars. Two of these patients died, the others recovered, one having to have a supravaginal hysterectomy. King's article contains some interesting tables which are too complicated to abstract.

King comes to the conclusion that we should restrict rather than broaden our indications for Caesarean Section.

HEART IN PREGNANCY.

Smith¹⁰ reports a series of clinical observations which were supplemented by electrocardiographic studies, in order to determine what changes, if any, were induced in the heart by pregnancy. His article contains several electrocardiograms illustrating his investigations. His conclusions are as follows:

1. Pregnancy in itself does not cause cardiac enlargement.

2. Such evidences of cardiac enlargement as may appear under certain circumstances disappear under other circumstances.

3. Cardiac enlargement, in the latter half of pregnancy, can be simulated by the upward pressure of the gravid uterus.

4. There are no heart affections which are characteristic of, or incident to, pregnancy.

5. While pregnancy throws a load on the heart it is fully capable of adapting itself to this demand.

6. A definite history of previous infections requires that the expectant mother be closely observed for symptoms of masked heart disease.

7. Focal infections may cause symptoms of heart embarrassment in pregnant patients which might erroneously be attributed to pregnancy.

8. Definite cardiac indications for the interruption of pregnancy are rare. Even frankly diseased hearts will exhibit a surprising adaptability to the physiologic demands of pregnancy.

INTRAVENOUS INJECTIONS OF GLUCOSE IN TOXEMIA OF PREGNANCY.

Titus and Givens,¹¹ following their success in treating the toxemias of early pregnancy by the

intravenous injections of glucose, decided to try this treatment in cases of eclampsia.

The solution used contained usually 75 gm. of glucose dissolved in 500 c.c. of distilled water, and sterilized at 15 pounds pressure for thirty minutes. The rate the solution was given was controlled to a certain extent; the entire volume was introduced in thirty minutes, but the authors state that there was no indication of harm to a patient if a more rapid flow occurred. They prefer to give single doses, repeated as required, rather than to attempt a continuous flow for any considerable period of time.

Recognizing that the liver is the carbohydrate storage organ of the body and that, in fatal toxemias of pregnancy, it undergoes degeneration and necrosis, the authors endeavored to devise a test which would indicate the degree or extent of liver impairment. The test is as follows: A specimen of blood is taken for blood sugar determination and then a given amount of glucose is injected intravenously, taking a definite length of time for the injection, after which another specimen is taken for blood sugar. Blood sugars are then done at stated intervals and from them a glycemia curve is plotted.

The writers conclude:

1. That the usefulness of glucose and other carbohydrates seems to be based on the fact that in toxemia of pregnancy there is a carbohydrate deficiency in the maternal organism.

2. That disturbances in kidney function are probably secondary to the hepatic changes.

3. That as a result of intravenous administration of glucose, in cases that this was used, there was, in individual patients, immediate clinical improvement and a general lowering of the mortality rate.

4. That the usual autopsy findings in the liver of patients dying from any toxemia of pregnancy are distinctly altered if this treatment is used. Those portions of the liver lobules, which are ordinarily necrotic, are restored to a marked degree and, in most cases, a diagnosis of eclampsia could not be made from an examination of the liver sections alone.

5. That the regeneration of the liver cells after injection of glucose, at least partially, restores the normal functions of the liver, especially in respect to its action as the detoxicating organ of the body.

6. That from these investigations it is thought that the rate of absorption and storage of the injected sugar is an index of the condition of the liver.

STUDY OF THE SCAR IN REPEATED CAESAREAN SECTIONS.

Gamble¹² analyzes the cases of repeated Caesarean sections which have been done at the Johns Hopkins Hospital, with special reference to the healing of the scar, and the occurrence of rupture through it.

Gamble studies the cases under the following

headings: infection, suture technique, suture material, situation of the incision, incision into the placenta over the old scar. He gives most interesting detailed descriptions of twenty uteri that were removed, and his article is illustrated by photographs of some of the specimens obtained. Gamble states that at Johns Hopkins, patients are sterilized after the third Caesarean section, for it is felt that when a patient has been subjected to the risk of three major operations she should be relieved of the added danger of a ruptured scar which must inevitably become increased after each subsequent operation.

Gamble's conclusions are: A weak Caesarean scar may be due to a combination of factors, the most important of which is infection. A febrile puerperium does not give an absolute assurance of perfect wound healing. The uterine wound should not be closed, if possible, until firm contraction of the musculature has occurred. Usually fetal elements do not invade the uterine scar. The dictum "Once a Caesarean, always a Caesarean" can not be accepted without considerable observation. A patient, who has once been subjected to a Caesarean section, should enter the hospital several weeks prior to the expected date of confinement so that she may have the benefit of immediate operation should rupture occur.

TUBERCULOSIS IN A STILLBORN FETUS.

Whitman and Greene¹³ report of case of miliary tuberculosis in a stillborn fetus. Autopsy showed tubercular lesions in the lungs, with many caseous nodules. Microscopic lesions were also found in the adrenals, kidneys, ovary, and brain. The placenta also showed numerous caseous nodules. The writers were able to find 113 authentic cases of prenatal tuberculosis, and their conclusions are:

1. Prenatal tuberculosis has ceased to be a mere curiosity of the laboratory, and has become a pressing problem of the sanitarian.

2. The facts at hand are significant enough to command the active employment of every agency by which further facts may be elicited.

3. To the extent that the spread of the disease is due to prenatal, rather than postnatal, infection, present methods of control must be revised and amended, even at the expense of those sentiments of compassion and tolerant forbearance by which our present efforts are so notably handicapped.

CHEMICAL OBSERVATIONS ON THE TOXAEMIAS OF PREGNANCY.

In a most interesting, though highly technical paper, de Wesselow¹⁴ reports his studies of an attempt to estimate the value of chemical methods of investigation in the toxemias of pregnancy. Because the brunt of the damage, in these conditions, falls on the liver and kidneys, de Wesselow has tried by chemical exami-

ation of the functions of these organs during life to determine the extent and progress of the lesions. He reviews the work that has been done on estimating renal efficiency, which he feels is satisfactory. In dealing with the hepatic function he says that at present there is no simple and accurate method that is available. In his studies he made use of the following methods: In the blood, he studied the urea, the non-protein nitrogen, the fibrinogen and the plasma lipase; in the urine, the total nitrogen urea and the ammonia. The blood pressure was taken and the urea test, as shown by the concentration, estimated for three consecutive hours after a dose of 15 grammes. He discusses fully his findings of normal pregnancy, mild toxæmias, and eclampsies, not only in the light of his own studies but in conjunction with other investigators of the same subjects. His findings are all carefully tabulated.

He concludes that there appears to be no definite evidence that we can detect the presence of a liver lesion in these cases of toxæmia. In the limited number of cases studied there was no evidence obtained, but the methods employed, of a differentiation into groups, or were there any definite differences detected between those complicated by convulsions and those in which no convulsions occurred.

There was no evidence of the existence of an hepatic as distinct from a nephritic toxæmia of pregnancy. He further concludes that a definitely raised urea content of the blood, that is to say, under the conditions obtaining in pregnancy, a blood urea above 40 mgrms. per 100 c.c. is proof that the kidney is severely damaged, and is an indication for induction of labor. If the blood urea is not raised, the urea concentration test gives valuable evidence of the condition of the renal function, and when the figure obtained is below 2 per cent., termination of the pregnancy should be considered. In cases in which a low diastolic is present, chronic disease and a less complete recovery are suggested. de Wesselow says that by estimations of the renal efficiency, in the absence of any satisfactory hepatic function tests, by the methods suggested we may be able to arrive at definite criteria for interrupting the pregnancy and thereby favorably influence both the immediate and ultimate results of the toxæmias of pregnancy.

PREGNANCY AND HEART DISEASE.

Pardee¹⁵ in his studies of the fitness for pregnancy of patients with heart disease, has grouped these patients according to their reaction to exercise. He studies the patient's symptoms, when housecleaning and climbing stairs, to find out how much she is restricted in her activities by the appearance of shortness of breath or palpitation. She then is put through a test exercise which consists of standing with feet separated and swinging a ten-pound dumb-

bell, in both hands, from over her head to as near the floor as she can conveniently reach, repeating the movement about once every two seconds. Pardee says this test can be repeated twenty times without difficulty, but all cases must be carefully watched for any possible distress. By his observations he says a normal pregnant woman can do this test without distress and with only a slight sense of breathlessness. The pulse will quicken to 120 a minute, counting for the first ten seconds only, but at the end of one minute the respiration will be normal and the pulse nearly so. Patients who were not troubled by what they considered unusual dyspnoea or palpitation on exertion before pregnancy, and who did not develop this during the present pregnancy, provided they showed a normal reaction to the test exercise, were placed in Group 1. Those patients who were not bothered by unusual dyspnoea or palpitation before pregnancy, but who had complained of this during a previous or the present pregnancy, and who showed either a normal or moderate reaction to the test exercise were placed in Group 2. If these patients showed a markedly increased reaction they were placed in Group 3.

All patients who had unusual dyspnoea or palpitation on ordinary exertion, before pregnancy, and showed added symptoms during pregnancy, were put into Group 3. These patients showed a moderately increased reaction to the test exercise, but if the reaction was markedly increased they were put in Group 4.

Group 4 consisted of patients who had been troubled by unusual dyspnoea before pregnancy, and whose symptoms had been markedly accentuated during a previous or the present pregnancy, so that the patient had to remain in bed for a time. These patients all showed markedly increased reactions to the test exercise.

Under this grouping Pardee studied thirty-four patients. There were seventeen cases in Groups 1 and 2, and none showed serious signs of cardiac overstrain during labor. Two patients in Group 3 died, but neither was in labor, and the two that died in Group 4 were during or immediately after labor.

Pardee feels that this grouping is very useful in prognosis, and also of great help in the management of those pregnancies which fall into Groups 3 and 4. He feels that women who fall into these two groups should be allowed to undertake pregnancy only when there is some very special reason, or when they are ready to keep themselves under the constant supervision of a physician who is accustomed to handling such cases.

Book Reviews.

The Practice of Medicine. By A. A. STEVENS, A.M., M.D., 1106 pages. Philadelphia and London: W. B. Saunders Company, 1922.

There already exist many medical textbooks the contents of which are similar and presented in the same standard manner, and this "Practice of Medicine" differs from them in no essential way.

The author has indicated the important issues of the day, and, most desirably, has drawn only conservative conclusions. The work is complete and carefully prepared. The book is up to date, but except for this it serves no purpose not fulfilled by other good textbooks of medicine.

It is unfortunate that the author, with his extensive and serviceable clinical experience, did not avail himself of the opportunity of presenting the subject in a more modern manner, as is to be found in certain articles appearing in the Oxford and Nelson Systems of Medicine.

The few selected references are well chosen, yet, unfortunately, are incompletely given. The book serves a useful purpose in that it adds another good textbook of medicine to the list of those already published.

Submucous Resection of the Nasal Septum. By WILLIAM MEDDAUGH DENNING, M.D. New York: Surgery Publishing Co.

"This book is primarily a monograph giving in clear and concise detail the individual technique and results of the author. It is a helpful contribution to the subject.

"One could wish that the operative technique had been presented on a broader basis. The briefness of the article hardly warrants its publication in book form as an authority on the subject of 'submucous resection of the nasal septum.'

Diseases of the Eye. CHARLES H. MAY, New York: William Wood & Co. 440 pages. Price \$3.50.

A new edition of "May" has just been received from the publishers, William Wood & Co.

This book has long occupied a preëminent place as a manual in the field of Ophthalmology. The 10th edition is sure to make its place more secure with the student and the practitioner who desires a handy book on this subject.

The publishers have retained the same excellent form as in other editions.

Diseases of the Eye. GEORGE E. DE SCHWEINITZ, Philadelphia and London: W. B. Saunders Co. 832 pages. Price \$10.

De Schweinitz's new Ninth Edition, "Diseases of the Eye," presents the last word in this field of Ophthalmology. The work has been thoroughly revised and much new material added. The influence of the late war is apparent in many sections and is particularly shown in the department of plastic surgery.

The chapter on Skiascopy has been revised, as have several others. Among numerous new articles might be mentioned a section on Ophthalmoscopy, with Red-free Light, and also Verhoeff's method of Electrolytic Punctures for Detachment of the Retina.

This author's work has always been popular with the oculist and the new edition should enhance its standing.

The volume is published by Saunders and Co., so nothing more need be said concerning the typography.

AN EXPERIMENTAL STUDY OF METHODS FOR BRIDGING NERVE DEFECTS.
 WITH A DESCRIPTION OF A NEW METHOD OF AUTOTRANSPLANT (AXO-AUTOTRANSPLANT).

SACHS, E., and MALONE, J. Y. (*Archives of Surgery*, Sept., 1922). These authors write as follows:

Three methods of bridging defects in nerves have been studied by a combination of physiologic and histologic methods.

It has been shown that nerve fibers will grow down the trunk of a healthy nerve through a longitudinal incision without impairing its function and part of the fibers connect up with the peripheral end. It is, there-

fore, of distinct advantage to implant the central end of a cut nerve as well as the peripheral end.

On account of the branching of regenerating fibers, enough axons are produced when a nerve is cut longitudinally to fill the sheaths in the implanted nerve, indicating that in a nerve anastomosis, an end-to-side implantation is perfectly satisfactory. This confirms our clinical experience. We have for years practiced this method of anastomosis in faciohypoglossal anastomosis.

The test described by one of us (Malone) for determining that nerve fibers have grown across a point of suture has proved a valuable aid in determining at an early date whether or not a nerve is regenerating.

The study of cross-sections of nerves as well as the results following the method of auto-autotransplant described in this paper throw doubt on, and we believe disprove, the contention that peripheral nerves have an internal topography, as maintained by Stoffel.

Though absolute alcohol may inhibit to some extent the formation of neuromas, it does not absolutely prevent them.

The most important factor in a successful nerve anastomosis is the accurate approximation of the nerve ends so that there is no tissue between them which may interfere with the regeneration of the fibers. Every effort, of course, should always be made to bring them together in their original anatomic relation; but, owing to the presence of internal plexuses in nerves, it is not so essential as has been supposed heretofore. Whenever a nerve regenerates, whorls are formed at the regenerating end, consequently the central end of a fiber does not necessarily connect with its corresponding peripheral end.

The method of auto-autotransplant described in the foregoing pages for bridging defects too long to permit of an end-to-end anastomosis is to be preferred to cable transplants because no normal nerve has to be injured and the operation can be carried on in one field.

The method of choice for bringing large defects, whenever possible, is the double implantation method of anastomosis. Its advantage over the auto-autotransplant lies in the fact that some cylinders have only one suture line to grow through, while in the auto-autotransplant they all have to go through two suture lines. [E. H. R.]

AUTOGENOUS VERSUS HETEROGENEOUS BONE PEGS.

TARNOWSKY (*Surg., Gyn. and Obstet.*, Sept., 1922) writes as follows:

The clinical behavior of a beef-bone graft depends entirely on the relative activities of the osteoblasts and osteoclasts:

1. With proliferation of new cells from the living proximal and distal ends of the fractured bone keeping pace with absorption of dead cells from the graft, complete disappearance of the latter coincides with complete union of the fracture or filling in of the defect.

2. With hyperactive new cell formation and sluggish absorption, the graft constitutes a sequestrum which either eburnates and remains in a state of quiescence or acts as an irritant foreign body with sinus formation and periodic extrusion of dead bone spicules.

3. With hyperactive bone absorption and sluggish new-bone formation the graft disappears by combined extrusion and absorption before union or filling in of the defect has taken place.

The factors which enable us to attain the ideal, i.e., an even balance of absorption and proliferation, are: First, the thorough trimming off of dead bone proximally and distally with curette and chisel; second, firm approximation of the bone graft to living bone; and third, absolute asepsis.

Finally, it has seemed to us that the term infection, as applied to bone surgery, is too loosely used, and

that in many cases of so-called septic results we are merely dealing with type three, i.e., rapid necrosis of the graft without infection using the latter term in its perfect sense. In other words, subacute osteomyelitis, with no anti-body reaction on the part of the individual, should not be classed as an infection but as ordinary tissue necrosis. [E. H. R.]

CARBON TETRACHLORIDE IN HELMINTHIASIS.

McVAIL (*Ind. Med. Gaz.*, Aug., 1922) reports his experience with carbon tetrachloride as an anthelmintic. He finds that children stand the drug well, and he has given a child of 12 a drachm on two successive days without ill effect. Seventy minims on two successive days is the largest dose he has given an adult. A dose of 60 minims in an old man was followed by irregular pulse and slurring speech. The drug has marked sporicidal properties. It does not appear to aggravate albuminuria and may be given in cases of kala-azar complicated with ankylostomiasis during the remissions of temperature, while kala-azar cases stand chenopodium badly.

The writer finds that carbon tetrachloride is of little value against ascariis, trichurias and hymenolepis. Against oxyurias it appears to be almost specific. Very recently reports from South America state that several cases of acute yellow atrophy of the liver have followed the use of this drug.

[L. D. C.]

CANCER IN THE CERVICAL STUMP; METASTASIS IN THE VERMIFORM APPENDIX.

FRANK (*Surg., Gyn. and Obstet.*, Sept., 1922) writes as follows:

The case reported is one of stump cancer, noticed within five months after supravaginal hysterectomy for fibroids of the uterus. It is, therefore, fair to presume that the carcinoma was overlooked at the time of the operation.

Complete hysterectomy for fibroids of the uterus is not recommended as a routine measure, because of its increased mortality over supravaginal amputation.

Increased care in examining the cervix, before all operations for uterine conditions are undertaken, is enjoined, and it is suggested that the patients after operation be warned to note and report bleeding or abnormal discharge.

A metastasis in the non-adherent appendix is reported as a unique site of secondary deposit from cervical cancer. [E. H. R.]

VOMITING AND DISTENTION AFTER LAPAROTOMY LESS-ENED BY THE SUBSTITUTION OF RUBBER ENVELOPE PADS FOR GAUZE.

BISSELL (*Surg., Gyn. and Obstet.*, Sept., 1922), after a study of some 300-odd cases with controls, concludes that nausea, vomiting and distention are markedly lessened by the use of rubber walling-off pads in the place of gauze, principally because of the lessened amount of trauma to the intestines.

[E. H. R.]

BOVINE TUBERCULOSIS IN INDIA.

LISTON and SOPARKAR (*Ind. Med. Gaz.*, June, 1922) report on an investigation into the nature and origin of an outbreak of tuberculosis among animals in the Bombay Zoological Gardens. They find that the disease, which spread to some 30 animals (deer, hams, antelopes, etc.), was bovine in nature in every case. It probably originated from the hams which were imported from Germany, one of which died of tuberculosis in the gardens. Tuberculosis among cattle is rare in India. [L. D. C.]

THE FUNCTION OF THE GALL-BLADDER IN BILIARY FLOW.

JACOBSON, C., and GYDENES, C. (*Archives of Surgery*, Sept., 1922).—These authors write as follows:

Bile as a secretory product of the liver is produced probably through hormone stimulation associated with the production of acid chyme in the stomach. The height of biliary flow is coincident with the passage of the acid chyme into the duodenum.

There is a marked similarity between the curve of bile production and that of pancreatic secretion.

The smaller continuous secretion of the liver is stored in the gall-bladder, which acts as a reservoir, until evacuated by the demands of digestion. The storage capacity of the gall-bladder is augmented by its remarkable concentrating power.

The S-shaped configuration of the neck and ampulla of the gall-bladder prevents overdistention of the gall-bladder. When overdistended it prevents the exit of bile. By altering the peculiar configuration of the portion of the gall-bladder and cystic duct, inflammatory conditions may readily produce a nonfunctioning gall-bladder.

The sphincter of Oddi, a definite muscle entity at the duodenal end of the common duct, sustains an absolute pressure of about 150 mm. of water. The gall-bladder undoubtedly equalizes the great fluctuations in this pressure due to movements of the abdominal muscles and contiguous organs. Cholecystectomy tends to produce a lowered intraductal pressure and a relaxed tone of the sphincter of Oddi. The sphincter is probably under reflex nervous control associated with the passage of acid chyme into the duodenum and with intrinsic movements of the duodenum itself.

Magnesium sulphate does produce a complete, local relaxation of the duodenal wall and the papillary sphincter, with reduction of the intraductal pressure. Relaxation is transient and is usually accompanied by a flow of bile from the orifice.

There was no evidence that concentrated magnesium sulphate produced any contraction of the gall-bladder or any specific change in the gall-bladder pressure. The augmented biliary flow from its application is probably due to the evacuation of the bile from the bile ducts as a result of sphincter relaxation and also to the stimulating effect of the salt upon the liver secretion.

Flow of bile from the gall-bladder has been produced in certain cases by injection of large amounts of 0.4 per cent. hydrochloric acid into the duodenum. This probably is the mechanism of its discharge at the beginning of digestion.

The production of mucus and the concentrating power of the gall-bladder are suggestive of some purposeful differentiation of that structure, although its removal has been, in human beings, without any definite, clinically demonstrable deleterious effects.

[E. H. R.]

LYMPHO-CYSTIC URETHRAL LESION: AN EVIDENCE OF SYSTEMIC TUBERCULOSIS.

FEIGEL, P. S. (*Journal of Urology*, March, 1922), writes:

Of 16 cases presenting these cysts at autopsy, found by Dr. Randall, all but two showed massive active tuberculosis. In these cases the principal lesions were lungs 94%, kidneys 12%, bladder 12%, intestines 37%, pleura 25%, spleen 25%, liver 12%, S.I. 13% in whom careful clinical studies were possible showed strong evidences of an active tuberculous lesion. In these the lesions were lungs 82%, kidney 14%, epididymis 61%, prostate 8%; in 32% there were tubercle bacilli in the urine.

The urethral lesions are important from a diagnostic standpoint alone as they never ulcerate nor extend to the prostate. They remain as long as the causal focus is active and spontaneously disappear, providing the patient's general health improves. Burning

in some portion of the urethra during micturition is the most common subjective symptom.

These occur in women but are easily confused with the mucosal tabs so common at the female vesical neck.

Many patients have symptoms of prostatitis only and are suspected because treatment fails to improve or makes worse the prostatic condition.

The lesions are only occasionally true tuberculous but are apparently due to the action of some tuberculetoxin. They are never primary urogenital tuberculosis.

From the clinical and autopsy data presented it is felt that the association of these lesions with tuberculosis is too frequent to be coincidental and that every patient in whom they exist has a large or small tuberculous focus that is active.

The paper is concluded by brief histories of the seventy-five cases.

[B. D. W.]

PNEUMOPYELOGRAPHY: A PRELIMINARY REPORT ON ITS ADVANTAGES AND TECHNIQUE.

THOMPSON (*Jour. of Urology*, April, 1922) feels that there is less reaction to injection of oxygen than when opaque solutions are used. He gives a case,—pyelograms and postoperative results. The conclusions arrived at are:

I. Pneumopyelography is a simple, though uncommon, procedure and deserves a greater popularity.

II. Its procedure is attended by apparently no reaction and causes the patient less discomfort than the injection of an opaque solution.

III. In certain cases it is a greater aid in roentgenographic diagnosis than the opaque solutions.

[B. D. W.]

DISSOLUTION OF CALCULI IN THE RENAL PELVIS AND URETER.

BRYAN and CALDWELL (*Journal of Urology*, April, 1922) draw the following conclusions:

I. The means for determining the character of stones can be estimated only by the density of the shadow by x-ray, and by urinalysis, at which time we hope to catch crystals from the stone which may be most misleading.

II. The only stones amenable to dissolution are the phosphatic, which constitute only 9 per cent. of all stones, and the calcium carbonate (very rare), which constitute 4 per cent. of all stones.

III. Stone formation is always attended with the presence of pus. This condition is aggravated by topical applications.

IV. Many stones may be assisted in their expulsion by ureteral dilatation and lubrication.

V. Operation in the upper tract, pyelotomy in the lower tract, by intramuscular gridiron incision, is attended with such happy results that experimentation with solvents would seem impracticable.

VI. The mucosa of the dog, lining the pelvis and the ureter, can stand 0.5 per cent. hydrochloric acid (F. S. P.); stronger than this shows a round-cell infiltration and destruction which in course of time is not followed by repair.

[B. D. W.]

SURGICAL INFECTIONS OF THE KIDNEY.

BAKER (*Journal of Urology*, April, 1922) speaks of the embryology of the portions making up the kidney.

There is difficulty in differentiation because the majority of all kidney infections occur in the female and on the right side. The chief obstacles are:

I. To differentiate it from similar explosions which may occur either in the appendix, gall-bladder, stomach or pancreas.

11. To distinguish it from the more acute pyelitis or pycelonephritis, which may also have a very stormy beginning.

In a series of 75 cases of pyelitis and ureteral stricture, 11 per cent. had been operated upon, during an acute exacerbation, for acute appendicitis. Some of these had operations for chronic appendicitis. All told, 54 per cent. had either been operated upon or had had operation of the abdominal cavity advised as the necessary remedial measure.

Careful study seems necessary of the upper urinary tract before making your abdominal incision.

[B. D. W.]

THE TOXICITY OF POTASSIUM CHLORIDE IN EXPERIMENTAL NEPHRITIS.

UNDERHILL and FERGUSON (*Jour. of Urology*, April, 1922) make the following assertions:

Potassium chloride intravenously administered to rabbits with tartrate nephritis is much more toxic than sodium chloride introduced under similar experimental conditions.

Potassium chloride intravenously injected is no more toxic to rabbits with tartrate nephritis than it is to normal animals.

The induction of a nephritic condition in rabbits by tartrate, therefore, does not render the animal more susceptible to potassium chloride introduced directly into the blood stream.

[B. D. W.]

UNILATERAL FUSED KIDNEYS.

HYMAN (*Jour. of Urology*, April, 1922) declares that this condition is most rare. There is rarely a preoperative diagnosis. One unilateral fused kidney was found at autopsy in over 8000 cases, whereas the horse-shoe kidney is encountered once in 1000 cases. Israel reported two fused and five horse-shoe kidneys in 800 operations.

The two cases reported were diagnosed preoperatively by careful study with opaque catheters in ureters, and pyelograms made. In one a stone in lower portion of fused kidney was removed, with excellent recovery; in the other it was felt that pain was due to pressure and operation would be of no benefit.

[B. D. W.]

SALIGENIN AS A LOCAL ANESTHETIC FOR CYSTOSCOPY IN MEN.

HIRSCHFELDER, WETHALL and THOMAS (*Jour. of Urology*, April, 1922) present these results:

I. In ten cases in which 4 per cent. solutions of saligenin were instilled into the male urethra anesthesia satisfactory for cystoscopy was obtained, as was likewise the case in 20 cases in which 8 per cent. solutions were used.

II. No unpleasant results were experienced in these cases.

III. Saligenin is a local anesthetic of very low toxicity, which can be used satisfactorily for local anesthesia for cystoscopy in the male.

[B. D. W.]

PRESENTATION OF TEST-TUBE HOLDER FOR COLLECTION OF URETERAL SPECIMENS.

LEVY (*Jour. of Urology*, April, 1922) offers the suggestion of using a canvas strap a couple of inches wide, with loops, stretched between the stirrups for holding test-tubes, into which the ureter catheter may be placed while collecting specimens.

[B. D. W.]

A NEW METHOD OF PERINEAL PROSTATECTOMY WHICH INSURES MORE PERFECT FUNCTIONAL RESULTS.

GERAGHTY (*Jour. of Urology*, May, 1922) calls attention to a new procedure in perineal prostatectomies, by which the membranous urethra is avoided and the external sphincter left entirely alone. Thus the occasional functional imperfections obtained by the methods employed now, like lack of control, can be avoided.

A special retractor, devised by Dr. Henry Freiberg, is passed the entire length of the urethra and brings the prostate forward toward the perineum. The prostate is exposed by usual methods and then a curved incision is made through the posterior layer of the prostate, the point of the curve being at the apex of the prostate. The line of cleavage between the capsule and the adenomatous masses is affected by the blunt dissector, and the subsequent dissection, carried out with the finger as is done in the suprapubic enucleation.

Much care in packing must be exercised, especially with regard to the overhanging flap of the bladder wall.

By this method the membranous urethra is not exposed nor at any time in the field of operation. Its intrinsic and extrinsic musculature, as well as the nerve supply, is neither disturbed nor injured.

[B. D. W.]

SPHINCTEROTOMY PER URETHRAM.

GERAGHTY (*Jour. of Urology*, May, 1922) says that contracture of the vesical orifice as a fairly frequent cause of urinary obstruction is now well recognized. It is a fibrosis of varying depth, involving the vesical orifice, particularly in its posterior portion; diminishing sphincteric relaxation, and narrowing the vesical outlet during the act of urination.

When these cases have been opened suprapubically and examined it has been found that simple division of the internal sphincter gave immediate relaxation of the orifice, with complete and permanent relief of obstruction.

The modified Boldini operation of Chetwood and the Young "punch," recently suggested by Caulk, whereby a satisfactory end-result is accomplished, are not infrequently followed by prolonged sloughing and serious hemorrhage.

Dr. Geraghty suggests using a No. 28 E. endoscopic tube, engaging the vesical orifice in the fenestra, and then introducing a wedge-shaped concave knife which accurately fits, thus dividing the fibrotic ring. Urine is usually only blood-tinged, so a retention catheter is not required.

[B. D. W.]

THE STRUCTURAL BASIS FOR CONGENITAL VALVE FORMATION IN THE POSTERIOR URETHRA.

WATSON (*Jour. of Urology*, May, 1922) declares that from the material and evidence at hand it can be stated that the so-called valves or congenital strictures of the prostatic urethra may have their origin as early as the fourteenth week of fetal life, at which time there were present in the specimens studied no associated secondary sequelae such as the dilated posterior urethra, dilated trabeculated bladder with hydronephroses and hydronephrosis, as is usually found in the latter pictures of this condition. The valve formation is due to the growth and attachment of the tip of the colliculus to the roof of the urethra, and occurs at the time of marked epithelial activity of this and associated parts, namely, the invagination of the ventral mucosa to form the first observed tubules of the verumontanum; and of passing interest it may be stated that it occurs also at the time the diverticula of the seminal vesicles

are first noted. The view of Wilkens, that these folds are remnants of the cloacal membrane which are left when the cloaca divides into the sinus urogenitalis, perineum and rectum, cannot be sustained, for at the time this anomaly occurs the above structures are all clearly defined. Also Posner's contention that these folds are the result of faulty union of the pars prostatica and pars membranosa of the urethra seems hardly to be supported. Lowsley's statement seems more nearly correct; that they may be anomalies of the Wolffian and Müllerian ducts; but even this is not entirely adequate. The study of the reported specimens would seem to indicate that these obstructing valves have their origin in the anomalous attachment of the lower portion of the colliculus seminalis and inferior striae to the roof of the urethra.

[R. D. W.]

BONE METASTASIS FROM PRIMARY CARCINOMA OF THE URINARY BLADDER.

WELLS, H. GIDEON (*Journal of Urology*, May, 1922) calls attention to the fact that carcinoma of the urinary bladder, contrary to the prevailing view, not infrequently gives rise to bone metastasis, which may be extensive, even when the bladder tumor is small.

Attention is called to various articles on this subject, showing the lack of bone metastasis or the failure to mention it.

The paper is concluded with a case description in detail, where the complaint was due to large tumor of sternum with no bladder symptoms. A man, sixty-eight, with a typical papillomatous tumor of the urinary bladder which had caused no symptoms of which he complained, developed an enormous secondary growth in the sternum which was completely replaced by tumor tissue. This growth was so large, weighing about the same as a normal human liver, and so symmetrically disposed as to the sternum, that at the autopsy it was believed to be a primary sarcoma of the sternum, the bladder tumor being thought to be merely a coincidental matter; microscopic study, however, showed the tumor of the bone to be derived from the papillary carcinoma of the bladder, as also were the metastatic growths in the ilium, in four ribs, the lung, the kidney and the liver. We can find no record of any other case of bladder carcinoma with a comparable amount of bone metastasis.

[R. D. W.]

A PROCEDURE FOR THE CURE OF PROSTATIC ABSCESS.

BARRINGER, R. S. (*Journal of Urology*, May, 1922) calls attention to fifteen cases of prostatic abscess helped by introducing 1/5 of 1 per cent. novocain and adrenalin with a lumbar puncture needle through the perineum. The anaesthetic is injected ahead of the needle; the needle enters between the urethra and rectum, and then with the index finger in rectum the needle can be plunged into lobes of prostate and pus aspirated.

These 15 cases have been saved general anaesthesia, perineal section damage to the prostatic urethra, and long convalescence by aspirating from the prostate by the needle method; up to date no untoward results have followed this method, and no cases have had to be operated upon subsequent to the aspiration.

Subsequent experience has indicated that the method should be restricted to gonococcal infections; abscesses of the prostate caused by streptococci, staphylococci, or colon bacilli do not do well after aspiration. The method should not be used when the abscess has broken through the capsule of the prostate and is pointing in the ischioanal fossa, or has extended toward the seminal vesicles. Here operation is indicated.

[R. D. W.]

PHYSIOLOGICAL AND PHARMACOLOGICAL STUDIES OF THE PROSTATE GLAND. RESPONSE OF PROSTATIC MUSCLE TO DRUGS.

MAGUIT, D. I. (*Journal of Urology*, May, 1922) reports:

1. The effects of various drugs were studied on strips of surviving excised prostate gland of different animals.

2. The preparations responded promptly with contraction to barium chloride and with relaxation to papaverin hydrochloride, thus indicating the presence of muscle tissue.

3. The preparations responded distinctly to treatment with epinephrin and ergotoxin, but failed to respond (with the exception of the rabbit's prostate) to treatment with pilocarpin, physostigmin, muscarin, and atropin.

4. These observations speak in favor of a true sympathetic innervation of the prostate gland.

[R. D. W.]

FURTHER NOTES ON DISEASES OF THE UMBILICUS.

CULLEN (*Surg., Gyn. and Obstet.*, Sept., 1922) contributes one of his characteristically thorough, complete, and beautifully illustrated articles. He describes many bizarre conditions found at the umbilicus, all with most excellent photographs and drawings. Among these, he describes cases of tetanus in the new-born due to careless treatment of the umbilical stump, various forms of granuloma of the umbilicus, polyps, Meckel's diverticulum found in the umbilicus, cysts, adeno-myoma, naevus, moles, papilloma, various forms of carcinoma, and various forms of hernia. The article is most interesting and instructive.

[E. H. R.]

COMBINED TRANSPLEURAL AND TRANSPERTONEAL RESECTION OF THE THORACIC ESOPHAGUS AND THE CARDIA FOR CARCINOMA.

HEBROM (*Surg., Gyn. and Obstet.*, Sept., 1922) reports a most interesting case in which the above operation was done for carcinoma involving the esophagus and upper portion of the stomach. The operation followed a preliminary resection of the fifth to eleventh ribs and was performed under local anaesthesia and gas oxygen. The left pleural cavity and the left peritoneal cavity were opened widely, the diaphragm was split to the hiatus, the esophageal stump was sutured to the skin edges in the middle axillary line, and the gastric stump was brought to the surface near this line. The patient recovered from the operation and is able to take food by mouth through a tube connecting the two stomata. The case is reported in detail and illustrated with photographs.

[E. H. R.]

INFECTION IN THE MEDIASTINUM IN FULMINANT CASES OF EMPYEMA.

DUNHAM (*Surg., Gyn. and Obstet.*, Sept., 1922) presents a very interesting article based on the large number of cases seen during the World War, and as a result of his study, together with the study of the pathological material taken at autopsy, he concludes that, in the fulminating type of empyema, infection of the mediastinum is one of the most fatal complications. This infection is most likely to occur before the defensive reactions of the body are adequate to ward it off, and this type of infection is the immediate cause of death in these cases.

[E. H. R.]

THE BOSTON Medical and Surgical Journal

Established in 1828

Published by The Massachusetts Medical Society under the jurisdiction of the following-named committee:

For three years WILLIAM H. ROBERT, JR., M.D.

ROGER I. LAE, M.D.

ROBERT B. OSGOOD, M.D.

For two years JAMES S. STONE, M.D.

HORACE D. ARNOLD, M.D.

CHANNING FROTHINGHAM, M.D.

For one year HOMER GAGE, M.D., *Chairman*.

EDWARD C. STREETER, M.D.

EDWARD W. TATTLER, M.D.

EDITORIAL STAFF.

DAVID L. EDGALL, M.D.

GEORGE G. SMITH, M.D., *Assistant Editor*.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.56 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

THE ANNUAL MEETING OF THE NEW ENGLAND SURGICAL SOCIETY.

This meeting was held in Burlington, Vermont, September 22 and 23. About sixty per cent. of the members and several invited guests were present. The weather was ideal and the social features provided by the Vermont members added very much to the enjoyment of those in attendance. A few of the members who traveled by automobile arranged for side trips, in order to enjoy the beauties of the Green Mountains and Lake Champlain. The scientific program was varied. The importance and the manner of presentation of the subjects held the attention of the audience throughout the sessions.

Five papers relating to urological subjects were presented, covering the advances in treating complications of prostate gland surgery, and the importance of pyelography, both in dealing with abnormalities of the ureter and kidney, and also in elucidating obscure conditions met by the general surgeon. Two papers devoted to the surgery of childhood under the titles of "Hare Lip" and "Tuberculous Adenitis" brought out the technic of appropriate operations, and in the latter subject the rules for operative or other treatment, as the cases might require. Under gynecology, the advantage of the operation that makes use of the combined method of shortening of the round ligaments by means of fixation in

the upper anterior part of body of the uterus, and the attachment of the bladder high up on this organ was advocated in suitable cases, and the problems presented by cancer of the cervix were presented. In this latter condition the records of the Massachusetts General Hospital were used to demonstrate the frequency of failure to recognize cancer at the time of a supravaginal hysterectomy, as well as the danger of the development at any later period in the cervical stump. Under anesthesia, the advantage of local over general anesthesia in strangulated hernia was endorsed, although statistics, in some instances, might lead to incorrect conclusions because of failure to study other important factors. A paper on the results of anesthesia in a service, brought out the advantages of careful administration and oversight, and the resulting benefits to the patients.

There were two papers dealing with diverticulum of the oesophagus. The advantages of the two-stage operation and improved technic were explained, and it was shown that under modern methods, as applied to suitable cases, the prospect of good results is much better than secured in former times. The papers on "Myeloma of the Vertebrae," and "Myoma of the Stomach" presented the pathology of these conditions, in addition to the report of interesting cases. The paper by Dr. Eugene Pool of New York, on "Injuries to the Spleen," brought out the difficulties of diagnosis, and the dangers which are increased by delayed treatment in these cases. The remaining papers under the following titles, "Myositis Ossificans," "Enteroliths," "Arterio-mesenteric Obstruction of the Duodenum," "Postoperative Intra-abdominal Adhesions," "Surgery in Diabetes," and "Postoperative Swelling of the Upper Extremity Following Operations on the Breast and Axilla" all brought out animated discussions.

The attempt of the reader of the paper entitled "Hernia from the Employer's Standpoint," to get the Society to take a position on the status of hernia in industrial insurance was not endorsed at this meeting, but a committee was appointed to consider the subject and make a report.

These brief references should lead to the careful perusal of the papers as they will appear in this JOURNAL from time to time.

The only criticism that could be made of the meeting consists in reference to the wealth of material presented, for although the President exhibited energy and control, it was well-nigh impossible to keep strictly to the time specified in the program or to give sufficient time to the discussions following the reading of papers.

The dinner, which was served on the boat on the return trip from Plattsburg, was most enjoyable for its social and gastronomic features. One especially delightful incident was the resuscitation of Dr. Francis S. Watson, who had officially died, according to the records of the Sec-

retary. Dr. Watson evidently enjoyed his return to life, and entertained the Society and guests by anecdotes and reports of his travels abroad. His warning of the great peril to civilization existing in the unsettled and complicated affairs of Europe and Asia was impressive.

Considerable interest was shown in the proposal to have a joint meeting or series of meetings of the several New England medical societies for the purpose of uniting the profession of New England in all questions relating to professional policies and the dissemination of information relating to progress in medicine. Definite action, however, may be taken only after further consideration and a study of a similar plan now being agitated in the American Medical Association.

The officers elected for the ensuing year are as follows:

President—Dr. John F. Thompson, of Portland.

Vice-president—Dr. Lyman Allen, of Burlington.

Secretary—Dr. Philemon E. Truesdale, of Fall River.

Treasurer—Dr. Peer P. Johnson, of Beverly.

The President's address will be published in a later issue of the JOURNAL.

Dr. Thomas Kittredge of Salem, Mass., and Dr. William F. Hazeltin of Bellows Falls, Vt., were elected as Honorary Members and the following-named surgeons to active membership:

Dr. Stephen Rushmore, Boston.

Dr. James Walker Jameson, Concord, N. H.

Dr. Samuel Clark Harvey, New Haven, Conn.

Dr. Alvan Davidson, St. Albans, Vt.

Dr. Robert Carlyle Cochrane, Boston.

GROUP INSURANCE.

It will be remembered that the Council of the Massachusetts Medical Society, after careful study of the indemnity insurance offered to physicians, recommended group insurance to its members. By this plan members of the Society may take out insurance at a rate which is the same to each policy holder. About eleven hundred members have adopted this form of insurance.

Another company than the one recommended by the Society is offering insurance on a graded plan according to the nature of the work done by physicians, ranging in price from eighteen to seventy-five dollars for a five to fifteen thousand dollar policy.

So far as our members choose different forms of insurance, the plan advocated by the Council is weakened. The policy of the company recommended by the Council (The United States Fidelity and Casualty Co.) is to contest every suit brought against its policy holders, so as to discourage the custom of some attorneys of attempting to influence physicians and insurance

companies to settle doubtful or unjust claims. It is less expensive, in many instances, to compromise rather than defend a suit, but the adoption of this policy of compromise encourages the instigation of unworthy suits. Since the expense of defense is oftentimes greater than that of compromise, an insurance company cannot carry through the policy of general defense unless there is a large number of policy holders, and it is estimated that the minimum number in a group should not be less than two thousand. It is confidently expected that if over two thousand of our members unite in this group and pursue the plan of contesting every suit, the number of suits will diminish, and after a time the company will be able to furnish the insurance at a figure of eighteen dollars or less.

The question really is whether we will stand together and adopt a plan which will be for the greater benefit of the profession, or whether a sufficient number may be induced to take on classified insurance in one class a little lower than that in the group plan.

Another company has attacked the group plan, and made the point that the testimony of one physician in a group in favor of another in the same group would react unfavorably. Eminent legal opinion has been submitted to the effect that evidence of membership in a group would not be admitted in a trial. This latter company cannot do business in this state except by correspondence, as shown by the following letter:

State House, Boston, August 7, 1922.

O'Neil & Parker, Managers.

United States Fidelity and Guaranty Company,
43 Kilby Street, Boston, Mass.

Attention Mr. John E. O'Neil.

Gentlemen:—

The company about which you inquire is not authorized to do business in this Commonwealth. Its resident policyholders would not be able to bring suit against the company in our courts.

The situation is the same in regard to this company as it is with any unadmitted company, whether doing fire, accident, compensation, liability or any other line of insurance.

Very truly yours,

ARTHUR E. LINNELL,

First Deputy Commissioner.

NEWS ITEMS.

WEEK'S DEATH RATE IN BOSTON.—During the week ending September 23, 1922, the number of deaths reported was 197, against 191 last year, with a rate of 13.41. There were 38 deaths under one year of age, against 26 last year.

The number of cases of principal reportable diseases were: Diphtheria, 42; scarlet fever,

16; measles, 15; whooping-cough, 60; typhoid fever, 12; tuberculosis, 28. Included in the above were the following cases of non-residents: Diphtheria, 7; scarlet fever, 2; typhoid fever, 3; tuberculosis, 3.

Total deaths from these diseases were: Diphtheria, 2; whooping-cough, 4; typhoid fever, 2; tuberculosis, 9. Included in the above were the following cases of non-residents: Diphtheria, 2; typhoid fever, 1.

REMOVAL.—Dr. Theodore L. Story has moved from his former office on Commonwealth Avenue to 141 Sutherland Road, Brighton.

Miscellany.

LEGISLATIVE MATTERS.

MASSACHUSETTS CONTESTS THE FEDERAL MATERNITY AND INFANCY ACT.

The Commonwealth of Massachusetts has, by its Attorney General, petitioned the U. S. Supreme Court for leave to file a bill of complaint in a suit between the State and certain government officials, in order to enjoin them from enforcing the act for the promotion of the welfare and hygiene of maternity and infancy, known as the Sheppard-Towner Act. The defendants named are Andrew W. Mellon, Secretary of the Treasury; Grace Abbott, Chief of the Children's Bureau of the Department of Labor; Charles E. Sawyer, Surgeon General of the Public Health Service; John J. Tigert, Commissioner of Education. Incidentally, Charles E. Sawyer is not the Surgeon General of the Public Health Service and the inclusion of his name as such is an error.

The original bill of complaint, for which permission is asked to file, sets forth the following items:

(1) That three of the defendants constitute the Federal Board of Maternity and Infant Hygiene. No reason is given for joining the Secretary of the Treasury.

(2) That the suit is instituted pursuant to an order of the State Legislature for the purpose of restraining defendants from carrying out the Act.

(3) That Congress unlawfully assumed a power not delegated to it, but reserved to the States by the Tenth Amendment to the Constitution, when it passed this Act. The provisions of the law are then set out in detail. The argument is advanced that appropriations made under the act are for local and not national purposes, that the burden of paying for it falls unequally on the States, and that the sovereign power of the plaintiff is usurped. Action already taken under the law by the Children's Bureau is also set forth.

The petition, which was filed on September 8,

1922, will be considered at the October term of the U. S. Supreme Court, which begins on October 2, 1922.—*Bulletin of the National Health Council.*

RESOLUTIONS.

The National Health Council reports that a resolution has been introduced in the House by Representative Ryan requesting the President to remove Brigadier General C. E. Sawyer, as chief of the coordination section of the Veterans' Bureau, and to fill the position with someone of professional standing, capable of discharging the government's obligation to disabled soldiers. In its resolution it is stated that General Sawyer has claimed that his duty as physician to the President interferes with the responsibilities of this position.

Senator King has introduced a resolution asking for the appointment of a committee to investigate the U. S. Veterans Bureau, with especial reference to the following matters:

(a) Alleged lassitude and delay in the administration of the Veterans' Bureau and in the making of adjustments for compensation and payments.

(b) Rules and regulations promulgated by the Bureau and its organization are so complicated and over-elaborated as to cause intolerable indirection in handling cases.

(c) Great and needless delay in the construction of hospitals and in providing proper hospitalization for relief of disabled war veterans.

(d) Large proportion of appropriations made by Congress is being consumed in overhead expenses instead of being used for the relief of disabled soldiers.

(e) Popular feeling exists all over the country that acts of Congress in behalf of the veterans are not being properly and equitably administered.

The President has recommended the reappointment of Major General M. W. Ireland.

FEATURES OF THE TARIFF BILL.

The report of the conference fixing, among other articles, a 60 per cent. rate on medicinals with a specific duty of 7 cents per pound, if passed, is expected to kill the chemical industry in this country. A duty of 45 per cent. on surgical instruments has been agreed to by the conferees.

REPORT OF THE WORCESTER CITY HOSPITAL.

FOR THE YEAR ENDING NOV. 30, 1921.

The arrangement of the statistics showing the work done in this institution is admirable, for

the facts are presented in available form for comparison with other hospitals of this class.

A summary of this year's work is as follows:

Six thousand, three hundred and twenty-eight (6,328) bed patients were given 104,498 days' treatment at an expense of \$411,107.47.

Thirty-one thousand, three hundred and forty-two (31,432) treatments were given in the out-patient department at an expense of \$22,795.49, or \$7.27 per treatment.

One thousand and sixty-five (1,065) were treated in the accident room at an expense of \$4,187.42, or \$3.93 per patient.

There was a total of 104,498 days' treatment in the hospital proper, 31,342 treatments in the out-patient department and 1,065 treatments in the accident room at a total expenditure of \$438,090.38.

The average expenditure for each bed occupied continuously throughout the year was \$1,435.98, as against \$1,506.45 in 1920. This does not include the expenses of the out-patient department, or of the accident room, nor does it include interest on investment or depreciation of plant.

RECEIPTS.

Balance on hand November 30, 1920....	\$7,433.09
Appropriation from tax levy.....	200,000.75
Income from patients and sales.....	156,535.22
Income from funds.....	16,970.90
	\$440,939.96

EXPENDITURES.

General fund.....	\$432,669.77	
Special funds.....	3,822.15	436,491.92
General fund balance.....	501.31	
Special fund balance.....	3,946.73	
		\$4,448.04

PER CAPITA COST.

The average cost of caring for patients has been \$27.54 per week, as against \$28.89 in 1920.

STATISTICS.

There were admitted to the surgical wards, 2,051 patients, compared with 1,758 last year. The daily average cost of surgical patients was \$4.02, compared with \$4.13 last year.

There were 1,355 patients admitted to the medical wards, compared with 1,386 in 1920. The daily cost of medical patients was \$4.12, compared with \$4.09 in 1920.

The number of children admitted was 642, compared with 707 in 1920. The daily average cost of children was \$4.02, as against \$4.43 in 1920.

There were 1,065 minor accidents treated at a total expense of \$4,187.42, or \$3.93 per treatment, compared with \$4.04 last year.

The number of patients admitted to the maternity service was 655 compared with 583 last

year. There were 630 births, as against 539 in 1920. The daily average cost of this department, including infants as patients, was \$2.95, compared with \$3.35 in 1920.

The average number of beds occupied during the year was 286.29, while the average last year was 255.5.

The average duration of residence in the hospital of free and paying patients was 16.50, compared with 16.31 last year. The number of days' treatment was 104,498, as against 93,257 the year previous.

The largest number in the hospital in any one day was 344, compared with 306 last year; and the smallest number was 229, compared with 220 in 1920.

OUT-PATIENT DEPARTMENT.

There were admitted to the department 6,962 new patients, compared with 4,431 in 1920. They were divided among the different clinics as follows: Medical, 1,435; surgical, 1,529; eye, 687; ear, nose and throat, 1,273; dermatological, 313; gynecological, 166; neurological, 27; orthopedic, 458; genito-urinary, 453; lung, 125; massage, 75; electro-therapeutic, 71; dental, 174; prenatal, 151.

Last year there were 4,431 patients admitted to all clinics, an increase this year of 2,531. The total number of visits this year was 31,342, as compared with 19,636, an increase of 11,706.

The visits among the different divisions were divided as follows: Medical, 3,908; surgical, 9,791; eye, 2,033; ear, nose and throat, 3,093; dermatological, 720; gynecological, 709; neurological, 72; orthopedic, 1,539; genito-urinary, 6,379; lung, 441; massage, 540; electro-therapeutic, 1,387; dental, 355; prenatal, 356.

The daily average treated was 103.1, as compared with 65.02 in 1920.

THE TUBERCULOSIS INSTITUTE.

THE Boston Tuberculosis Association will hold the second Institute for Physicians on Thursday and Friday of this week. The program of the first day and the morning of the second day will be given in the amphitheater of the Massachusetts General Hospital. The afternoon of the second day will be spent at the North Reading State Sanatorium. A complimentary luncheon will be served to those in attendance, and transportation to North Reading has been arranged for those who have applied to Dr. Cleveland Floyd. These meetings are of the greatest interest to all concerned in the problems of tuberculosis. The success of last year's Institute warrants expectation of a successful series of meetings.

The program is as follows:

BOSTON TUBERCULOSIS ASSOCIATION.

INSTITUTE FOR PHYSICIANS.

Thursday Morning, October 5, 1922—Dr. Cleveland Floyd Presiding.

10-11—"Problems in Tuberculosis from the General Practitioner's Point of View," by Dr. Allen K. Krause, Professor of Medicine, Johns Hopkins Hospital, Baltimore, Md.

11-11:30—"Tuberculosis from the Standpoint of the Pathologist," by Dr. George Magrath, Medical Examiner, Suffolk County.

11:30-12—"Laboratory Aids in the Diagnosis of Tuberculosis," by Dr. Cleveland Floyd, Director, Out-Patient Clinic, Boston Sanatorium, Boston, Mass.

12-12:30—"Function of Boards of Health in Relation to Tuberculosis," by Dr. Francis X. Mahoney, City Health Commissioner, Boston, Mass.

12:30-1—"Treatment of Tuberculosis in the State Sanatoria" (with lantern slides), by Dr. Sumner Remick, Director, Division of Tuberculosis, Department of Public Health, Boston, Mass.

Luncheon.

Thursday Afternoon, October 5, 1922—Dr. John B. Hawes, 2nd, Presiding.

2-3—"Coördination of Clinical Pathological Findings in Tuberculosis," by Dr. William H. Smith, Visiting Physician, Massachusetts General Hospital, Boston, Mass.; Dr. Oscar Richardson, Pathologist, Massachusetts General Hospital, Boston, Mass.

3-4—"Correlation of Clinical Findings and X-Ray in Cases of Tuberculosis," by Dr. John B. Hawes, 2nd, Director of Clinic of Pulmonary Diseases, Massachusetts General Hospital, and President, Boston Tuberculosis Association; Dr. George W. Holmes, Roentgenologist, Massachusetts General Hospital, Boston, Mass.

Friday Morning, October 6, 1922—Dr. Cleveland Floyd Presiding.

10-10:45—"Diagnosis of Tuberculosis," by Dr. H. R. M. Landis, Physician-in-Chief, Phipps Institute, Philadelphia, Penn.

10:45-11:15—"Physician and Patient," by Dr. Richard Cabot, Professor of Medicine, Harvard University.

11:15-11:35—"Function of the Preventorium in Relation to Tuberculosis in Children," by Dr. Randall Clifford, Examining Physician, Prendergast Preventorium.

Afternoon session at the North Reading State Sanatorium in cooperation with the State Department of Public Health.

Luncheon at North Reading State Sanatorium, leaving Massachusetts General Hospital at 11:35 by automobile.

Friday Afternoon, October 6, 1922—Dr. Eugene R. Kelley Presiding.

1-1:30—"Symptomatic Treatment of Tuberculosis," by Dr. Edward O. Otis, Professor, Tufts College Medical School, Boston, and President, Massachusetts Tuberculosis League.

1:30-2—Luncheon.

2-5—Clinic conducted by Dr. Sumner Remick, Director, Division of Tuberculosis, Department of Public Health, Boston; Dr. Carl C. McCorsion, Superintendent, North Reading State Sanatorium; Dr. Earl C. Willoughby, Assistant Superintendent, North Reading State Sanatorium; Dr. Joseph W. Reddy, Assistant Physician, North Reading State Sanatorium; Dr. P. Challis Bartlett, Medical Examiner and Consultant, the Community Health and Tuberculosis Demonstration, Framingham, Mass.; Dr. John B. Hawes, 2nd, Director of Clinic of Pulmonary Dis-

eases, Massachusetts General Hospital, Boston; Dr. Frank H. Hunt, Resident Medical Officer, Boston Sanatorium, Mattapan; Dr. Bradford Kent, Examiner; Out-Patient Department, Boston Sanatorium; Dr. Frederick T. Lord, Instructor, Harvard Medical School; Dr. Edward O. Otis, Professor, Tufts College Medical School, Boston; Dr. Joseph H. Pratt, Boston.

AS OTHERS SEE US

A DELEGATION from the Municipal Tuberculosis Sanatorium of Chicago recently visited the Forsyth Dental Infirmary. In making the report, after giving details of the founding and operation of the Forsyth Infirmary, the following language is used:

"We, of Chicago, may be pardoned if we are proud and boastful of our splendid tuberculosis organization and of our general health record. Our investigations and observations during our recent visit convinced us that we have every right to be. In no city of the East, and that of course means no city in the country, have they the efficient, effective plan for the fighting of tuberculosis that we are fortunate enough to have in operation.

"Our hats are off to Boston," at the same time warning the 'Hub of the Universe' to 'look to her laurels,' for our coats are off, too, and our sleeves rolled up (metaphorically speaking). We are going to work to get for the little ones of Chicago what the noble-hearted Forsyth men gave to the little ones of Boston, and our plans are already well under way."

It may be that we have overestimated the work of the Boston Tuberculosis and the state organizations. Since the challenge has been published it is in order to send a committee to Chicago and ascertain the relative efficiency of organizations in the Middle West as compared with those in our Eastern cities.

PHYSICIANS IN THE UNITED KINGDOM.

THE *Medical Press and Circular* reports that statistics show that there are nearly forty-six thousand doctors in the United Kingdom, with a population of forty-six million. This makes a proportion of one doctor to a thousand people. There has been a gradual change in this proportion, for in 1881 it was one to fifteen hundred.

Sir Clifford Allbutt, speaking of financial considerations in relation to medicine, says:

The average cost of becoming qualified as a medical practitioner is estimated at £1,500, and this does not take account of what might be earned during this period over and above that expended on maintenance.

Fortunes are not easily made in the medical profession.

"Anyone who enters our profession with the sole object of making a fortune has, of course,

mistaken his calling . . . the main reward of the medical life is the knowledge of good work done."

And the editor of *The Medical Press and Circular* gives this advice to medical students:

I venture to emphasize the advice I have given on a former occasion as to the importance to the student of good health. The sounder the health, the sharper the wits, the more retentive the memory, and the more congenial the work.

Let, then, the student keep as physically fit as possible; by observing regular hours, by carefully regulating his meals, and not hurrying over them, by not over-smoking, and by taking a due amount of physical exercise.

Every student should have his eyes tested as a matter of routine, and wear suitable lenses if these are considered necessary, for even a small error of refraction may greatly impair the capacity for sustained reading.

Equally important is the need to take care of the teeth. The British have the worst teeth in the world, and the future doctor may do much to remedy this evil. He should be able in his own person to prove to his patients that it is possible to retain a sound set of teeth into advanced age.

Let me also impress upon the student not to get into the habit of looking upon the time he spends at his medical studies as so many years of drudgery which have to be got through before the promised land is reached. Rather should he regard them as the best and happiest years of his life (as, in point of fact they probably will turn out to be), and seek to get all the legitimate enjoyment he can out of them.

The method of work is also all-important. The student may do much to lighten his work by concentrating on the essential. It is better to get up the important things thoroughly than to burden the mind with a mass of detail, most of which will probably soon be forgotten. For this reason I advise the student not to neglect the use of small books.

Trust as far as possible to visual memory in learning such a subject as anatomy.

Don't work when you feel tired, and don't work late into the night.

Never miss a coaching class, or college examination. If you have an opportunity of coaching a willing student on a subject you know better than he, do not neglect it; for the teacher often derives more good from his teaching than his pupils. In this way he tests and consolidates his knowledge.

It is a good plan to write a three hours' examination paper at least once a week, after having read up the questions beforehand. In this way facility in expressing the thoughts accurately in writing will be acquired. Many fail in examinations because they are lacking in this respect.

Medical students in this country could read and apply this advice to advantage.

Obituary.

HORATIO ROBINSON STORER, M.D.

DR. HORATIO R. STORER, a noted figure in gynecology and medical jurisprudence in the Boston of fifty years ago, has died at his home in Newport, Rhode Island, at the advanced age of ninety-two years. Although something of an invalid for many years, the end came on September 18, 1922, after an illness of six months. Dr. Storer was the son of David Humphreys Storer, eminent obstetrician and naturalist of Boston, and Abby Jane Brewer, a descendant of Governor Dudley of the Massachusetts Bay Colony. He was born February 27, 1830, was graduated from Harvard College in 1850, where he was a private pupil of Louis Agassiz and Asa Gray, then turning his attention to medicine he received the degree of M.D. from Harvard in 1853. The following two years were spent in study in Paris, London, and Edinburgh, in the last city serving as private assistant to Sir James Y. Simpson, the introducer of chloroform. In 1855 he established himself in Boston and made a specialty of gynecology, a new department of medical practice, while assisting his father, who lectured at Harvard. In 1865 he was chosen to the chair of obstetrics and medical jurisprudence in the Berkshire Medical Institution at Pittsfield, a position he held nominally for four years, though the college closed its doors officially in 1867. To better fit himself for teaching medical jurisprudence Dr. Storer attended the Harvard Law School, taking the degree of LL.B. in 1868. For several years he delivered in Boston a semi-annual course of lectures upon the surgical diseases of women that was very popular among graduates in medicine from all parts of the country. He was visiting physician to the Boston Lying-in Hospital, to St. Elizabeth's Hospital, and to St. Joseph's Home, visiting surgeon to the New England Hospital for Women and Children, and consulting surgeon to the Carney Hospital.

Dr. Storer was one of the founders and at one time president of the "Boston Gynecological Society," established on lines similar to the "Obstetrical Society of Boston" (1861). He edited: "Obstetric Memoirs and Contributions of Professor (Sir) James Y. Simpson of Edinburgh (with Dr. Sir William O. Priestly of London)" 1855; he was the author of "Criminal Abortion in America," 1859; "Criminal Abortion, Its Nature, Its Evidence and Its Law" (with F. F. Heard); "Why Not?—a Book for Every Woman," 1865; "Is it I?—a Book for Every Man," 1869; "On Nurses and Nursing, with Special Reference to the Management of Sick Women," 1868. He edited the journal of the Boston Gynecological Society from 1869 to 1873 and in 1871 he was president of the Association of American Medical Editors, and by special invitation of the California state

board of health in that year delivered a lecture in Sacramento, California, on "Female Hygiene."

In 1872 Dr. Storer's health failed and he went abroad, spending most of the time during the next five years in Italy, where he wrote "Southern Italy as a Health Station for Invalids," 1875. On his return he established his residence in Newport, R. I., where he lived until his death, taking an absorbing interest in civic affairs, founding a natural history society and gathering a remarkable collection of medical medals, begun in 1878, soon after his return from abroad, and presented to the Boston Medical Library in 1900, to be known as the "Storer Memorial Collection of Medical Medals," in memory of David Humphreys Storer, his father, and cared for as curator by his son, Dr. Malcolm Storer of Boston. The collection has been enriched yearly by gifts of the donor and others and is now considered by numismatists the largest of all special collections, both in numbers and in the breadth of the field covered.

On his ninety-first birthday Dr. Storer was presented with a loving cup by citizens of Newport for aid to the public health for nearly fifty years. Fordham (N. Y.) gave him her LL.D. in 1912, and in 1918 he received the gold Liberty Service medal of the National Institute of Social Sciences for his work in aiding control of pestilence among soldiers and sailors of the United States.

Dr. Storer married Emily Alvira Gilmore, who died some years ago. He is survived by three sons and a daughter: John H. Storer, of Waltham; Dr. Malcolm Storer, of Boston; Frank Storer, of Miami, Fla.; and Miss Agnes Storer, of Newport.

Correspondence.

PAUL H. DE KRUIF.

Mr. Editor:

In the BOSTON MEDICAL AND SURGICAL JOURNAL for September 14, page 424, a brief item appears under the title "Exposure of the Proprietary Medicine Industry," relative to Paul H. De Kruijf, the author of a series of articles now running in *Heart's International*. In this item is published a letter signed "American Medical Association," giving what purports to be all the information on file at this office concerning Paul H. De Kruijf. The letter, in fact, fails to give a good deal of information that is on file in this office.

Your inquiry, to which the letter referred to was an answer, was referred to Dr. Craig, whose untimely death occurred recently. Dr. Craig was, at the time of the receipt of the letter, on his vacation, and, in his absence, it was answered by his secretary, who, unfortunately, did not go beyond the biographical information in our files relative to medical students.

It is unfortunate that the prefix "Dr." is used before De Kruijf's name in the "Doctors and Drug Mongers" series now appearing in *Heart's International*, because it is bound to lead to a misapprehension. Dr. Paul H. De Kruijf is not a graduate in medicine, although, as stated in the previous letter,

he attended the University of Michigan Medical School for three sessions. He was, however, graduated by the University of Michigan, and from this same institution also received his doctorate degree in philosophy.

Dr. De Kruijf, after graduation, did good work with Novy on anaphylaxis and anaphylotoxin. Later he was appointed associate in the Rockefeller Institute for Medical Research. There, in conjunction with Jacques Loeb and others, he has done important work on bacterial mutations and on the physical properties of bacteria. Among his contributions to scientific literature are:

"Experimental Research on Effect of Intravenous Injection of Gum Salt Solutions"—*Ann. of Surg.*, lxxix, 297, March, 1919.

"Dissociation of Microbic Species"—*J. A. M. A.*, lxxvi, 651, March 5, 1921.

"Dissociation of Microbic Species, Coexistence of Individuals of Different Degrees of Virulence in Cultures of Bacillus of Rabbit Septicemia"—*J. Exper. Med.*, xxxiii, 773, June, 1921.

"Change of Acid Agglutination Optimum as Index of Bacterial Mutation"—*J. Gen. Physiol.*, iv, 387-393, March, 1922.

"Mechanism of Granular Growth of Rabbit Septicemia Bacillus Type G"—*J. Gen. Physiol.*, iv, 395-402, March, 1922.

"Mutation of Bacillus of Rabbit Septicemia"—*J. Exper. Med.*, xxxv, 561-574, April, 1922.

"Virulence and Mutation of Bacillus of Rabbit Septicemia"—*J. Exper. Med.*, xxxv, 621-623, May, 1922.

Also, in conjunction with P. M. Ireland, "Streptolysin"—*J. Infect. Dis.*, xxvi, 285, April, 1920.

Very sincerely yours,

THE JOURNAL A. M. A.,

ARTHUR J. CRAMP,

Propaganda Department.

BRISTOL NORTH DISTRICT MEDICAL SOCIETY.

Mr. Editor:

On September 21, 1922, there was a meeting of the Bristol North District Medical Society. A committee was appointed to communicate with the Bristol South and the Plymouth districts for the purpose of arranging a joint meeting at the Lakeville Tuberculosis Sanatorium some time in November. The paper of the evening was read by Dr. Dunbar of the laboratory of Tufts College on the relations between the laboratory worker and the general practitioner. This was followed by an animated discussion.

Yours sincerely,

JOSEPH L. MURPHY,
District Reporter.

NOTICES.

THE ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

"The Association of Military Surgeons of the United States will hold its 31st annual meeting in the auditorium of the Interior Department Building, Washington, D. C., beginning October 12, at 9:30 A. M. An interesting literary and professional program is in prospect, and the association will have as distinguished guests delegates from the British naval service, from Canada and from Spain. The officers of the association for this year are Captain F. L. Plowell, M.C., U. S. Navy, President; Colonel Charles Lynch, M.C., U. S. Army, first vice-president; Colonel David S. Fairchild, Jr., M.C., Iowa N. G., second vice-president; Senior Surgeon J. C. Perry, U. S. P. H. S., third vice-president; and Colonel James Robb Church, U. S. A. (Ret.), Washington, D. C., secretary-treasurer."

AN IMPORTANT MEETING.

On the evening of October 18, Dr. John O. Polak, Professor of Obstetrics and Gynecology in the Long Island College Hospital, will speak at the Boston Medical Library on Cesarean Section. The meeting will be the first of those to be held by the Suffolk District this season, but at all the meetings physicians interested who are not members of the Suffolk District will be welcomed.

UNITED STATES CIVIL SERVICE EXAMINATION.

LABORATORY AID IN BACTERIOLOGY.

November 8, 1922.

The United States Civil Service Commission announces an open competitive examination for laboratory aid in bacteriology on November 8, 1922.

Applicants should at once apply for Form 1312, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C., or to the secretary of the United States Civil Service Board. Applications should be properly executed, excluding the medical certificate, and filed with the Commission at Washington in time to arrange for the examination of the applicant.

The second annual meeting of the American Association of Oral and Plastic Surgeons will be held in Boston at the Boston Medical Library, Friday and Saturday, October 20 and 21. An interesting program has been arranged, and those interested in this field of surgery are cordially invited to be present.

MASSACHUSETTS STATE NURSES' ASSOCIATION.

The autumn meeting will be held Saturday, October 7, 1922, at American Legion Hall, Gloucester, Mass. An interesting program has been arranged under four sections: League of Nursing Education, Private Duty Nurses, Public Health Nurses, and Massachusetts State Nursing Association. Congressman A. Platt Andrews will address one of the section meetings.

DISEASES REPORTED TO THE MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH.

WEEK ENDING SEPTEMBER 23, 1922.

<i>Disease.</i>	<i>Cases.</i>	<i>Disease.</i>	<i>Cases.</i>
Anterior poliomyelitis	12	Ophthalmia neonatorum	25
Chicken-pox	14	Pneumonia, lobar	18
Diphtheria	139	Scarlet fever	62
Dog bite requiring antirabic treatment	3	Syphilis	38
Encephalitis lethargica	2	Suppurative conjunctivitis	6
German measles	3	Trachoma	3
Gonorrhea	88	Tuberculosis, pulmonary	112
Influenza	5	Tuberculosis, other	21
Malaria	1	forms	32
Measles	58	Typhoid fever	32
Mumps	32	Whooping-cough	141
		Hookworm	1

BOOKS RECEIVED.

The JOURNAL acknowledges the receipt of the following books for review:

Principles and Practice of X-Ray Technique for Diagnosis. By John A. Metzger. Published by C. V. Mosby Co., St. Louis, 144 pages. Price \$2.75.

Diseases of Skin. Second edition. By Henry H. Huxen. Published by C. V. Mosby Co., St. Louis, 608 pages. Price \$7.50.

Atlas of Syphilis. By Professor Leo V. Zambusch. Published by William Wood & Co., New York 31 plates. Price \$15.

SOCIETY MEETINGS.

DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed as information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District:—Hyannis, November 3, 1922, February 2, 1923, (Annual Meeting)—May 4, 1923.

Bristol North, Bristol South, Barnstable and Plymouth Districts will hold joint meetings sometime this fall.

Bristol South District:—Fall River, November 2, 1922, May 3, 1923.

Eastern Hampden Medical Association:—Springfield, October 5, 1922.

Essex North District:—Haverhill, (Semi-Annual Meeting)—Jan. 3, 1923. Y. M. C. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Essex North, Essex South, Middlesex North and Middlesex South Districts will hold joint meetings October 18. Place undecided.

Hampden Districts:—With Hampshire District in Holyoke. Regular meeting in October.

Suffolk District:—Stated Meeting, October 18, 1922. Combined meeting of Boston Medical Library and Suffolk District, November 22, 1922; December 27, 1922; January 31, 1923; February 28, 1923; March 28, 1923; Annual Meeting, April 25, 1923.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Hist. The date for each speaker has not been announced.

Middlesex North District:—Meeting Wednesday, October 25, 1922; Wednesday, January 31, 1923.

The four western districts plan to hold a joint meeting early in October.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

Plans are being made for a joint meeting of the Worcester and Western North districts in October.

Massachusetts Medical-Legal Society will meet Wednesday, October 4, 1922, at 2 P. M., at the Boston Medical Library. Ernest L. Hunt, Secretary.

October, 1922. Boston Tuberculosis Association. Tuberculosis Institute for Physicians will be held on October 5 and 6 at the Massachusetts General Hospital, Bernice W. Billings, Boston, Executive Secretary.

The New England Society of Psychiatry will hold its next meeting on October 5th, at the Connecticut State Hospital, Middletown, Connecticut. Readers: Dr. Walter Timme and Frankwood E. Williams, New York City.

WASHINGTON MEETINGS:—The Convention of the American Red Cross will be held in Washington, Oct. 9, 10, and 11. The American Child Hygiene Association meets in Washington, Oct. 12, 13, 14.

New England Dermatological Society. Wednesday, October 11, 1922, at 3:30 P. M., in the Skin Out Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

The Fifty-First Annual Meeting of the American Public Health Association will be held at Cleveland, Ohio, October 16-19, 1922. Headquarters will be at Hotel Statler.

The American Association of Oral and Plastic Surgeons will hold their annual meeting at the Medical Library, Boston, on October 20th and 21st.

Clinical Congress of the American College of Surgeons will be held in Boston, Mass., on October 23-27, 1922, Franklin H. Martin, Chicago, Director-General.

Massachusetts Association of Boards of Health, October 26, 1922, Boston, Mass., W. H. Allen, Mansfield, Mass., Secretary.

New York and New England Association Railway Surgeons 32nd Annual Meeting at New York City, October 28, 1922, Donald Guthrie, Sayre, Pa., Secretary.

November, 1922. Massachusetts Society of Examining Physicians. (Date and place of meeting undecided), Hilbert F. Day, Secretary. National Cancer Week, November 12 to 18.

December, 1922. New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3:30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

January, 1923. Massachusetts Society of Examining Physicians. (Date and place undecided), Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston, W. H. Allen, Mansfield, Mass., Secretary.

February, 1923. New England Dermatological Society Meeting, February 14, 1923, at 3:30 P. M., in the Skin Out Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

March, 1923. Massachusetts Society of Examining Physicians. (Date and place undecided), Hilbert F. Day, Secretary.

April, 1923. New England Dermatological Society Meeting, April 11, 1923, at 3:30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston, W. H. Allen, Mansfield, Mass., Secretary.

May, 1923. Massachusetts Society of Examining Physicians. (Date and place undecided). American Pediatric Society Meeting, May 31, June 1, and 2, 1923, at French Lick Springs Hotel, French Lick, Ind., H. C. Carpenter, Secretary.

June, 1923. American Medical Association, San Francisco, June 25-29, 1923, Alexander R. Craig, Chicago, Ill., Secretary.

July, 1923. Massachusetts Association of Boards of Health, July 26, Nantasket, W. H. Allen, Mansfield, Mass., Secretary.

*Deceased Sept. 2, 1922.

PRESIDENTIAL ADDRESS.

SOME CHANGES IN MEDICAL TEACHING AND SURGERY.*

By C. A. PORTER, M.D., BOSTON.

THE custom of having an annual presidential address, before such societies as ours, must occasionally result in much suffering to its members. To-night, therefore, the address will be short, for I shall only give my personal experience, with a few of the surgical changes which have taken place since men of my age graduated.

I want to call your attention to certain tendencies, now showing themselves, all, of course, marking progress, though at times this may seem to be sidewise, if not backwards. It is hard, even for those of us who are in close contact with surgical teaching, to realize how much more knowledge is required of the student now than thirty years ago. We had our didactic lectures and weekly visits of thirty or forty students, following the professor through the wards. Some out-patient work was demanded, also bandaging on models, and the application of splints and apparatus. Once a week, operations were performed in the large amphitheatre, attended by

students from all the classes. As most of these operations were external, the student obtained a fair understanding of their general conduct and technique, and learned to admire the resourcefulness and brilliant operations of the master surgeons. Anatomy was considered of great importance, and was closely linked with surgery at the Harvard Medical School. A fourth-year course in anatomical landmarks and operative surgery, although an elective, was eagerly chosen. There were surgical clinics, in which the diagnosis was made by the history, symptoms, and physical examination, aided by a few simple tests. None of the more modern methods of investigation were then known. To become a successful teacher, long experience and a strong personality were necessary. There was very little surgical research, and practically no animal work. I was present when the late Professor Halsted of Baltimore came to the school and demonstrated the advantages of learning intestinal suture on dogs rather than on human beings. These were the days when surgeons came from far and near to see Dr. John Homans perform ovariectomies with a large trocar, pedicle clamp and the Staffordshire knot; and hysterectomies with Kocher's wire clamp, a turn a day, until the stump slipped back, at the end of a week.

From that time until now, certain tendencies have become more and more clear. Anatomy, exceedingly well taught, has become, with one exception, largely divorced from surgery, and the surgeons no longer work and teach in the ana-

*President's address before the New England Surgical Society meeting, Burlington, Vt., September 29, 1922.

tomical department. Operative surgery has been omitted. Work on animals for technique and research has much increased. The huge ward visits of the second and third year have been replaced by small sections, and in the fourth year, under personal supervision, the student, for two months, spends the day in the ward, laboratory and operating-room, in intimate contact with patients. The big amphitheatres have come to be less and less used, as internal operations increased, and were performed in small rooms. No longer do we see the silent group about the table, but in most clinics, the case is discussed, the steps of the operation are explained, and the surgeon must *operate and teach*, at the same time, in order to maintain attendance and attention.

With the gradual development of sub-departments of surgery, such as genito-urinary surgery and orthopedies, with the still further division into such specialties as brain and nerve surgery, etc., with the still more refined methods of diagnosis and special operative technique, it became impossible for a student to acquire the necessary knowledge in four years.

In addition, came the innumerable methods of investigation in the laboratory, and all sorts of special tests, with all of which he must have some familiarity. Instead of graduating for practice at the end of four years, not a few, but a large majority of the students now add an internship of one or two years; at the large hospitals, a paid resident surgeon's appointment is sought by an increasing number of hospital graduates. Year by year, a change has come over medical teaching. The younger man, without great experience, but with enthusiasm and knowledge of modern scientific research, is giving much of the instruction to small groups of students.

Commencing this year, the Harvard Medical School is to make a definite change in its curriculum. The Faculty has become convinced that the students' hours are too much occupied, and emphasis is to be placed on the fundamental subjects. Accordingly, the number of hours devoted to didactic lectures, and to a less extent to the clinics, has been reduced about one-third in the major subjects, and still more in the specialties. Two afternoons a week are left free for study or a choice of voluntary courses, offered by the various departments. If the making of a thoroughly competent surgeon is to require all these years of undergraduate, hospital, and post-graduate work, there must be established some standard in the future, by which such an ethical and qualified man may become known to the community; a standard, which in time, will be insisted upon by the general practitioner and other surgeons. For this reason, in spite of inevitable mistakes, I believe all of us should do our utmost to aid the work of the American College of Surgeons.

During the last ten years, in the large hospi-

tals, special assignments of a group of similar cases, where unsolved surgical problems existed, have been given to one or more individuals for a specified time. After an intensive study has been carried on, and the end-results of the treatment determined, the plan is to return these cases to the general service, or to reassign them to other individuals. At the Massachusetts General Hospital under this system, we formed the fracture service, and have assigned such rare cases as cancer of the cervix, pulmonary surgery, peripheral nerve surgery and toxic goitres, believing that more advance would thus be made, than if a member of the general staff had only an occasional case. Such specialization must, however, be limited, otherwise the general service suffers, while the individual may acquire an undeserved reputation as the only man who can do a certain kind of work. I suggest that this same system is even more valuable in hospitals of moderate size where, in addition to a few months of regular service, an individual would have a small series of cases for a year.

Throughout the country, less and less surgery is done in the private house. The day of the emergency appendix with the pocket knife, spoon retractor, candle snuffer, and a bit of twine has passed forever, unless it be in some remote farmhouse (if such exists), where the Ford car cannot penetrate, and bring the patient to the hospital. Gasoline transportation and the remarkable growth of the small hospital, both public and private, have entirely changed the aspects of modern surgery, and introduced new questions, to which the answer is very difficult. In almost every large town in New England, there is now a hospital, with a regular staff in attendance.

In our present stage of evolution, no special qualifications are necessary for the practice of surgery. At such a hospital, there is almost always a good operating-room, in charge of an excellent nurse. According to its size and endowment, there is an x-ray apparatus and a laboratory, with more or less scientific equipment. To such a hospital are now brought two types of cases,—the emergencies, to be operated upon by the local surgeon or a consultant, and many chronic cases for diagnosis, and perhaps too often for surgical treatment. These cases were previously taken by the general practitioner to a larger medical center, often to the chief cities.

There is a marked difference between a case of appendix peritonitis and one brought in with a questionable diagnosis of chronic ulcer or cancer of the stomach. In the first, the diagnosis is obvious, and immediate treatment is indicated. A reasonably qualified man should be successful. In the second case the diagnosis and treatment may be doubtful, and will often require either very special methods of examination, an unusual experience in similar cases, or a technique learned by long practice only. The question,

"Should the operation be done?" depends often for its answer on another, "Who is going to do it?" This same question arises sometimes within the walls of large hospitals. The Utopian ideal that the patient should always have the most competent surgeon will never come true, but it is to such societies as ours that the community looks for guidance. Quietly, tactfully, but firmly, we should do all in our power to influence the general practitioner, with whom the final decision rests, to send his patients only to ethical and qualified men. We should ourselves realize, furthermore, that with all the modern refinements in diagnosis and technique it is no disgrace for a general surgeon to refer a patient to another man, unusually qualified in a particular field.

I have spoken of the long course of study and hospital work, which a modern surgeon must take. To this, fortunately, there are exceptions. Such is the energy in this country of many men, that they give up practice for a time, travel, visit clinics, take post-graduate work, and owing to natural ability, make of themselves competent, practical surgeons. So long as such men recognize their limitations, the community is safe.

Far too many laparotomies are done without preliminary study: many a so-called interval appendix has been removed because the operation was easy and safe. Further study showed ureteral calculi. It is appalling how many cases of cancer of the rectum are diagnosed, and occasionally operated upon for hemorrhoids, without even a high rectal examination. Many of these errors come from improper interpretation of x-ray plates, unreliable technique in carrying out laboratory work, and in taking as a fact, the results of special investigation, in which the worker lacks both training and experience. On the other hand, we have nothing but admiration for the surgeon who, finding unexpectedly a condition beyond his ability to treat, closes the wound, and refers the patient to a more experienced consultant. It would take too long to discuss other important changes. Without further comment, I will mention the increasing activity of the State and Public Health Service, Industrial Surgery, with its rapidly increasing efficiency, the Workman's Compensation Board, Social Service, Diagnosis Clinics at the hospitals, and Group Medicine in private practice. All these and other problems must work out salvation.

Before closing, I wish to thank you for the honor you have done me, and to assure you of my continued interest in our society. May I add a thought in a lighter mood? For centuries the cause of lues was sought, and sought in vain. When found at last, it proved to be a *corbiscule*, thus justifying the time-honored association of Bacehus with Venus.

FACTORS IN DYSPEPSIA.*

BY FRANCIS W. PALFREY, M.D., BOSTON.

DYSPEPSIA is commonly understood to mean discomfort connected with gastric digestion in cases where the diagnosis of organic disease such as ulcer or cancer cannot be established. Since it occurs in different types, it is desirable to recognize these by speaking in the plural of dyspepsias. These figure prominently in general medical practice, but our knowledge of them is not yet such that we can treat them either rationally or empirically with complete success.

The subject of the dyspepsias has interested me from the fact that it has baffled us in the past, in spite of the many hints that seem as if they ought to offer solutions, if only we could read them. It is a tantalizing situation, since so much seems to lie so little beyond our grasp. But the hopeful factor to me has been the feeling that the more searchingly I have gone into individual cases, or groups of cases, the more suggestions I have obtained tending to connect clinical symptoms with deviations from the normal physiology.

My method of attacking the subject has been different from that of most recent investigators, in that they have devoted themselves more largely to objective tests, whereas I have attempted the more uncertain and less scientific method of trying to identify and analyze the patients' subjective symptoms. I must admit that I am attempting to build on insecure foundations, and that my structures are not safe against falling to the ground. Still I feel that there is a chance that by ascending these insecure structures I may get a wider view than if I were to put all my material into foundations. We must remember that dyspepsias are complexes of symptoms, rather than objective cachexias. Most patients do not complain primarily of undernutrition, but rather of discomforts connected with digestion. Many patients who complain of dyspepsia are found on objective tests to have no deficiency of nutrition. Also in routine tests individuals are found whose digestive processes deviate markedly from the normal, both in the directions of deficiency and of excess, but who, in spite of these deviations, have no symptoms of dyspepsia. It seems to me, therefore, that, both in investigation and in clinical dealing with the individual case, we should deal primarily with symptoms, and with other abnormalities only as they may contribute to symptoms. The patients come to us for relief of certain discomforts, and it is only by learning to identify symptoms from the patients' descriptions, or from other evidence, and by

*Read before the Fall River (Mass.) Medical Society, March 22, 1922.

learning ways by which these symptoms may be remedied, that we can furnish such relief.

Gastric digestion is a complicated and delicate process. I remember vividly a demonstration early in my medical school course, in which the stomach of a dog killed immediately after a full meal, was laid open to view, showing a large, moist mass composed of lumps of meat, bread and potato. A dog's dejections are the familiar small masses and coils of homogeneous fecal material; and even of their small bulk only a part is formed of material ingested, the chief bulk being composed of bacteria which have grown in the intestine. Most of the bulky meal, therefore, is digested and absorbed. Of course the absorption and part of the digestion occurs in the intestine, but the stomach begins and makes important progress in the process.

The chief functions of the stomach are two. First, it receives each meal for temporary storage, and passes it along little by little through the pylorus into the intestine, as the small intestine is able to receive it and attend to it. Second, it has the function of digesting or reducing to a fluid state all protein substances,—meat, fish, cooked egg, milk curd and vegetable proteins. In addition to this, some conversion of starches and sugars under the influence of the saliva may go on in the fundus, and the peristalsis in the pyloric portion may have some mechanical effect in dividing soft solid particles, but these actions are probably of little importance.

Viewing thus the digestion in the dog,—and human digestion is undoubtedly closely similar,—the course of gastric digestion, wonderful as it is, seems at first sight fairly simple and trouble-proof. We have all seen the disappearance of a slice of coagulated egg albumin incubated in a test-tube of pepsin-hydrochloric acid solution. We have all been taught that the mucous membrane has a natural immunity to this pepsin-hydrochloric acid. We can watch the peristaltic waves of the stomach under the fluoroscope until the stomach is empty. It is hard so far to see why anything should ever go wrong.

But let us transfer our attention from the dog, who cannot complain of dyspepsia, to the human being. All the facts that I have mentioned above apply also to human digestion. Yet certain human patients, in whose gastric contents according to our ordinary tests no notable abnormality is found, and in whom the radiologist recognizes no departure from what he considers normal in the position, outline, or movements of the stomach, still complain of discomfort which, they are convinced, is connected with their digestion. This leads us to suspect that we have been too hasty in regarding the stomach as a chemical and mechanical automatic machine which should not get out of order, and that disturbances may occur in it

which our present methods of objective examination are not sufficiently delicate to detect.

The truth seems to be that although a normal stomach under normal conditions is practically sensationless and automatic, the stomach is an organ which is far more sensitive than I have suggested hitherto to influences which may cause it to produce ~~abnormal sensations and~~ to depart from its normal function. In this way it is to be contrasted with the heart. If the stomach were as incapable of originating sensations as the heart ordinarily is, if gastric peristalsis were as free from factors which disturb its action as the myocardium, and if the pylorus were as uniform in its action as the heart valves, I suspect that dyspepsia would be less frequent. But the stomach is a more temperamental organ, and is also called upon to adjust itself to more variable conditions. It is lined with a mucous membrane which, we know, under excessive stimulation becomes hyperemic. Although it seems to be less endowed with a function of sensation than is the skin, still it is hard to admit that it is not capable of sensations of discomfort or pain when it is subjected to unfavorable influences, as, for instance, after the ingestion of corrosive poisons. And it is constantly exposed to varying influences, not only to the wide variety of food and drink ingested, but also to changes that may occur in these while they are in the stomach, and also to its own powerful chemical secretion. The motor function of its musculature and the secretory function of the mucous membrane are peculiarly subject to influence by circumstances of environment, emotions, and sensations not primarily involving the stomach, such as those of taste and smell. Also the stomach for normal functioning requires normal functioning of its two orifices; and both of these, according to my conception, are liable to misbehave without reference to hitherto recognized organic disease.

First, as to the pylorus. I have already mentioned that the stomach receives food for storage and peptic digestion, and discharges it little by little to the small intestine. The pylorus has absolute control over the rate of discharge. If the pylorus is closed nothing passes. If the pylorus is open it requires little force of gastric peristalsis to cause any fluid contents to pass. Now clinical investigators in the past, in their enthusiasm for chemical gastric analysis, have described conditions in which they found highly acid liquid contents in the stomach. They jumped at once to the conclusion that this was necessarily due to an excessive rate of secretion of hydrochloric acid, overlooking the alternative possibility that retarded discharge of the normal amount of secretion could cause the same findings, and that also, granted the existence of an excess of gastric secretion, a sufficiently permeable pylorus would rapidly drain the excess away. There is reason to suspect, therefore, that the pylorus, from its command over

the outflow from the stomach, may by improper functioning cause or contribute to abnormal conditions within the stomach; especially by retaining in the stomach food and secretion that so far as the stomach is concerned are ready to pass on to the intestines.

This leads us to consider what is known of the pylorus and its action. The pylorus is the narrow outlet of the stomach, with its surrounding sphincter of smooth muscle, which, when in contraction, closes the outlet, and, when relaxed, leaves the outlet patent. It is occasionally capable of tight spasmodic contractions, which have been described by surgeons as seen by them at operation. But such pylorospasms are unusual and abnormal. On the normal behavior and control of the pylorus our best evidence is from the extremely important observations of Cannon.¹ Cannon reports that in normal digestion the pylorus is closed, but that it relaxes and allows the passage of a jet of gastric contents at more or less periodic intervals under the following conditions: The first signal for opening of the pylorus is the appearance of free hydrochloric acid on its gastric side. Then a jet passes into the duodenum and the pylorus closes, apparently from the effect of the presence of acidity within the duodenum. The pylorus then remains closed until the acidity of the contents of the duodenum is neutralized, by the pancreatic juice, the bile and the duodenal secretion. Then, if there is still free acid on the gastric side, the pylorus again relaxes and another jet passes. And so the process goes on, the pylorus acting as a flood-gate to admit acid gastric contents to the duodenum only in such amounts as can be neutralized promptly in preparation for pancreatic digestion. It is true that there is reason to suspect that this action of the pylorus is sometimes in abeyance. Water seems to pass through the stomach more rapidly than is consistent with its subjection to this process. In some cases of achylia gastrica the stomach seems to empty even more rapidly than normally in spite of absence of the acid signal for opening of the pylorus. Also McClure, Reynolds, and Schwartz,² in certain experiments on human cases, have failed to obtain evidence that these cases under the conditions of their experiments behaved in accordance with Cannon's theory. But these observations do not seem to me sufficiently representative of all conditions of normal digestion to warrant our discarding the whole theory. They rather seem to me to point to exceptions. Also Alvarez,³ from his work on the muscular action of the digestive tract, throws doubt upon the chemical control of the pylorus, and in his concentration upon peristalsis seems to discount or even at times to disregard the action of the pylorus. But Cannon's findings are too exact, and his theory is too consistent with what the pylorus should do for the protection of the duodenum and jejunum, to be seriously doubted.

I have already expressed the opinion that when acid fluid contents are retained in the stomach,—and this includes many cases of ulcer as well as many that are still considered functional dyspepsias,—the fault must be laid to the pylorus. Considering this in the light of Cannon's teachings, it has long been my belief, since in these sufficient acid is clearly present to furnish the first signal for opening, that the difficulty may lie in the neutralization of acid in the duodenum, by the pancreatic secretion, the bile and the intestinal secretion.

The suspicion therefore arises that in dealing with dyspepsia of the so-called hyperacidity type, with or without ulcer, we may be dealing with stomachs which are not themselves primarily at fault, but which are forced to complain because the organs whose secretions enter the duodenum are not keeping pace, and consequently the stomach's finished work is accumulating on its hands.

This leads us to consider what is known of the factors which control the flow into the duodenum of these neutralizing secretions. The pancreatic juice is probably the most important of these since it is the most strongly alkaline in reaction. Unfortunately, in man there are few observations as to its flow; these show merely that the flow takes place during the period of digestion. In animals it is shown that the flow varies in amount and in duration according to the type of food given, and that it is stimulated by the presence of acid in the duodenum. This stimulation by acid in the duodenum seems to be not a nervous but a chemical one, since by treating duodenal mucous membrane with weak hydrochloric acid a product is obtained which on intravenous injection into animals will cause an increase in the flow of pancreatic juice. We have, however, no proved clinical means of increasing the pancreatic juice in man. Of the duodenal secretion still less is known. The bile is probably of less importance than the pancreatic juice as a neutralizer of acid, since it is less strongly alkaline and is normally no greater in daily amount. It seems to be secreted continuously, but discharged into the duodenum intermittently, chiefly as chyme enters the duodenum. But over the flow of bile we have more control. As Pfaff and Balch⁴ have shown, its amount can be increased greatly by the giving of ox-bile by mouth. Clinically, as I have reported before⁵, the administration of bile or bile salts so as to increase the amount of bile is of service in improving the so-called hyperacidity symptoms. If any theoretical suspicions are correct a method of stimulating the flow of pancreatic juice, if we had one, might be of still greater advantage; but even if my theory is wrong, I can still vouch for the fact that bile preparations give symptomatic improvement.

The cardiac orifice of the stomach has received surprisingly little attention in medical investigations except as an opening through which the stomach is entered. It is to be inferred from

such current teachings as bear upon the subject at all that the cardiac orifice should normally resist all passage in the upward direction, whether belching, regurgitation or vomiting. It is my observation, however, that few persons are free from a little, effortless, half unconscious belching after meals, and that such effortless belching, where noticed at all, is an act commonly attended with some slight satisfaction, and seems to indicate a wholesome rather than a disordered gastric function. On the other hand, as I think you will agree, a desire to belch but an inability to do so without marked effort or at all,—“gas on the stomach” or “gastric trouble” as patients are fond of calling it,—occurs with conditions of digestion not satisfactory to the patient. Regurgitation and, still more, vomiting are always abnormal. But in these acts, too, especially in vomiting, it is a matter of common observation that the act may be easy or difficult, and that where it is difficult it involves a more serious disturbance. The cardiac orifice itself is surrounded only by a weak sphincter of smooth muscle, capable of resisting only little pressure. But the oesophagus in man approaches the stomach somewhat obliquely, entering internal to and behind rather than above the fundus. It is strongly suggested to my mind that, in patients who have difficulty in belching or vomiting, the difficulty may be the result of lateral pressure or kinking of the cardiac orifice or lower part of the oesophagus. While I have no proof of this I offer it as a possibility which seems to me to deserve consideration and further investigation.

The stomach as seen at autopsy or by fluoroscope always has contents of two kinds in varying proportions, the fluid or semifluid, and the gaseous. Our attention in the past has been so largely focused upon the behavior and disposition of food, drink and secretions that we have been prone to forget the gaseous contents. Still it seems to be a provision of nature that the stomach should be in part filled with gaseous contents, and provisions of nature are, as a rule, not without some useful purpose. The gaseous contents of the stomach have been sufficiently studied to show that, unlike the gases of the intestines, they are not products of fermentation and putrefaction, but almost entirely air. Moritz⁶ has shown that the pressure is normally about 8 cm. of water, and that pressures of 20 cm. or over cause discomfort. Now it is commonly taught that the stomach is normally protected against increases in internal pressure by a mechanism through which each swallow ingested, results in a corresponding relaxation of the gastric musculature. But I have already alluded to the sensitiveness of the gastric musculature to various influences. It seems too much to expect of an organ with such an erratic musculature to maintain always normal internal pressures without a safety valve. It is strongly suggested to me that such a safety valve is to

be recognized in the normal cardiac orifice in communication with the normal gas-bubble.

If this is true, such abnormal difficulties of upward passage through the cardiac orifice as I have suggested above may well explain uncomfortable feelings of pressure within the stomach.

Now, looking back over what I have said so far, let me enumerate the abnormal conditions that I have mentioned which seem to me to warrant suspicions that they may be the bases of symptoms. First, hyperemia of the mucous membrane. Second, abnormalities of secretion, either in the direction of excess or toward diminution or absence. Third, abnormal motor action, increased, diminished or disturbed. Fourth, retention by the pylorus of gastric contents ready to pass into the duodenum. Fifth and last, valve-like resistance of the cardiac orifice.

Hyperemia of the gastric mucous membrane was seen by Beaumont⁷, nearly a hundred years ago, when through the gastric fistula of his patient, St. Martin, he viewed the interior of the stomach under a variety of conditions of stimulation. The mucous membrane had markedly this appearance of hyperemia following St. Martin's over-indulgence in alcohol. For symptoms that may be connected with such hyperemia, therefore, we may get suggestions from those which occur after the ingestion of overstimulating substances or after overuse of alcohol. In such conditions the most constant symptom is a burning sensation or “raw feeling” in the epigastrium commonly known as heartburn or pyrosis. There is also a tendency to vomit, more or less promptly, after the ingestion of food. These two symptoms seem to me strongly suggested as subjective manifestations of this hyperemia. These same symptoms, it is true, do not occur only after the ingestion of irritants. They occur also in the so-called “acute catarrhal gastritis” and in connection with acute infectious diseases. But reasoning backward, it does not seem to me improbable that here too we have a hyperemia of the gastric mucosa, perhaps from catarrhal inflammation. So I have come to the tentative conclusion that heartburn with a tendency to vomit is evidence of hyperemia of the general gastric mucosa.

But heartburn in these cases which I suspect of representing general hyperemia of the gastric mucosa is rarely intense, except in corrosive poisonings with probable erosions or ulcerations, and in pronounced cases is less prominent than the tendency to vomit. Severe heartburn, on the other hand, is more common in connection with accumulations of acid contents due, according to my conception, to delayed discharge through the pylorus. In these there is less tendency to vomiting. It is suggested to me that these cases of heartburn with acid contents and less tendency to vomit represent irritation chiefly of

the pyloric portion of the stomach, whether hyperemia, erosion or ulcer.

Abnormalities of secretion and of muscular function often seem to bear some relation to each other and are therefore best considered together. Both are found to vary from the normal either in the direction of deficiency or toward excess, and often apparently in sympathy with each other.

First, there are cases in which there seems to be a general inhibition of normal functions of the stomach. An instance of this which I met some years ago is as follows. A physician, 60 years of age, who had previously had a normal digestion, had his first attack of angina pectoris (of which he died suddenly less than a year later) within half an hour after a heavy noon meal containing steak and potatoes. The attack of angina was severe and typical, and he knew what it meant. Through the afternoon and night he was excited and apprehensive but not notably uncomfortable. At eleven o'clock the following forenoon, twenty-three hours after the meal had been eaten, he was nauseated and vomited a large amount of the meat and potato eaten the previous noon, and these articles in the vomitus showed no evidence of digestion during their twenty-three hours in his stomach. He had no further digestive trouble. He had had amyl nitrite but no morphia.

This case has always seemed to me an unusually good example of complete inhibition of gastric digestion, due either to the severity of the angina pain or to the psychic disturbance resulting. But similar instances of vomiting of little digested material after shorter intervals are not rare. They occur especially when the food has been eaten during excitement, distress or illness, or when the same influences have become active shortly after a meal. The chief symptoms that we can associate with such occurrences are disinclination to take the food, and, after it is taken, a sense of constant weight in the epigastrium and gradually increasing nausea until the vomiting occurs. Such vomiting may be an isolated event in the life of the patient. But there are also cases which may be considered to form one class of chronic dyspeptics whose condition consists of such symptoms recurring frequently or constantly. These patients complain of poor appetite and say that what they do eat "lies like lead" in their stomachs; they frequently have nausea and this sometimes leads to vomiting; they are apt to be persons of poor muscular development and posture, and to have headaches and nervous exhaustion. Analyses of gastric contents are apt to show subnormal acidities, and the fluoroscope often shows atonic and not seldom pro-lapsed stomachs. An occasional variation upon the usual symptoms in some of these is the appearance at irregular times of a strong craving for food, which may or may not be well tolerated. It is reasonable to consider such symptoms as manifestations in gastric function

of states of nervous exhaustion and instability.

Achylia gastrica, or the condition of continuous absence of gastric secretion, is of disputed nature. It may belong in the above group, but the gastric and general symptoms are often less marked, and the motility may be normal or increased with rapid emptying of the stomach. It is worth noting in connection with what I have said as to the function of the pylorus that achylia cases are apt to have intestinal symptoms.

Conditions of increased secretion are a little difficult to distinguish from those which, according to my conception, are not conditions of increased secretion but rather conditions of accumulation of normal secretion by delay of its discharge through the pylorus. It is my belief that many cases that have hitherto been considered as due to increased secretion in reality are due only to abnormal accumulation. Still there can be no doubt that in cases called hypersecretion or gastroenterorrhoea, in which the stomach, even in the absence of food, fills with large amounts of acid gastric juice which has to be vomited or washed out, there must be an excess of secretion, and a disturbance of the normal timing of secretion in response to food. We must recognize therefore that hypersecretion exists, and although the extreme cases are rare, less marked cases are undoubtedly more common. At the same time, it seems to me necessary to assume that when these accumulations of acid secretion in the stomach develop, their accumulation must mean that the pylorus has not risen to the occasion to supply an outlet for it. The chief symptoms are a feeling of fullness increasing to a pain of a quality which suggests either pressure or muscular contraction, and then vomiting of large amounts of acid fluid. The possibility of pylorospasm, in addition to increased secretion, is strongly suggested.

The activity of muscular contractions of the stomach as seen by the fluoroscope, in cases with normal or highly acid contents, may be deficient, normal or increased. It has been my impression that, provided the mucosa, the secretions and the behavior of the orifices are normal, the variations in muscular action are of no great importance in the production of symptoms. Atony or deficient peristalsis in connection with deficient or inhibited secretion has been mentioned already. There is reason to suspect that increased peristalsis or increased tonicity may contribute to the symptoms in the hyperacidity syndrome, or in the cases that I attribute to valve-like resistance of the cardiac orifice, producing the sense of epigastric pressure. But in these I take the motor disturbance to be a contributing and not a prime cause of the trouble. Still, it may be that if Alvarez's theories of the interrelation of the peristaltic activities of the digestive tract as a whole are developed, we may receive new illumination.

My belief that the type of dyspepsia hitherto known as hyperacidity has its basis, at least in part, in a not sufficiently rapid discharge of acid contents through the pylorus, gains support from an examination of the associated symptoms. The intelligent patient commonly gives the following story. At meal times he is hungry but he fears to eat much because he has found that a full meal will cause him to suffer later. After eating he soon begins to feel a burning discomfort in the epigastrium, gradually increasing. He feels that this discomfort comes from the place where the meal has gone to, as if the meal were burning or irritating whatever is surrounding it. He may belch wind but that gives little or no relief. He is apt to regurgitate, and the fluid which rises to his throat is sour and irritating, convincing him that the distress down below, where this sample came from, is due to the irritant quality of this fluid. If the trouble gets bad enough he vomits, and then feels better. From that time on, he knows that emptying the stomach will give relief. During his symptoms his constant wish is that the contents of his stomach would pass through more quickly in the normal manner, but he often becomes discouraged in waiting for them to do so, and induces vomiting. He usually learns that sodium bicarbonate will give temporary relief and uses it frequently, but recognizes that it is only an aid in tiding over the single period of discomfort in which it is taken. Let us attempt a translation of this account into medical terms. Heartburn, or burning sensation where the meal lies in contact with its container, may be translated as an irritated state, probably a hyperemia, of the mucosa of pyloric portion of the stomach; belching and regurgitation, as increased tonicity or motor activity of the stomach in response to irritation; acidity and irritating quality of regurgitated fluid, as pepsin-hydrochloric acid; relief by vomiting or by taking soda, as evacuation or neutralization of pepsin-hydrochloric acid; sense that the discomfort would be relieved if the meal would pass out of the stomach more quickly, as retention by the pylorus. From this translation we may construct the theory that in these patients the symptoms are caused, or at least contributed to, by irritation of the stomach from the accumulation of pepsin-hydrochloric acid, continuing until this pepsin-hydrochloric acid is removed. The patient who has studied physiology says that this is entirely in accord with his sensations. But here we meet with objections: that free hydrochloric acid and pepsin are in contact with the pyloric mucosa in all normal digestion but produce no discomfort; it is a time-honored teaching of physiology, and obviously true in all normal men and animals, that the gastric mucosa is immune against the action of pepsin-hydrochloric acid; also, it is currently taught that the stomach itself is incapable of sensation, and that the burning sensation which seems to come from the stomach

is really due to acid regurgitation into the oesophagus. These teachings have been accepted by physicians, adding to the mystery of the situation. But they do not satisfy the patient. He insists that his stomach at least is not immune or sensationless. He can feel the burning and knows that it comes from where the food lies that he can still feel in his stomach. Nor is he better pleased with the suggestion that his trouble is "gastric hyperaesthesia" and a neurosis.

Let us consider these subjects of sensation and of the immunity further. First, as to the supposed lack of sensation of the stomach. This has been inferred from experiments in which hydrochloric acid solutions introduced by tube into the stomach resulted in no sensation. But to my mind this is not conclusive since the experiments do not seem to have duplicated the condition of long contact which we assume to occur in our patients. And as to the immunity, is it reasonable to suppose that this immunity is absolute, as if the stomach were lined with platinum? Is it not more consistent with most facts of physiology that it should be only a relative immunity, ordinarily sufficient but liable to break down when too strenuously attacked? We know that it breaks down in gastric ulcer which is only a step beyond the condition which we are considering. May not the truth be that pepsin-hydrochloric acid, when it is not passed on through the pylorus in proportion to the rate of its formation, can, by accumulation and long contact, repeated after every meal, break down this immunity, so that in the end the gastric juice does attack the mucosa, causing irritation, hyperemia, erosion or even ulcer? And if this occurs, is it not more the fault of the pylorus in not passing on the eroding fluid, even if this is formed in excess, than the fault of any increase in secretion; and might not an abnormally sluggish pylorus produce the situation with no increase of gastric secretion at all? I believe all this to be probable although it is at present incapable of proof.

The symptoms of a resisting cardiac orifice seem to me obvious when once our attention is directed to them, and surprising only from the lack of attention that they have received in the past. Their neglect in the past I can explain only on the ground that discomforts due to resistance to belching are seldom severe enough in themselves to be disabling, and reach their severest grades in connection with other disorders which have distracted attention from them. In the minds of patients, and also of some physicians, there is a misconception of what belching means. Many patients conceive of the "gas" which they raise in large volumes as a product of fermentation, whereas the truth is that gas-producing fermentation in the stomach of any importance is seldom if ever met except in the cases of marked organic stenosis of the pylorus. Except in these cases with a rare organic disease the "gas" raised is

simply a specimen of the air that is normally in the stomach, or air that has been swallowed in "cribbing," expelled on account of increased tonicity of the stomach. I have already expressed the opinion that easy, quiet belching is to be regarded as a normal process intended to insure the intragastric pressure against undue elevation. But certain patients have more or less habitually a sense of pressure in the epigastrium which they feel should be relieved by belching, but they are able to belch only with difficulty and unsatisfactorily. With the feeling of unrelieved pressure in the stomach are often associated jerky spasmodic contractions of the epigastric muscles (perhaps also of the diaphragm), which are more or less uncomfortable. Patients with these symptoms often resort to the various dyspepsia tablets containing sodium bicarbonate with an irritant aromatic. These, while they usually give temporary relief, tend, when taken habitually, to set up further irritation. Many patients also learn the trick of cribbing, which also seems to aggravate the disorder. Sometimes, too, the symptoms of inability to regulate intragastric pressure are associated with, and increase, the discomfort of other disorders, such as the hyperacidity complex.

From these considerations the following classification of common types of dyspepsia seems to me suggested:

First. Irritable, irritated, very likely hyperemic, states of the mucosa, from improper diet, drugs, alcohol and perhaps catarrhal inflammations, with as presenting symptoms mild pyrosis or "raw feeling" and, in severer instances, a tendency to vomit promptly on the ingestion of food.

Second. Depressed or inhibited states of secretory and motor function, due largely to reflex and psychic influences, with the presenting symptoms of anorexia, sense of weight in the epigastrium, nausea, and vomiting of food not digested in proportion to the duration of its retention in the stomach.

Third. Hypersecretion or gastrosuccorhoea with probable pylorospasm, with as symptoms an increasing sense of fullness, pain, and vomiting of acid fluid in which undigested food is less in evidence.

Fourth. Those cases to which the term hyperacidity is so generally applied that it is not likely to be given up readily, but which, according to my belief, are fundamentally due to a rate of pyloric discharge which is not keeping pace with the acid secretion in the stomach, whether the latter is increased or only normal. This insufficient rate of discharge through the pylorus may be due to deficiency in the neutralizing fluids of the duodenum. The symptoms I believe to be due to irritation, hyperemia, erosion or, in extreme cases, ulceration of the mucosa of the pyloric portion of the stomach, and are: heartburn, acid regurgitation, sense of unduly prolonged retention, and vomit-

ing; often voluntary, for relief. This group differs from the preceding one in that there is not necessarily an excess of acid secretion, and in that pyloric discharge is not abolished; it is going on, but not rapidly enough to keep pace with the secretion.

Fifth. Valvular cardia, with the principal symptom of a sense of epigastric pressure not readily relieved by belching, which may become exaggerated into habitual noisy belching and cribbing.

Combinations of more than one of the above may occur, and some may be aggravated by the coexistence of motor disturbances not yet identified.

Now, how are these five types of disorder to be treated? Here, for lack of time, I must confine myself to general principles. Besides, the details must vary somewhat in each individual case.

First, as to the group which I have attributed to irritability, perhaps hyperemia, of the lining of the stomach, due to irritants ingested or perhaps sometimes to catarrhal inflammation. Here the keynote is to put a stop to the irritation. In severer cases where some of the irritant may be still in the stomach, vomiting should be encouraged by giving warm water, or the stomach may be washed out; then the stomach should be rested by a fast of from twelve to twenty-four hours or more, in which nothing but sips of water or cracked ice are taken. If vomiting is violent after the stomach is empty a small hypodermic of morphine or atropine may be given. But the requests and suggestions of friends that various things be given by mouth "to stop the vomiting" are best rejected. I suspect that there is a stage, if we could recognize it, in the subsidence of these irritations, in which mild stimulation as by certain foods, by capsicum, nux vomica, ginger or champagne may do good. But I am convinced that in practice these more often do harm by increasing and prolonging an irritation that would have subsided sooner under simple rest and starvation. Returning appetite is commonly an indication that feeding may be resumed with milk and lime water in small amounts, then gruels, milk-toast, etc., up to a normal child's diet, and then on to a simple adult diet, with cautions against return to the indiscretions which caused the original disorder. In mild or chronic cases restriction to a simple diet of limited amount, without fried foods, pastry or strong flavorings, and enforcement of mastication, may be sufficient.

Second, as to the group of depressed gastric functions. One of the strongest hints as to the line of attack in these is the very striking improvement that often occurs in these patients if they can be given a complete change of scene or vacation in congenial surroundings. Most cases when they apply for treatment are in a state of discouragement and maladjustment to

their environment from which they see no way out. Many difficult situations are presented, but it is generally true that more can be accomplished by encouragement, and improvement of the general circumstances of daily life, both mental and physical, than by diet and drugs. In diet the most important point is to be sure that the patient has his meals at regular hours at a good home- or boarding-house table and eats moderately of what is provided, resisting the opposing temptations either to omit meals or to eat irregularly between meals. Of drugs, *nux vomica*, with a little dilute hydrochloric acid before meals, sometimes works well as a temporary expedient.

Hypersecretion with pylorospasm, failing more exact knowledge, we have to set down as a neurosis of secretion and contraction, or a reflex of unknown source. On this basis and on empirical grounds treatment should attempt to provide for a calm state of mind during meals and during their digestion; slow, moderate eating, with thorough mastication, and avoidance of articles which are believed to stimulate acid secretion, notably spices, meat flavorings and products of frying. Sometimes the attack seems to be directly precipitated by strongly acid drinks, so these should be particularly warned against. *Belladonna* and *atropine* seem to be of value. In attacks, milk of magnesia or sodium bicarbonate should be given freely, and if the spontaneous relief from vomiting is delayed, the stomach may have to be washed out.

Fourth, the group called hyperacidity, with heartburn and desire for more rapid emptying. Cases of this group are to be suspected of ulcer, according to their duration, severity and obstinacy, and if their symptoms are sufficiently severe, should be put to bed and given one of the accepted gastric ulcer diets even though the special tests of the laboratory and x-ray fail to give a positive diagnosis. Milder cases may be given merely a small bland diet at meal times with crackers and milk at 11, 5, and 10. In all cases, whenever symptoms are present they should be controlled as promptly as possible by magnesium oxide, milk of magnesia or sodium bicarbonate. Where magnesium oxide preparations have the necessary effect they are preferable for frequent use to sodium bicarbonate. But in most cases which obtain temporary relief from these agents which neutralize acid (even including some cases of ulcer), I have found that much can be done to prevent the recurrence of symptoms by giving preparations of ox-bile in enteric coated tablets with the object of increasing the flow of bile. Perhaps the most important practical point that I have to offer is that you can make many patients with sour stomach and heartburn grateful by giving them this bile treatment. Satisfactory preparations are Glycotauro tablets of Hynson Westcott and Dunning, and Ox-bile Tablets of Burroughs, Wellcome & Co. Three tablets should be given three times a day before meals,

or nine a day, for a week, then reducing. At the same time it is well to urge thorough mastication and a moderately conservative diet without alcohol, but closer restrictions in mild or early cases are unnecessary. In patients who obtain temporary relief from milk of magnesia you can be fairly confident that this treatment will give more permanent relief.

Fifth, in cases of valvular cardiac orifice or difficult belching. Not knowing the exact mechanism, we have no direct method of treating the orifice. Our object therefore should be to diminish the need of belching by reducing, so far as possible, the variations of intragastric pressure. This is best done by providing a diet supplying the necessary food value in small bulk, and the day's total should be divided between six meals instead of three at appropriate intervals. All should be eaten slowly and masticated thoroughly. Excitement, which some patients find to increase their sense of epigastric pressure, should be avoided. Patients should be persuaded to restrain all voluntary attempts to belch, and to break the habit of cribbing, which some have without being conscious of it. Irritant dyspepsia medicines should be stopped, but milk of magnesia and enteric coated bile tablets may be used if there are associated hyperacidity symptoms.

Combinations of the above-mentioned sources of symptoms should be treated by appropriate combinations of treatment.

Finally, there are certain general facts that seem to me worth mentioning for their bearing upon the management of cases of dyspepsia of various types. Most chronically disordered stomachs can still receive without symptoms most of the articles of a normal diet if only these are taken with thorough mastication in sufficiently small amounts. Patients in managing their own diets commonly have their attention too much fixed upon *what* they can eat, and pay too little attention to the amounts. Most dyspeptic patients are impatient and meddlesome with their stomachs, rather than gentle and systematic, and so become confused and discouraged. Osler mentions $3\frac{1}{4}$ ounces of meat, two medium slices of stale bread and 1 ounce of butter three times a day as a useful diet in hyperacidity. Smaller amounts of the same foods can be taken by most dyspeptic patients, and it often serves as an encouraging introduction to treatment to show the patient that he can take even small amounts of those substantial foods which he may formerly have feared, giving him reason to hope that he may gradually resume a normal diet.

SOME ASPECTS OF THE PROBLEM OF STERILITY.*

By SAMUEL R. MEAKER, M.D., M.R.C.S., BOSTON.

STERILITY is an important subject for several reasons. In the first place, it is a common condition. One marriage in every ten is childless; hence there are in this country today nearly two million sterile couples who are still at the age of potential child-bearing. Again, sterility is usually a matter of vital concern to the persons involved—in many cases the outstanding sorrow of a lifetime. In the third place, the fact that our native population is less by some millions than it might be is of national economic importance, especially in these post-war days.

The fact of sterility can be diagnosed by any layman. The cause of this condition presents a diagnostic problem of the most complex sort. Let the cause be determined in a given case, and the therapeutic question will be answered. The real problem is aetiology.

From the earliest times the reproach of barrenness has been visited upon the woman. Even in these days the wife is often the subject of unnecessary and harmful treatment when in fact the husband is the one at fault. In forty per cent. of my cases the responsibility has rested with the male. This agrees fairly well with the average of the figures for male responsibility given by other observers.

We may lay down as a cardinal principle, then, that every case of sterility is, in the beginning at least, a two-patient problem. It should be our business to rule out the possible responsibility of the male before coming to any conclusions about the female or subjecting her to treatment, even though she may present some definitely abnormal condition.

The male has a double duty to perform. First, he must produce normal spermatozoa. Second, he must deposit those spermatozoa in his wife's cervix. The older books describe in detail how the uterus dips down into the receptaculum seminis and sucks up semen into the cervical canal by rhythmic muscular contraction. There is no real evidence to support this idea. Sperm which is not ejaculated directly into the cervical canal, or at least onto the os externum, is almost certainly wasted, for its life in the vagina is very brief. In forty-three postcoital examinations made between one and two hours after intercourse I have found living spermatozoa in the vagina only four times. In most of these

cases living spermatozoa were recovered from the cervix. All this is in accord with the more extensive observations of Hühner, and supports his conclusion that spermatozoa deposited in the vagina are usually killed within an hour by the acid vaginal secretions. The occasional ease where pregnancy has resulted from semen deposited at the introitus or in the vestibule is of medico-legal interest, but must be taken as a rare exception to the general rule.

Thus the postcoital examination gives us important data about the relative responsibility of husband and wife. If normal living spermatozoa are recovered from the cervix, the male is at once exonerated; more could not be expected of any man. It is not necessary always to see the husband in such cases—an advantage sometimes, when both parties do not share equally the desire for children. It is a curious psychologic fact that a woman often resents the suggestion of possible defect in her husband, while she faces with equanimity the demonstration of faults in herself. Also, we often find that among the uneducated sexual vigor in the male is taken to be proof conclusive of his fertilizing power, and so investigation is deemed superfluous.

If dead or feeble spermatozoa are found in the cervix, and the condom-specimen is normal, we may again conclude that the male is not at fault. The trouble here lies in the hostile action of the endocervix toward normal spermatozoa.

If no spermatozoa are recovered from the cervix, and the condom-specimen is normal, then the difficulty must be of a mechanical nature, and may be due to conditions in either the husband or the wife. In the male one should consider premature ejaculation, stricture, and hypospadias. More commonly, however, the trouble in such cases is with the female. A uterus in moderate descensus allows the penis to pass up behind the cervix, and thus ejaculation into the os externum becomes impossible. If there is any foundation for the popular idea that tall women become pregnant more easily than short ones, it is to be found in the fact that in relatively longer vaginæ there is less chance of thus over-shooting the mark. Another condition familiar to all of us is the long conical cervix, often so anteflexed as to bring the external os up against the anterior vaginal wall. Operations such as that of Dudley, designed to correct this abnormality, often fail to cure sterility, because the condition just described is only one manifestation of a general pelvic infantilism. Retroversion of the whole uterus without flexion may likewise bring the cervix up against the anterior vaginal wall. This is a common cause of so-called secondary sterility. The prognosis in such cases is good if the displacement is corrected.

When normal sperm cannot be recovered from the cervix, a condom-specimen should be studied. The more obvious abnormalities of the semen—azoospermia, necrospermia, and marked oligo-

*Read before the Massachusetts Surgical and Gynaecological Society, May 17, 1922.

spermia—are easily recognized. While these are by no means rare, much commoner is another condition which often escapes recognition. I refer to relatively slight diminution in the number and motility of the spermatozoa. This represents the state called by Reynolds "lowered fertility." If such a man is mated with a wife whose fertility also is of low grade, the union is likely to be childless, even though neither person is absolutely sterile. Such a condition of lowered fertility is encountered particularly in those leading a sedentary life and taking an ill-balanced diet. It sometimes responds promptly to the simple correction of hygienic errors. Last November I was consulted by a couple who had one child nine years old; seven years ago there had been a miscarriage, and since then no pregnancy had occurred, though both parties were anxious for children. Every examination of the wife was negative. The husband considered himself to be in perfect health. As a matter of fact, he was about twenty pounds overweight. His diet was faulty, and his occupation, chemistry, was sedentary and confining. His semen showed about half the usual number of spermatozoa; of those present, perhaps twenty-five per cent. exhibited normal motility, while the remainder were feeble or dead. A diet of 2000 calories rich in vitamins was ordered, small doses of calcium lactate and thyroid extract were prescribed, and he was advised to do daily work in a gymnasium. Two months later another specimen of semen was examined, and proved to be normal in every respect. The wife missed her next period, and is now three months pregnant. We should examine semen with a critical eye. Unless the spermatozoa are entirely satisfactory in all of three respects,—number, motility, and morphology,—there is room for suspicion about the fertilizing power of the male.

The grosser seminal defects, many of which are sequelae of gonorrhea, come within the province of the genito-urinary surgeon. The hopeless cases are those where azoospermia is due to atrophy of the seminiferous tubules. Two years ago Frank Lydston proposed that in such cases, when the desire for children was strong, the following procedure might be carried out, with the full knowledge and consent of the persons involved. Sperm from a healthy donor was to be injected, via the vas deferens, into the vesicles of the husband, who would then deposit that sperm in the natural way in his wife's cervix. In one of my cases this was carried out, but without result.

The possible causes of sterility definitely chargeable to the female are systematically listed in the text-books of gynaecology, including everything from imperforate hymen up to absence of the ovaries. Such an impartial anatomical classification is unfortunate, in that the attention is likely to be focussed on some one anatomical condition which may be related only indirectly, or not at all, to the sterility. For many years much importance was attached to

anteflexion of the corpus uteri, coupled with a small cervical canal and so-called pin-hole os. It was believed that in such a uterus the point of flexion at the os internum presented a mechanical barrier to the ascent of spermatozoa, and so acted as a cause of sterility. As a matter of fact, the condition just described is seen in the majority of virgins, most of whom later find it no hindrance to fertility. A canal which can be traversed by the passive blood-corpuscle is not impervious to the active spermatozoon. On the other hand, such narrowness of the cervical canal has considerable significance when there is infection of the endometrium or endocervix, as free drainage is thereby prevented.

Broadly speaking, we may say that ninety-five per cent. of sterilities for which the female is responsible are due to three groups of causes: abnormalities of secretion in the cervix and uterine; mechanical damage done to the Fallopian tubes; and defects in the production of sex-cells by the ovary.

A common group of causes is found in one or another type of hostility on the part of the endocervix toward spermatozoa. The cervical secretion is normally alkaline in reaction. It may become acid as the result of fermentative changes secondary to infection, or as a manifestation of a systemic acid diathesis in the absence of infection. Any marked degree of acidity is rapidly fatal to spermatozoa. These facts have been known in a general way for many years. I have occasionally found living spermatozoa post coitum in a cervix acid to litmus, but never in one which was acid to methyl red. This suggests a line of investigation which is now being followed out, to determine the normal reactions of vagina and cervix in accurate terms of hydrogen ion concentration, and the effect of such concentrations on semen.

Apart from the matter of acidity, infections of the endocervix and endometrium have a hostile action on the spermatozoa in two other possible ways. One is the direct biochemic effect of bacteria and their toxic products on the male cells. The other mode of action is mechanical, consisting either of a profuse outward flow of secretion from the uterus, or more often of a plug of inspissated mucus stopping the cervical canal and entangling the spermatozoa.

In the treatment of these endometrial and endocervical infections dilatation and euretteage alone are only occasionally sufficient. The secret of success is the provision for adequate drainage, as in the surgical treatment of infection elsewhere. This is best accomplished, as a rule, by some operation of the Dudley type, which permanently enlarges the cervical canal. At the time of operation and in the course of after-treatment active disinfection of the uterine and cervical cavities should be carried out. When these infections are superimposed on chronic passive congestion of the pelvis, conditions tending to produce this should be corrected. A com-

mon and often overlooked condition of this sort is faulty sexual hygiene.

The commonest single cause of sterility in the female is to be found in old inflammatory damage to the tubes. Most trouble of this sort is the work of the gonococcus, or, less often, of other organisms ascending via the uterus. There are occasional cases, however, where the fimbriated ends of the tubes seal over as a result of low-grade pelvic peritonitis complicating appendicitis. This is common enough to afford an additional reason for not temporizing with subacute or chronic appendix-trouble in young girls.

In the past it has often been very difficult to diagnose tubal occlusion by any means short of exploratory laparotomy. If the acute infection occurred years previously, the history of it is likely to be vague, and pelvic examination may be negative at the time when the patient is seen for sterility.

Two years ago Rubin devised a technique which is very helpful in the investigation of tubal conditions. His procedure consists of the insufflation, under pressure, of gas into the uterus, followed by abdominal x-ray, which will demonstrate a pneumoperitoneum if at least one tube is patent. I have done just over one hundred such insufflations in about forty different patients, and am impressed alike with the usefulness and with the limitations of the method.

The apparatus required is simple. A cylinder of compressed gas is connected to a wash-bottle, in which the visible bubbling serves as an index to the rate of flow. From the wash-bottle leads off a tube which has at its end some sort of nozzle adapted to the external os or to the utero-cervical canal. The pressure of the flowing gas is recorded by a manometer connected to the main channel by a T-piece.

The object is not to produce a massive pneumoperitoneum such as is used in the diagnosis of adhesions or tumors, but merely to demonstrate that some gas does pass into the abdominal cavity. The insufflation of three hundred cubic centimeters is usually sufficient for this purpose. Such a small pneumoperitoneum causes very little discomfort, and so the method is suitable for out-patient or office use. From the diagnostic point of view either oxygen or carbon dioxide may be used equally well. On the ground of more rapid absorption and transient effects the latter gas is preferable.

In the case with normally patent tubes, the gas-pressure at first rises to between fifty and eighty millimeters of mercury, but promptly drops to thirty or forty millimeters as the uterine ends of the tubes are forced open. Almost at once the patient mentions a certain amount of general abdominal discomfort, which she may of her own accord describe as "gas-pain." Such a course of events is quite typical, and may be regarded as definite evidence that a pneumoperitoneum has been produced. This may be confirmed by x-ray, a plate taken after insufflation being compared with a control-plate

taken before. The x-ray should be taken with the head of the table slightly raised; in that position the intra-abdominal gas rises, and even a small collection is demonstrable as a subdiaphragmatic pneumoperitoneum.

When both tubes are occluded, the pressure in the apparatus does not show the typical drop, even though it is raised to one hundred and fifty or two hundred millimeters. No general abdominal discomfort is felt, but some dull pelvic pain may be caused. X-ray will, of course, show no gas in the abdomen.

If a pneumoperitoneum can be thus produced, it is positive proof that at least one tube is patent. No assurance is given that both are open, and nothing is learned by this method about the condition of the eiliated epithelium or the musculature of the patent tube.

If no gas can be insufflated into the abdomen, the presumption is that both tubes are occluded. In one case of mine, however, where insufflation done on three separate occasions failed to produce a pneumoperitoneum, laparotomy showed no organic occlusion, but merely a long mesosalpinx, which had apparently allowed the tube to kink under pressure of the entering gas.

Granting that the fact of occlusion is established, we are still without information as to the location and extent of the tubal damage. Evidence upon these points may be obtained from an x-ray taken after the injection of collargol or other radio-opaque substance.

It has been suggested that the technique just described involves two dangers—the possibility of producing gas-embolism, and the risk of forcing septic material into the peritoneal cavity. With the use of oxygen or carbon dioxide the first danger is remote, as these gases are rapidly taken up by the capillaries if they get into the blood stream. As to the second possibility, there seems to be little likelihood of driving uterine secretions up through the tubes, since only a gentle gas-flow is used. The chronic tubal infections are usually sealed off, and in acute conditions one would naturally not think of using this technique.

Transuterine insufflation was designed primarily as a diagnostic method. As such it has definite value, though care must be exercised in interpreting the results obtained. It has also, I believe, a place in therapeutics, as a post-operative measure for maintaining during the period of healing the patency of tubes upon which a plastic reconstruction has been done.

The ovarian sterilitates form a considerable group, about which our knowledge is as yet very incomplete. Much work remains to be done on what might be termed the minor pathology of the ovary, particularly its functional pathology. It seems certain that abnormal conditions which produce no symptoms of disease may be quite sufficient to prevent normal ovulation. It is of course not possible to study ova as we do spermatozoa, and hence our direct observations along these lines have necessarily been confined to

ovarian conditions found at operation or autopsy. Nevertheless some information can be obtained from a careful history, in combination with rectovaginal-abdominal examination under anaesthesia, this preferably made both during and between periods of menstrual congestion.

The disorders which interfere with the production of normal ova may be grouped under four headings, as constitutional, toxic, endocrine, and mechanical. This is a useful working classification, although in practice some overlapping of the groups often occurs.

Constitutional conditions include malnutrition, anaemia, and cachexia, by whatever cause produced, as well as the results of faulty diet and faulty general hygiene. That such factors have a deleterious effect on the male sex-cells is capable of definite demonstration, and it is reasonable to assume that the female cells may suffer in a similar way. Every stock-breeder knows that poorly nourished and ill-conditioned animals are likely to exhibit lowered fertility, if not absolute sterility. Whether the trouble lies in a diminution in the number of ova produced, or merely in a defect in their capacity for reproduction, the result is the same.

Of toxic conditions which affect the ovary a few examples will suffice. Severe morphinism or alcoholism are known to inhibit both menstruation and ovulation. An occasional sterility has been traced to auto-intoxication from intestinal stasis. The occurrence of absolutely sterile marriages among syphilitics is given by Solomon as twenty-three per cent., as opposed to ten per cent. among the population at large. Whether mumps can affect the germ-cells of the ovary as it occasionally does those of the testis, I do not know. Here again the deficiency may be in the quantity of the ova, in their quality, or in both together.

Endocrine sterilities fall generally into two groups—those cases where complete sexual development has never occurred, and those others who exhibit a premature waning of normal sexual activity. Both states are common; the latter group provides a familiar clinical picture. In it we find the woman who begins to take on weight in her later twenties, to become irregular and scanty in her menstruation, and to lose what little sexual appetite she may once have had. The relation between obesity and sterility has long been noted, but the older writers fell into the error of thinking that the obesity was the cause of sterility, whereas it is really a concomitant result, both arising from a much deeper cause. Organotherapy with whole ovary and thyroid will usually reduce weight somewhat and relieve menopausal symptoms, but it is likely to be disappointing in the treatment of sterility.

Mechanical factors that interfere with ovulation do so mainly by producing an increased intra-ovarian tension, which acts directly to prevent the full development of the Graafian follicle and the discharge of the ovum. When one con-

siders the anatomic vicissitudes through which the female sex-cell passes in the process of maturation, the wonder is that even one oogonium in fifty successful completes that process. Under conditions that are only slightly abnormal that one cell may easily share the fate of the other forty-nine. Thus sterility is often found in patients whose ovaries contain multiple small follicular cysts, or persistent cystic corpora lutea. A thickened tunica albuginea may be responsible in some cases, as may also old inflammatory adhesions. Both dysmenorrhoea and sterility, when due to such conditions, are frequently relieved by a properly chosen operation.

There is a small but definite group of cases where the most painstaking investigation reveals no abnormality in either husband or wife. These are the cases of so-called mismating, incompatibility, or idiopathic sterility. No reason can be found why either party should be sterile, and yet the union is fruitless. It has occasionally happened that such a couple have separated, each has remarried, and each has had children by the new mate. I know of one such case personally. For every one occasion where this sequence has worked itself out and has gone on record, the possibility of it must be present in hundreds of cases. What is the factor which is to be charged up, not against either individual, but against the mating? In connection with blood-grouping we have learned that in two persons picked haphazard there is a fair chance that the serum of one will cytolyse the red blood corpuscles of the other. Insemination is analogous to blood-transfusion in so far as we expect the cells of one individual to live and flourish in an environment of the tissue fluids of another. There is an idea of long standing that the woman absorbs certain elements of the seminal fluid; if that is so, she has surely abundant opportunity to become sensitized against spermatozoa.

I have been much interested in the possibility of a cytolytic factor in sterility, but I hesitate to present this phase of the subject, because my evidence is not yet sufficient to support definitely any conclusions, and so the idea smacks rather of arm-chair reasoning. I have seen five cases which appeared to belong in this class. One of these disappeared from observation, so that four only were completely studied. It was thought at first that a comparison of the blood-groups of a couple might serve as an index of their general serological relation to each other. The data of Moss, however, show that this is not true as regards a possible spermatolysis, since marriages between individuals with hostile blood-groups are as fruitful as other matings. Accordingly, in the four cases just mentioned the wife's blood-serum was tested directly against the seminal fluid of the husband. In two of these cases prompt loss of motility and definite agglutination of the spermatozoa occurred. In the other two no appreciable change was produced in the semen by the addition of the serum. Before any conclusions can be reached on this subject, we must

have a much more extensive series of observations, including controls on non-sterile patients.

As one reviews the literature of sterility, it is a striking fact that large contributions have been made by two groups of people who are not physicians. The first of these are the pure biologists and the second the stock-breeders and veterinarians. We can take certain leaves from the book of each group. Particularly interesting are such observations as those made by Cuénot and by Castle and Little on yellow mice. These mice are an impure strain carrying yellow as a dominant and black as a recessive color-characteristic. According to Mendelian expectations of four offspring from such parents one should be pure black, one pure yellow, and two mixed, these last actually being yellow, since that characteristic is dominant over the recessive black. As a matter of fact, the offspring were correctly proportioned as regarded the pure blacks and the mixed, but the pure yellows never appeared. Little found that these missing offspring actually started to develop, but were invariably blighted at an early period of embryonic life. The reason appears to be that there are certain hereditary qualities capable of transmission according to Mendel's law, which are in their very nature inimical to the development of an embryo which carries them. Such a lethal factor, so called, is associated with these mice with the yellow color-characteristic. Morgan, working on the fly *Drosophila*, has produced a strain of which two members mated together are always sterile, while either a male or a female of the strain in question is fertile if mated with a partner of another strain.

Whether similar lethal factors exist in the human must be a matter of speculation, but their operation might account for an occasional case of apparently inexplicable sterility. Hühner has noted that the parents of his sterile patients had on the average families as large as did other couples of the same station and circumstances. No conclusions can be drawn from such an observation, however, since the majority of his patients were sterile for reasons which had obviously nothing to do with heredity. This phase of the subject is of purely academic interest, for diagnosis cannot be definite, and treatment is out of the question. At least here is a loophole for the unwary medical student who is trapped by the old joke about sterility being hereditary.

In the Bible eight cases of sterility are recorded. In each case it required a divine miracle to bring about a cure. We have improved somewhat in our mortal ability to handle this condition since the days of old, but nevertheless our results, taken as a whole, must be regarded as unsatisfactory. The problem is a complicated one; the solution in each case is well locked up, and the curette is by no means a skeleton key. Improvement in these results will come with a more careful study of individual cases, and a more accurate knowledge of the aetiological factors involved.

AN INSTRUMENT FOR SUCTION, MEDICATION AND MASSAGE OF TONSILS, AND WITH USES IN GENERAL MEDICINE.

JAMES TAYLOR, JR., M.D., WORCESTER, MASS.

SUCTION, medication, and massage of tonsils are rightly taking an important place in the physician's armamentarium.

An instrument to fulfill these forms of treatment must have: (1) The right form to enter the mouth, to act as a tongue depressor, to fit the tonsil, and to hold the application without weakening the air current, or allowing the medicated wool to be lost in the mouth. (2) A trap for secretion. (3) Not only an efficient, but also a mobile force readily controlled, to save pain, discomfort, and laceration of tonsillar and pillar structures. (4) Made of material which is resistant to heat and ordinary usage, and readily sterilized.

In practice these factors have been proved in the present instrument.

First. Remembering that in the movement of a fluid, friction increases with the decreased caliber of its container, the shape of the instrument was so made as to give the maximum of action in its air column when force was applied. For this reason a trumpet form body with wide tubing is used, and shaped to the size of the average tonsil.

Second. Medicated lamb's wool may be inserted, and when the instrument is fitted to tonsil with valve partly or entirely closed, and force is applied, it will bring the medication against the tonsil. On the release of pressure, the wool retreats into chamber. This method may be used when the physician wishes to "flood" the tonsil. Wool saturated with witch hazel solution or cooking soda solution is sufficient.

Third. The trap which prevents infection to bulb and does not interfere with its action. No tissue gives such quick reaction to suction as the tonsil, and a surprise awaits the novice in the amount of secretion which may be drawn from its crypts.

Fourth. Essentially, glass is of primary importance as material in such an instrument. So Pyrex glass is used. This is resistant to heat, readily sterilized, and will stand rough usage.

Fifth. No more efficient and mobile force for operation of this instrument can be found than the bulb and valve suggested in the Boston Medical and Surgical Journal, Vol. 185, No. 13, pp. 381-386.

While this instrument was designed especially for the tonsils, it has many uses in general medicine. It forms a handy and effective method of clearing mucus from throat in anesthesia, pus from wounds, depressed nipples, as a breast pump, etc.

AN INVESTIGATION OF THE RELIABILITY OF LABORATORY TESTS AND A DISCUSSION OF TECHNIQUE OF LABORATORIES IN AND NEAR BOSTON.

(Concluded from page 506.)

By FRANCIS H. SLACK, M.D., BROOKLINE, MASS.

Director, Sias Laboratories, Brookline, Mass.,
Instructor in Public Health Laboratory Methods,
Massachusetts Institute of Technology.

PART 4.

Technique for Health Department Diagnostic Tests.—These notes on technique are simply the expression of opinion of the majority of those engaged in the comparative tests previously reported. Several conferences of these workers were held for discussion of the results obtained and for the adoption of more uniform procedures. No claim is made for originality.

DIPHTHERIA.

Staining.—Loeffler's alkaline methylene blue is recommended for routine work. Slides should be cold and stain applied for not more than one-half minute. Kinyoun's stain is also recommended; slides cold, stain applied two minutes.

Stains: Loeffler's Alkaline Methylene Blue.

Stock sol.: Methylene blue, 1 part; 95 per cent. alcohol, 10 parts.

Stain: Stock sol. 300 c.c. 1-10,000, KOH 1000 c.c.

KINYOUN'S STAIN.

Toluidin Blue	0.5 gr.
Azur II	0.05 gr.
Meth. Blue	0.05 gr.
Alcohol (95%)	25.00 c.c.
Acetic (glacial)	1.00 c.c.
Distilled water to	600.00 c.c.

Dissolve stains in alcohol, add water, add acetic last.

Since some of the laboratories are experimenting with Dr. Albert's stain, the formula is given here, and other laboratories are asked to compare it with the stain in regular use. This applies also to Dr. Kinyoun's stain. It is urged, however, that no new stain, however good, be adopted for routine work until the technician has become thoroughly familiar with it through a long series of comparisons with the stain to which he is accustomed.

ALBERT'S STAIN.

Solution 1.	
Toluidin Blue	0.15 gm.
Methyl green	0.20 gm.
Acetic acid (glacial)	1.00 c.c.
Alcohol (95%)	2.00 c.c.
Water (distilled)	100.00 c.c.

After standing for one day, the solution is filtered and is ready for use.

Solution 2.	
Iodin	2 gm.
Potassium iodid	3 gm.
Water (distilled)	300 c.c.

The solution is ready for use as soon as the iodine is dissolved entirely. The directions given by Dr. Albert are as follows: "Smears are made on slides or cover-glasses; fixed by heat; stained with Solution I for one minute; washed with water; dried with good absorbent filter paper; stained with Solution II for one minute; washed and dried with filter paper. The granules of the diphtheria bacillus are stained black, the bars dark green and the intermediate portions a light green. Virtually all other bacteria also take a light green stain."

Diagnosis.—Except in diagnosis of young cultures diagnosis should be made only on A, C and D types "Wesbrook."

When other of the major forms are present, as A1, A2, B, B1, B2, C1 or C2, but no granules can be demonstrated, a report of "suspicious" should be made and another culture requested. Forms lower in the scale than D may be disregarded. Typical grouping and irregularity of form shall also be considered, but diagnosis should not be made on these points unsupported by the finding of granules. These rules apply also to swab examinations.

In examinations of young cultures the so-called clove-forms with unstained sputum

and without granules are diagnostic.

An assistant should not be permitted to give an independent report on cultures without proven ability and should also have at least six months' training in routine work in a laboratory handling many cultures. For reports on swabs and young cultures the training should extend over at least a year. When two or more diagnosticians are available, reports should be made as agreed upon by two.

Medium.—Loeffler's blood serum. (Horse, beef or pig serum may be used.)

Incubation.—Fourteen or 15 hours at 37° C. is recommended. For the examination of young cultures five hours' incubation or over, the cultures may be removed but should be replaced for the full period of incubation, and examination made again.

Smears.—Smears should be made representative of the whole growth and obtained by rubbing the platinum loop over the whole surface of the serum.

The material thus obtained should be rubbed, with a drop of fresh tap water, in a thin smear over a glass slide, the smear covering an area of at least 1 inch by one-half inch.

A number of such smears on a large glass slide is allowable, provided care is taken to separate the preparations with wax pencil marks and not to allow spattering from one preparation to another.

Cultures which show liquefaction or sufficient contamination to prevent a diagnosis, or which are excessively dry, shall not be considered satisfactory for examination if the result is negative.

Reports.—The reports of the examination shall be:

1. Diphtheria bacilli found.
2. Diphtheria bacilli not found.
3. Culture contains suspicious forms.

When suspicious forms are found a swab preparation shall be examined, if this has not been done. The culture shall also be re-inoculated on fresh media and re-incubated for further study.

4. Culture unsatisfactory, contaminated or dry. In the latter two cases, 3 and 4, another culture shall be requested. Another culture shall also be requested when the result of the examination is negative, if the physician's diagnosis is diphtheria, or if it is stated that the inflammatory reaction is in the larynx.

The organisms associated with Vincent's angina, as found in swab examinations, or the unusual predominance of streptococci either in swabs or culture, shall be reported when found.

If there is a suspicion of Vincent's angina a swab preparation stained deeply with methylene blue shall be made.

Virulence Tests.—Virulence tests on all clinical cases shall be run on request, provided the patient has been quarantined three weeks or over. The State laboratory prefers a period of six weeks' quarantine.

Virulence tests may be made when typical morphological organisms are found and the patient has shown no symptoms of the disease. For the virulence test three or more colonies of the organism shall be isolated and grown in bouillon, + 1 Fuller's seale, for either twenty-four or forty-eight hours. Do not filter. A day's time may frequently be saved in giving a positive virulence report by use of the twenty-four-hour culture. The culture should, however, be further incubated and if the results of the first inoculation are negative after twenty-four hours, a second pig should be inoculated with the forty-eight-hour culture. A control animal inoculated with the same dosage of toxin, but protected with antitoxin, may be used if desired. For dosage use one-half of one per cent. of the body weight of the guinea-pig, injecting subcutaneously in the abdominal wall. Report positive on death of the guinea-pig or if there is any marked inflammatory reaction in twenty-four hours or more and if autopsy shows marked inflammation of the supra-renal capsules. A negative report shall not be made until at least forty-eight hours after the inoculation.

TUBERCULOSIS.

Rules agreed upon are as follows:

Specimens shall be accepted only in outfits provided by the laboratory.

Specimens which have leaked or run over the sides of the container will not be accepted.

Container should have at least one-fourth volume of an efficient disinfectant.

The outside of the container, box, slip, etc., should be disinfected after receipt at the laboratory.

Sputum should be prepared for examination by shaking, digesting with antiformin, or by a combination of both these processes.

Smears should be at least one inch by one-half inch in area.

For staining, Ziehl's carbol-fuchsin is recommended, applied for five minutes steaming; decolorize with alcohol (denatured or 70 per cent. grain) containing 3 per cent. hydrochloric acid. Other accepted decolorizing agents may be used if preferred. Counterstain with methylene blue.

A positive sputum shall be used as a control. The absence of tubercle bacilli shall be reported only after the specimen has been examined for at least five minutes.

A positive diagnosis shall not be made unless at least ten acid-fast bacilli are found, or unless the bacilli are found in two preparations.

Sputum containers shall be used but once and destroyed.

Slides or centrifuge tubes, if used, shall be cleansed by immersion in sulphuric acid and potassium bichromate for at least twenty-four hours before being used again.

In the examination for tubercle bacilli of specimens other than sputum, such as urine or pus, the finding of acid-fast organisms, or their absence, shall not be considered sufficient evidence for diagnosis, but guinea-pig inoculations shall be made.

Guinea-pig inoculations are made by subcutaneous inoculation of the suspected material in the abdominal wall. The animal should be kept six weeks under observation, then chloroformed and autopsied, a positive diagnosis being made on finding the bacilli in the inguinal glands, spleen or other glands or organs. Animals may be autopsied earlier if enlarged glands are present.

Technique, Widal Test.—Specimens of dried blood which are used in making the agglutination test shall be diluted approximately 1-25 with water or physiological salt solution.

A motile culture of the typhoid bacillus in bouillon which agglutinates readily with positive serum shall be used for the test.

This bouillon culture should be made from a stock agar culture which has been attenuated by storage, for about one month, on ice.

The stock agar culture is kept by transplants from agar to agar.

The bouillon culture should be incubated at a temperature between 20° C. and 37° C. for not more than eighteen hours. The culture shall not be disturbed, and only the surface shall be used for the test; or if the growth is too heavy it may be diluted to correspond to a turbidity standard.

One loop of this culture and one loop of the 1-25 dilution of blood are mixed on a cover-

glass, and a hanging-drop preparation is made which should be examined at once, and again after one hour. A hanging-drop of the culture alone should also be made and used as a control.

The diagnosis of typhoid fever shall be made on complete agglutination and loss of motility in one hour. If the reaction is partial, it should be so reported and another specimen requested.

Positive results on specimens from vaccinated persons are unreliable.

Repeated macroscopic tests, for observation of change in the agglutination titre, are recommended for the diagnosis of typhoid fever in those who have been vaccinated.

GONORRHOEA.

Technique.—Smears are stained by Gram's method, and the diagnosis is made on the presence of gram-negative intracellular diplococci of typical shape and grouping in the pus cells.

In chronic cases a positive finding may be made on the presence of typical organisms in shreds or in epithelial cells.

In any case where such organisms are found the report shall be "Gram-negative, intracellular diplococci present."

Stains, Sterling's Method.—Two c.c. anilin oil + 10 c.c. 95 per cent. alcohol. Shake and add 88 c.c. distilled water.

Five grams of gentian violet are ground in a mortar and the anilin solution added slowly while grinding. Filter.

Directions for Staining.—Sterling's solution of gentian violet, cold, one-half to one minute. Wash. Gram's iodine solution, one minute. Wash. Decolorize with alcohol. Wash. Counterstain with bismarck brown, weak carbol-fuchsin, 2 per cent. aqueous pyronin or other weak solution of a contrasting dye.

Carbol Gentian Violet.—Saturated alcoholic solution of gentian violet, 90 c.c. Five per cent. phenol in water, 1000 c.c. This stain keeps well, but is not as permanent as Sterling's.

WEIGERT'S METHYL VIOLET

Solution 1. Absolute Alcohol, 33.

Aniline oil, 9.

Methyl violet in excess.

Solution 2. Saturated aqueous solution of methyl violet.

The staining solution consists of:

Solution 1. 1 part.

Solution 2. 9 parts.

This mixture will keep at the most for four-tenths days.

Barke's Stain (Jour. A. M. A., September 24, 1921). 1. Flood slide with anilin gentian violet or a 1 per cent. solution of aqueous solution of methyl violet. Thoroughly mix with the dye on the slide a few drops, three to eight, depending on the amount of dye, of a 5 per cent. solution of sodium bicarbonate. Allow to stand for two or three minutes.

2. Flush off the excess stain with iodine solution (1 gm. of iodine, 2 gm. of potassium

iodide and 100 c.c. of distilled water) and cover with fresh iodine solution and allow to stand one minute or longer.

3. Wash in water as long as desired and blot off all free water until the surface of the film is practically free of water, but do not allow the film to become dry. The success of the stain depends largely on the proper control of this step.

4. Decolorize with acetone or acetone and ether (one part of ether to from one to three parts of acetone) until the acetone flows from the slide practically uncolored. This usually requires less than ten seconds. The acetone should be placed on the slide. The slide should not be dipped in the decolorizer.

5. Blot dry. The slide quickly dries without blotting.

6. Counterstain for five or ten seconds with a 2 per cent. aqueous solution of safranin O. Exposure to the counterstain can be increased, depending on the excellence of the violet dye used.

7. Wash off excess stain by short exposure to water; blot and dry.

8. Immerse in xylene or turpentine for several minutes, or until clear. Examine.

Technique of Wassermann Test.—For discussion of the Wassermann work as a whole, including all the comparative tests done, it was found difficult to arrange meetings suited to the time of all the participants. Those who were able to be present at these discussions agreed on the use of the technique advised by the State Wassermann Laboratories, using sheep-cells, anti-sheep cell amoceptor and for complement guinea-pig serum.

The reagents are to be prepared and standardized in accordance with the technique of the State Laboratory (*American Journal of Syphilis*, October, 1920).

Minor differences in technique seem to be unavoidable. The exact volume of the test is not important, the majority preferring a volume of 2.1 c.c.

While pooled serums from several guinea-pigs is advised for complement, there is no objection to the use of serum from a single pig, provided it titrates correctly.

It is advisable while complement is out of the ice chest, during the tests, to keep it cold by placing it in an iced receptacle.

It is advised that laboratories using the State antigen control it with at least two others, either two cholesterinized antigens of different strength or one cholesterinized and one acetone insoluble antigen. When an acetone insoluble antigen is used the dosage of serum should be .4 c.c. and a control should be run with an equal amount.

No antigen should be used in quantity exceeding one-fourth of the anticomplementary dosage.

The method of dilution of an antigen is of great importance, and differences in the tech-

nique in this dilution may account for false end-results in the test.

In diluting the State antigen the salt solution should be added through a special pipette, prepared to deliver slowly, until a quantity equal to the amount of antigen has been added, after which the amount necessary to complete the dilution is added as quickly as possible. During the first part of the process the mixture is constantly agitated.

It has been promised that as soon as possible a State antigen will be provided with sufficient antigenic power to allow a larger anticomplementary margin, and that accurate antigen dilution pipettes, with directions for their use, will be furnished each laboratory using the State technique.

In reporting results the following terms shall be used: "Positive," "Negative," "Doubtful," "Unsatisfactory." If desired, a positive report may be further characterized as strongly, moderately or weakly positive. Explanation of an "Unsatisfactory" report may be given as "Anticomplementary," "Hemolysed" or "Bacterially contaminated."

DISCUSSION.

In discussing the whole investigation, the writer wishes to express his appreciation of the cordial coöperation of all the laboratories represented and the great interest shown in the comparative tests. Much would be gained in accuracy by the uniform adoption of standard procedures; that is to say, by an agreement to adopt the best methods.

There is a tendency in any laboratory doing routine work to get into a rut, so to speak, and to lose tone. A series of comparative tests awakens the interest and stirs the worker to a careful observance of his technique. Errors in technique which may have been long unrecognized are revealed and corrected and the conferences of technicians from various laboratories tend to introduce more generally improved technical methods. In the Wassermann work the tests with serums from cases in which the clinical history is compared with the findings has been especially helpful in showing the value of the reactions. Accuracy in laboratory tests is indispensable, and it would be of great benefit in this regard if some arrangement could be made for a constant check or control on diagnostic work, either by the submitting of specimens for comparative tests, by submitting, without the knowledge of the technician, known positives or negatives, or by observing the technique and checking the regular routine.

The smaller laboratories labor under a serious handicap, since they deal with but few specimens, and, because of lack of practice, may make erroneous returns. A false negative on a case of diphtheria or a false positive on a Wassermann may, either one, mean serious trouble. If city laboratories where technicians must pass civil service examinations are not free from

error, what shall be said of private laboratories, which are under no restrictions?

Would it not be a good plan to require that all persons who assume the responsibility of reporting on diagnostic tests should pass an adequate examination and should display certificates in their laboratories?

For oversight of the technique of smaller laboratories and for help in their problems a number of towns and cities might associate in the employment of an expert, or such a person might be engaged by some central authority, and his services given to those laboratories requesting the same; his duties to consist in visiting the various laboratories, observing the technique, advising or suggesting improvements, and checking the diagnoses given, to study new technique and to introduce improved methods, to report any marked inefficiency, and in time of emergency, as in an epidemic, to supplement the work of the regular technicians.

Those engaged in the bacterial examination of milk, which is conceded by most public health authorities to be much more important than the chemical tests, should be required to pass examination before a duly qualified board of examiners and should have their laboratories visited and their technique checked, as is now required for those doing the Babcock test.

Private laboratories offering services in diagnosis tests should also come under sufficient expert supervision to safeguard the public.

The diagnostic laboratory has been of incalculable service, and its importance will increase rather than decrease in the years to come. It is to the advantage of all concerned that all such laboratories be maintained at a high point of efficiency.

CONCLUSIONS.

The best approved methods should be agreed upon and adopted as standards by all diagnostic laboratories.

Those engaged in laboratory diagnostic work should have adequate training and should be of proved ability.

Some method of supervision or of mutual association of diagnosticians should be devised to insure the use of uniform technique and as a control on the accuracy of the work.

BONE SARCOMA: PREVALENCE IN MASSACHUSETTS.

By E. A. CODMAN, M.D., BOSTON.

THIS article is in a measure a continuation of that in the issue of this Journal for August 10, 1922, entitled:—"The Registry of Bone Sarcoma and Medical Human Nature."

Although somewhat less than one-half of the physicians of this State have sent in statements that they do not know of a case of bone sarcoma at present living in Massachusetts, it may be

taken for granted that the great majority of living cases would have been brought to our attention. By checking in the Directory the names of those physicians who have replied we have found the names of those who have not replied and have obtained a fair idea of whether some of the individuals would be likely to know of a case of this disease. We can thus reduce the probability that other cases have escaped our notice. For instance, there are many specialists, many alienists, many doctors doing official work, many virtually retired, etc., whom we can practically cross off the list as negative. In the smaller towns if several physicians replied negatively, we may be fairly sure that no such case is being treated by the other physicians in those towns. Since we know about the cases in most of the large hospitals we may cross off the names of the members of their staffs who have not replied. There are other reasons which it is needless to go into to complete the argument that we think we have let every physician in the State know that we want to hear about every case of Bone Sarcoma, and that we have now located most of the cases.

In the previous article I stated that there were 71 possible cases located. Further investigation has reduced this to only nine, although we have not yet finished our search. If we should include giant-cell tumors, which are still erroneously called sarcomas, there would be at least 22 more.

In other words, the diagnosis of bone sarcoma is frequently made on insufficient evidence. Cases of osteitis fibrosa, syphilis, non-suppurative osteomyelitis, metastatic cancer, myositis ossificans, and ordinary callus are the common causes of confusion. It appears that the diagnosis of a supposed case of bone sarcoma is usually an error and that the patient probably either has a metastatic malignant tumor or a benign disease. Obviously to the individual this is a most important distinction.

There are four practical points brought out by the investigation thus far:

1. That the diagnosis should be made with great caution.

2. That Bloodgood's claim of the benign character of giant-cell tumors (erroneously called sarcoma) is confirmed by experience in Massachusetts.

3. That true osteogenic sarcoma is almost always fatal (the rare exceptions being cases where early amputation is performed).

4. That since only nine living cases could be located in a population of 4,000,000 there are probably only 225 in the whole United States (100,000,000). It certainly is not likely that there are more than double this number at any rate.

This fourth point is of great value to our Committee and will enable us to plan our campaign to study the disease in other States. I wish now to express our sincere thanks to those

who took the trouble to answer the return postal card.

Another point of considerable interest has been brought out. This is the frequency with which amputation has been performed for giant-cell tumor. It should be possible by early diagnosis and complete local excision to save the limb in all such cases. No metastasis need be feared. However, early diagnosis is not an easy matter. Even if the surgeon excises tissue, the pathologist must have had special experience with these tumors and even then is occasionally in doubt. I think that Doctors Mallory, Wright and Wolbach, who have been kind enough to go over the Registry Collection of over 200 cases of supposed sarcoma, will all admit that seeing a large number of these tumors consecutively, has crystallized their ideas of the microscopic appearances so that errors will be less frequent in the future.

Even when the diagnosis of giant-cell tumor is quite certain, there will be found occasions when amputation is the wisest course, for the bone may be destroyed to such an extent as to appear incapable of regeneration sufficient for functional use. This conclusion must be made with caution, however, for it is surprising how in certain cases after x-ray treatment the bone has regenerated.

The Registry has a few cases in which x-ray treatment without help from operation has apparently been effective. It is clear that logically the x-ray may be used in a suspected bone tumor, on the ground that surgery has little chance if the tumor is metastatic or a sarcoma, and delay will do no harm if the lesion is benign. This is perhaps better reasoning than to cut off all the arms and legs on the ground that now and then a life will be saved, for we only know of six five-year cures in the whole United States.

In the individual case these alternatives will continue to present themselves. The Registry Collection is at the disposal of anyone who is confronted by this dilemma. Those who wish to study the Collection so as to be fore-armed should do so before the meeting of the College in October, because after that it is to be sent about to other cities for the opinions of other pathologists.

If there are other cases now in Massachusetts we should be very grateful for their registration.

In order to save trouble for anyone who may wish to notify us of a case, I present the following notes about the cases which are already registered in Massachusetts.

OSTEOGENIC SARCOMAS.

There are only 9 true malignant osteogenic sarcomas now known to be living.

The 1st (Femur), registered by Dr. E. C. Cutler from the Peter Bent Brigham Hospital, has at present metastases in the lungs.

The 2nd (tibia), registered by Dr. J. C. Hubbard, is living and well over 5 years after amputation.

The 3rd, a female of 28, whose thigh was amputated at the Massachusetts General in 1918, has had a recurrence in the stump and the thigh has been re-amputated.

The 4th (fibula), registered by Dr. C. G. Mixer, had an amputation of the leg at the Lynn Hospital in December, 1921.

The 5th (femur), registered by Dr. Robert Slater, refused amputation and is under treatment at the Huntington Hospital with intensive x-ray.

The 6th (humerus), reported by Dr. Anthony of Haverhill, had an amputation of the arm in May, 1922.

The 7th, a male of 38, had an amputation of the femur at the Massachusetts General in November, 1921.

The 8th, a girl of 12, had an amputation of the humerus at the Massachusetts General 2 years ago, and has remained well. There is, however, some doubt as to the pathological diagnosis.

The 9th, was in the mid-humerus in a man of 30. The arm was amputated at the Huntington Hospital in January, 1922.

There was one other doubtful case reported by Dr. E. W. Burt of New Bedford in a woman of 57. In this case we have no evidence that the tumor arose in bone.

It will be seen that with the single exception of Dr. Hubbard's case all are recent ones.

GIANT-CELL TUMORS.

The giant-cell tumor cases known to be living number 22. Twelve of these cases were reported by Greenough, Simmons and Harmer in the *Journal of Orthopedic Surgery*, Vol. 3, No. 11, pages 602-637, November, 1921, from the Massachusetts General and Huntington Clinics. Besides there are the following:

One, reported by Dr. R. W. Lovett, whose arm was amputated for an enormous giant-cell tumor of the ulna in 1908.

One in the humerus was operated on at the Lynn Hospital in February, 1921.

One in the lower end of the radius is registered by Dr. P. D. Wilson.

One in the spine registered by Dr. W. J. Mixer.

One in the tibia, in a woman of 27, was operated on in Worcester and has been registered by Dr. J. E. Goldthwait.

A girl of 15, with a tumor in the lower end of the femur, was operated on in the Mercy Hospital in Springfield in 1920.

One in the lower end of the femur was registered by Dr. H. F. Newhall of Lynn.

One in a finger was registered by Dr. H. J. Maynard.

One in the lower end of the tibia was operated on at the Peter Bent Brigham Hospital in June, 1922.

One in the lower end of the femur has been registered by Dr. J. S. Stone.

We know of a few more giant-cell tumor cases which have not yet been registered. The importance of registering and following up these giant-cell tumor cases is very great, because there are exceptions to all rules, and it may be that metastases may be observed in some of these cases. As yet, however, no case has come to the attention of the Registry which was clearly a giant-cell tumor and has shown metastasis. Local recurrence after incomplete curetting is very common, however.

It is quite as important to register cases which refuse operation and are treated by x-ray, radium, Coley serum, etc., as it is to report operated cases. If a case is being thus treated in good faith as a possible bone sarcoma, it should certainly be registered. Nearly all the above cases have microscopic evidence, but oftentimes good x-rays are nearly as positive as pathologic slides.

POSTMORTEM RADIOGRAPHY.

By JAMES A. HONELL, M.D., BOSTON.

DURING the war, at the U. S. Hospital No. 16, it became a routine procedure to have radiographs made of every patient who died at that institution. The procedure was of inestimable value for instruction and in completing the records of the case. This was especially true in the cases which came to postmortem examination. It was not only of value to the clinician who had, for instance, followed the course of a chronic and complicated case of tuberculosis which perhaps had succumbed to the intervention of an acute disease, but it was of inestimable value in studying the pathology from a radiographic point of view. In this manner a definite check was had on clinical and radiographic diagnosis and the radiograph itself formed a permanent record of the pathology of the case. It also proved of value as regards statistics and research.

During the influenza epidemic of 1918 and 1919 this procedure was of unusual value and the series of radiographs from the very earliest onset of congestion and slight cardiac dilatation to massive pneumonia, substantiated at autopsy, formed one of the most valuable records we had.

At that time I had a series of plate reductions made, so that I had in my possession prints of radiographs, five by seven inches in size, suitable for filing purposes.

Since then it has occurred to me that a procedure similar, but in greater detail, could be applied to the work of the medical examiner. The importance of recording the exact condition of the body as obtained by radiographic means cannot be overestimated. In cases of violent death the presence, size, and exact position of a foreign body, such as a bullet, can be deter-

mined, together with its relation to important structures. It forms a permanent record. As frequently happens in the necessary handling of a body and organs during an autopsy, the foreign body, a bullet for instance, becomes dislodged and much time is lost and unnecessary speculation indulged in to determine its exact previous position. In the case of a wound from a knife or similar object the direction and exact depth can be easily demonstrated. In cases of fracture due to blows by falls or by violence in any form, no better record can be had.

It is often a difficult matter to determine the presence and extent of a fracture, and frequently in determining these fractures by autopsy a tremendous amount of time is consumed. In the case of multiple fractures, sometimes one or more are overlooked. In the case of skull fractures cause and effect can frequently be demonstrated with great exactness. In this manner a large amount of labor would be saved, a record of pronounced value obtained, and corroborative evidence had which the coroner could use with effect in presenting evidence in court in medico-legal cases.

In cases with a questionable cause of death the presence and extent of a disease such as pulmonary tuberculosis or cardiac disease may under certain circumstances be sufficient to modify autopsy procedure. Or, on the other hand, the absence of these conditions or any other demonstrable condition by means of radiography may be sufficient cause for a complete and thorough autopsy.

These records can be made valuable. If the radiographs are reduced by means of photography to such size, say five to seven inches, which is considered sufficiently large for prints to be made from them and which show clearly enough the necessary demonstrable points, then it forms a very complete record of the case. The use of skeleton charts and photography in autopsy work I am perfectly familiar with and I appreciate their value, but it seems to me they can be made additionally complete and valuable by the use of radiography.

A chart is not always convincing to a jury in medico-legal cases but it may be made more so by the use of radiographs.

Here is a field, apart from its more practical aspects, for research that has not been touched and which, to my mind, may give results which cannot as yet be overestimated.

VETERINARY INSPECTION IN NEW YORK CITY.

A Division of Veterinary Inspection has been organized and made effective August 2, 1922, in the Department of Health of New York City.

This Division embraces and controls the veterinary activities of the Bureaus of Preventable Diseases, Foods and Drugs, and Laboratories.

PUBLIC HEALTH LECTURERS FOR THE YEAR 1922.

The Committee on Public Health of the Massachusetts Medical Society has been able during the past three years to arrange with well known specialists in various medical fields to give talks at meetings of the District Medical Societies on subjects of interest and importance to all practitioners. It is a pleasure to announce that a similar arrangement has been made this year and that the gentlemen named below are willing, without expense to the District Society, to give occasional talks of thirty to forty minutes on subjects relating to the promotion of public health, extending opportunity for questions and discussion. It is suggested that medical societies consider meeting at neighboring public institutions, since such meetings have been most successful in the past, particularly at the tuberculosis sanatoria and state hospitals for the insane.

José Pentado Bill, M.D., Doctor of Public Health, Specialty: Preventive Medicine.

Frank C. Dunbar, M.D., Bacteriologist, Instructor in Bacteriology and Pathology, Tufts College Medical School. "Methods of Technique in Collecting Specimens."

Walter E. Fernald, M.D., Superintendent, Massachusetts School for the Feeble-minded.

Timothy Leary, M.D., Professor of Pathology, Tufts College Medical School; Medical Examiner, Suffolk County.

Edwin H. Place, M.D., Physician-in-Chief, South Department, Boston City Hospital. Specialty: Contagious Diseases.

C. Morton Smith, M.D., Chief of Department of Syphilis, Massachusetts General Hospital.

George Gilbert Smith, M.D., Assistant in Department of Genito-Urinary Diseases, Massachusetts General Hospital. Specialty: Genito-Urinary Diseases.

Lesley H. Spooner, M.D., on Staff of Out-Patient Department, Massachusetts General Hospital, Specialty: Specific Diagnosis and Treatment of Pneumonia.

William C. Woodward, M.D., Ex-Health Commissioner, City of Boston.

George H. Wright, D.M.D., Lecturer on Dental Hygiene, Harvard Dental School. Specialty: Dental Surgery.

Thomas F. Kenney, M.D., Director of School Hygiene, City of Worcester. Specialty: Full time School Health Officer.

Secretaries of District Medical Societies writing to ask for these lecturers will kindly designate the topic, the place and the hour of meeting as well as the name of the desired speaker, thus eliminating unnecessary correspondence. Please address communications to the Secretary of the Committee, **Annie Lee Hamilton, M.D.,** 164 Longwood Ave., Boston 17.

THE BOSTON Medical and Surgical Journal

Established in 1828

Published by The Massachusetts Medical Society under the jurisdiction of the following named committee:

For three years WILLIAM H. ROBERT, JR., M.D.
ROGER I. LEE, M.D.
ROBERT B. OSGOOD, M.D.

For two years JAMES S. STONE, M.D.
HORACE D. ARNOLD, M.D.
CHANNING FROTHINGHAM, M.D.

For one year HOMER GAGE, M.D., *Chairman*.
EDWARD C. STREETER, M.D.
EDWARD W. TAYLOR, M.D.

EDITORIAL STAFF.

DAVID L. EDSALL, M.D.
WALTER B. CANNON, M.D.

REID HUNT, M.D.
ROBERT W. LOVETT, M.D.

FRANCIS W. PEARODT, M.D.
JOHN P. SUTHERLAND, M.D.

S. BENY VOLKACH, M.D.
GEORGE R. MINOT, M.D.
FRANK H. LAHEY, M.D.

WALTER P. BOWERS, M.D., *Managing Editor*.
GEORGE G. SMITH, M.D., *Assistant Editor*.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to *The Boston Medical and Surgical Journal*, 126 Massachusetts Ave., Boston, Mass.

THE COUNCIL MEETING.

THE large attendance of councilors at the meeting of October fourth demonstrates the interest of the members, for the temptation to take advantage of a beautiful autumn day for out-of-door recreation must have appealed to many.

Before taking up the business of the meeting the President paid tribute to the memory of Dr. William Andrew Dolan of Fall River, whose sudden death was recently announced. Mention was made of the faithful service in the Council for twenty years rendered by Dr. Dolan and his various professional and civic activities in his community.

The Chair announced the appointment of the following named members of the Committee on the Gorgas Memorial to cooperate with the National Committee: Drs. Frederick C. Shattuck, Samuel B. Woodward, Edmund H. Stevens, Fred B. Lund and William H. Robey, Jr.

Dr. A. P. Merrill of Pittsfield responded to the request for information concerning the annual meeting of the Society, which will be held in Pittsfield next June. He assured the members that the local representatives of the Society, in the western part of the State, are pleased to have this opportunity of providing for the entertainment of the Society, and felt confident that ample accommodations would be available. He spoke of the necessity of having an approxi-

mate estimate of the number of attendants and emphasized the desirability of having responses to a postal card request for information. A very general feeling has been expressed that there will be a large attendance at this meeting, and this plan may add much to the usefulness of the Society. The President added a warm endorsement of this plan. The local Committee of Arrangements consists of Drs. A. P. Merrill, B. W. Paddock, J. B. Thomas, C. H. Richardson and J. A. Sullivan.

The President nominated Dr. C. E. Mongan, Chairman, and Dr. Frederick Irving, Secretary, of the New Section on Obstetrics, and the nominations were confirmed by the Council. Under a resolution previously presented to the Council suggesting holding Council meetings in places other than in Boston at various times, the Secretary reported that he had not secured from the officers of the district societies sufficient endorsement of this suggestion to warrant its adoption.

As requested by the Council last June, the Committee on Public Health reported definitions of the terms "Public Health" and "Public Health Nurse." This brought out an animated discussion by Drs. C. E. Mongan and A. H. Quessy. It was not clearly comprehended whether the remarks were in criticism of the definitions submitted or were intended to amplify and clarify the attitude of the profession toward the common understanding of these terms. Dr. E. F. Cody, of the Committee, seemed to infer that there was a feeling of dissatisfaction with the report submitted, and stoutly maintained that the definitions were clear and comprehensive. The subject is a matter of interest and Dr. Mongan's promise of further discussion will be awaited with interest.

The report of the Committee on Membership and Finance was adopted with a few minor changes. The recommendations for the deprivation of membership for non-payment of dues brought several members to their feet with the promise of personal effort in behalf of some delinquents. The question was raised as to the wisdom of accepting the resignation of a Fellow who had seemed to be guilty of unprofessional conduct, and the recommendation of the Committee was modified by a vote referring the status of a certain Fellow to the Committee on Ethics and Discipline with the request for a definite recommendation.

The Committee appointed for the purpose of canvassing the New England States in order to ascertain the attitude of the other State societies toward the formation of a New England Medical Society reported that there seems to be a strong sentiment in favor of this plan and it was voted to instruct the Committee to continue the functions delegated to it.

According to the opinion rendered by the legal counsel of the Society there is no necessity

of changes in the law relating to authority to hold a larger income, for the statutes permit a latitude in excess of any reasonable expectation for all time.

Dr. H. C. Stetson read the report of the delegates to the House of Delegates of the American Medical Association. The comprehensive statement set forth the important matters considered and merited applause followed its presentation.

The technical details of the meeting will be found in the Secretary's report, which will be published soon. The attention shown and careful consideration of all matters presented demonstrates the quality of service given by the councilors and merits the appreciation of the Society.

THE REGISTRY OF BONE SARCOMAS.

Whether we will it or not, we are obliged to be irritated, amused or instructed, according to our temperaments, by Dr. Codman. Our advice is to be instructed. The persistence which has kept Dr. Codman before us in the columns of the JOURNAL has also been the means of accumulating a unique collection of material, including histological preparations, x-ray plates, gross specimens and case histories of bone tumors from all parts of the country. It has required the same persistence to force this material upon the attention of our leading pathologists in New York, Baltimore and Boston, and to extract from them opinions based upon genuine study.

Valuable progress in the clarification of nomenclature and indications for treatment of bone tumors has already been accomplished from the material now at hand. Information of more scientific value is sure to follow. If Dr. Codman has endeavored to pique us into assisting him, after failure with gentler methods, let us forgive him and reflect upon the service he is rendering at a very great sacrifice of time and energy. Personal knowledge enables the writer of this comment to say that Dr. Codman at first, but only at first, found the expert pathologist almost as reluctant to give his time and thought to the material accumulated as was the practitioner to part with his information and material.

The cases of bone sarcoma already collected by Dr. Codman constitute a larger series than most pathologists see in a lifetime. The collection is to be studied by a group of pathologists and surgeons most qualified for this kind of work, and the results of course given to the medical public. All success to the Registry of Bone Sarcomas!

ANIMAL EXPERIMENTATION AND THE PUBLIC.

It is understood that the Officers of the Suffolk District Medical Society are considering

a meeting open to the public to be held during the autumn in Ford hall on a Sunday afternoon.

The subject proposed is a presentation of what animal experimentation has done for scientific medicine and what medicine in turn has done for the benefit of animals.

For a number of years our medical schools have given lectures open to the public, but it has not been the custom for the medical profession as represented by its societies to hold public meetings in what may be termed an open forum.

The medical profession has in a way held itself rather aloof from contact with the public except through the activities of the various committees which are obliged to deal with matters of public concern. These committees would have their position strengthened by a wider knowledge on the part of the public of medical matters. While the purely technical problems of medicine and surgery are not of public interest, there is every reason why the public should be informed on the broader aspects of those matters which concern medical progress.

It is to be hoped that the meeting proposed will be a success. The interest of the physicians and of the public should be great. If this first meeting compares in interest and attendance with the meetings of the College of Surgeons held in Springfield and Portland, the JOURNAL hopes that not only may other meetings be held in Suffolk but that the other district societies will also hold meetings to present the many topics which intimately concern the public. It is a step toward increasing the influence of the medical profession in civic matters.

AN IMPORTANT MEETING.

On the evening of October 18th, Dr. John O. Polak, Professor of Obstetrics and Gynecology in the Long Island College Hospital, will speak at the Boston Medical Library on Caesarean Section. The meeting will be the first of those to be held by the Suffolk District this season, but at all the meetings physicians interested who are not members of the Suffolk District will be welcomed.

It is almost exactly twenty-five years ago that the late Dr. George Haven performed the first Caesarean Sections to be done in this community, unless we consider the rare cases in which the operation was done on a dying mother in the attempt to save her child. Today the operation is almost commonplace in our suburban hospitals. That the operation is not without risk is shown by the mortality rate of about 10% in one of the best of our private hospitals, open only to a selected group of surgeons. It should be recognized, of course, that this mortality rate is due in part to the condition calling for the operation rather than to the operation itself.

That the indications for the operation are not clearly established is shown by the fact that in

two hospitals situated in neighboring cities of the same general character, the proportion of Caesarean Sections to all births is three-tenths of one per cent. in one and is eighteen per cent. in the other. In other words the proportion of Caesarean Sections is over fifty times as great in one hospital as it is in the other.

Dr. Polak is a man of positive views. His paper and the discussion which it will bring out cannot fail to be of interest and profit. He should be greeted by a large audience.

THE HOSPITAL EXECUTIVE.

Of great importance to the hospital and to the community which it serves is the hospital administrator. A study of the duties and relationships of such an officer has been made by the Committee on the Training of Hospital Executives, appointed at a conference called together in 1920 by the Rockefeller Foundation. The Committee's report points out the importance of the hospital as the meeting place in which come together many and varied interests. The health of communities and of individuals comes in touch, through the hospital, with scientific medicine, with medical research, and with medical education.

Progress in medicine is made available for the patient first of all through the medium of hospitals. The hospital executive, therefore, should be able to appreciate the possibilities of new developments in the technique of medicine and surgery, and should be able to view the matter of community health with a breadth of vision which can only be acquired through previous acquaintance with the problems of public health.

The business aspect of hospital administration, as contrasted with the medical aspect, requires training of an entirely different sort. The capital investment involved in the present hospitals of the United States and Canada probably approximates three billion dollars, with an annual maintenance cost of over half a billion dollars. The value received from the expenditure of this sum depends largely upon the business acumen of the hospital executive.

As a means of providing properly trained hospital executives, the Committee advises the establishment of special university courses. The course suggested would consist of nine months' theoretical training, in which might be given courses on Public Health, Social Sciences, Organization, Hospital Functions and History, Business Science, Institutional Management, Personnel Administration, Community Hospital Needs, the Physical Plant, and Jurisprudence. To this theoretical training should be added four months' practical work in a hospital, and two months spent in visiting various institutions. Opportunity should be given to graduates to do research work along lines connected with some phase of the hospital executive's work.

The value of such a course is self-evident. The benefits derived from it would accrue to the advantage of all those classes in the community in whose lives the hospital plays a part.

"Principles of Hospital Administration and the Training of Hospital Executives."—Report of Committee on Same.

THE SCHOOL FOR THE FEEBLE-MINDED AT WALTHAM.

There are many interesting facts in the last Annual Report of the Massachusetts School for the Feeble-minded at Waltham. At this school some sixteen hundred mentally deficient boys and girls are guarded from the impositions and injuries so often inflicted upon such individuals by their mentally more advanced brethren. They are trained to employ to the fullest extent such intelligence as they possess, and are often taught to perform the more simple tasks of the world in so satisfactory a manner that they are enabled to leave the school and earn a fair living.

By the application of intelligence tests, the mental age of each individual is ascertained, and he is set to work in the grade to which his mental age is adapted. A knowledge of the mental age is of value also in predicting the probable adult mental age of the individual. This prediction is based on the "intelligence quotient," which is found by dividing the mental age by the actual age. Thus a child of eight with a mental age of four has an intelligence quotient of 50%; one of twelve years, with a mental age of eight, has 66 per cent. intelligence. By means of a "Prediction Chart" the final development of each case can be forecast with considerable accuracy.

Most of the feeble-minded can be so trained that they live cheerful and, to a certain degree, useful lives. Dr. Fernald, in his report, speaks of the existence of another class—the defective delinquents—whose management is an entirely different matter. He emphasizes the injustice of having these defective delinquents among the feeble-minded, and points out that although a law providing for their separate maintenance has existed for ten years, it has been ignored. The "good" feeble-minded should be allowed to return to their communities; the "bad," or defective delinquents, should be under life-long supervision at an institution.

That the former class can return to the community with safety is borne out by the studies of Miss Mabel A. Matthews, Head Social Worker at Waverley. She found that of 100 boys allowed to leave the School, most of whom had been out between two and three years, only three had been arrested. Of the others, all but two of the adults had been self-supporting; many of them had bank accounts. The work and the wages of

these boys were studied and classified according to the mental age of each. It is encouraging to realize that so much can be done by society for those whom Nature has treated so hardly.

GASOLINE POISONING.

The United States Public Health Service has published an account of a study relating to the effect of inhaled gasoline on a group of workers employed in cancelling coupons. Each worker was exposed to the liberation of 152.4 minims of gasoline per hour. The maximum amount possible to be inhaled amounted to 36.5 per hour, or 255.4 minims in a 7-hour working day. This amount may not have been inhaled because of variation of air currents, but the nature of the work prevented the use of active ventilation, so that the amount inhaled may have been almost equal to the possible maximum. The gasoline was used in cleaning the belts that fed the coupons into the cancelling machine. The gasoline was kept in open containers within 20 inches of the face of each worker, and had to be applied to the feed belts quite constantly. The report gives the effects of gasoline poisoning found among the workers in the following tables:

Symptoms	Male	Female
Headache.....	4	9
Daily headache.....	4	4
Varying headaches.....	0	5
Drowsiness.....	3	8
Afternoon drowsiness.....	2	3
Dizziness.....	3	5
Heaviness in head.....	1	8
Dull aching pain in eyes.....	2	6
Irritated eyes (burning, smarting, or gritty feeling).....	2	10
Excessive lachrymation (watery eyes).....	1	10
Blurred vision.....	0	3
Puffed eyelids.....	0	1
Slight conjunctivitis, one eye.....	1	1
Slight conjunctivitis, both eyes.....	1	2
Impaired taste.....	0	1
Continued hoarseness.....	0	1
Sore and inflamed throat.....	0	4
Constant irritation of throat (tickling or itching).....	0	2
Constant dryness of throat.....	0	4
Extreme nervousness.....	0	3
Feeling of worry.....	0	3
Easily angered.....	0	5
Often easily excited.....	0	5
Complaint of the work being nerve-racking.....	2	2
Insomnia.....	0	2
Tingling or crawling sensation of the skin of left arm and fingers.....	0	1
Tingling or crawling sensation of skin on right hand and forearm.....	0	1
Complaint of extreme muscular weakness.....	0	1
Extreme tiredness in the morning.....	3	0
Complaint of gradual loss of use of left forearm, wrist and hand.....	0	1
Exhaustion or "all-in" condition by mid-afternoon.....	0	4
Overtiredness at quitting time.....	0	8
Occasional attack of colic.....	0	2

Symptoms	Male	Female
Nausea (in two cases occurred daily, other cases at various times).....	2	3
Loss of appetite.....	1	6
Constipation.....	0	4
Loss of weight.....	0	1
Frequent urination, condition lasting from a few days to four months.....	2	4

In seeking for substitutes it was found that kerosene of high grade colored with alkanet and deodorized with anise oil could be used to advantage, for the dispensary visits decreased in number and efficiency was increased after this change. It was found impracticable to use alcohol because of its greater cost, and also because of the temptation on the part of the employees to abstract quantities for home use.

The employment of gasoline has become so general that the effects following its use present definite medical problems.

NEWS ITEMS.

Dr. George L. Tobey, Jr., and Dr. Harold G. Tobey, have removed to 270 Commonwealth Ave., Boston, between Fairfield and Gloucester Streets.

WEEK'S DEATH RATE IN BOSTON.—During the week ending Sept. 30, 1922, the number of deaths reported was 199 against 198 last year, with a rate of 13.58. There were 48 deaths under one year of age against 36 last year.

The number of cases of principal reportable diseases were: diphtheria, 57; scarlet fever, 15; measles, 34; whooping cough, 41; typhoid fever, 4; tuberculosis, 30.

Included in the above, were the following cases of non-residents: diphtheria, 3; scarlet fever, 2; measles, 1; whooping cough, 1; tuberculosis, 1.

Total deaths from these diseases were: diphtheria, 1; scarlet fever, 1; measles, 1; whooping cough, 9; tuberculosis, 10.

Included in the above, were the following cases of non-residents: diphtheria, 1; whooping cough, 3; tuberculosis, 1.

VISITING SCIENTISTS.—A group of professors from the University of Strasbourg is in this country in response to an invitation from the Rockefeller Foundation. After visiting the Foundation the larger medical schools of the country will be inspected.

THE LOSS OF THE STRATHCONA.—Dr. Grenfell's mission ship after twenty years of service sank October 2nd, 1922, off the coast of Cabot Island. This disaster calls for substantial interest in the work of the mission. Dr. Grenfell is in Europe. He is expected to deliver two lectures in London.

INVITATION TO DR. JOSEPHINE BAKER.—The Medical Section of the League of Nations has invited Dr. Josephine Baker, Director of the Bureau of Child Hygiene, New York City, to become a member and participate in its deliberations.

BEQUEST TO JOHNS HOPKINS.—By the will of Dr. William S. Halsted, lately professor of surgery in the Johns Hopkins University, the residue of his estate, valued at approximately \$100,000, is left to the university, subject to the payment annually to his widow of five per cent. of the value of the legacy. The bequest is to be devoted to research in medicine, preferably in Surgery.—*Science*, Sept 29, 1922.

Miscellany.

SCHICK TOXIN-ANTITOXIN ACTIVITIES OF BOSTON HEALTH DEPARTMENT TO DATE.

The interest shown and the work conducted by the Boston Health Department in preventive measures, relating to diphtheria, merits the gratitude of the people. The good accomplished may never be fully appreciated by the laity but every blessing conferred by preventive medicine adds to the common welfare. If physicians and nurses will supplement the work done by endorsement and explanation of its certain benefits, many more of the people will realize that the best use of public funds lies in the application of efficient methods conducive to the preservation of health.

Encouragement extended to the Health Department and the Associate Council, will bring dividends of health as well as material prosperity. The JOURNAL congratulates the citizens of Boston on the showing made by the Health Department and is pleased to publish the letter of the Commissioner with the detailed statements.

CITY OF BOSTON.

HEALTH DEPARTMENT.

September 28, 1922.

Boston Medical and Surgical Journal:

Your letter has been received with the request for material in connection with the Schick Toxin-Antitoxin activities of this department, and with much pleasure I am enclosing a brief synopsis of the work done from May 6, 1922, to date.

Very truly yours,

F. X. MALONEY,

Health Commissioner.

Closely following the plan originated by Dr. Zingher of New York, conferences were held with the heads of the various private institutions of the city which would provide suitable subjects for the test. At these conferences the value of the test and of the immunization which can be offered to those who show a positive reaction

were minutely explained. Appropriate literature and copies of consent slips were given to the parents of the children of these institutions and on May 6, 1922, the actual work was begun.

Naturally the work began on a small scale, but the numbers have increased in a very gratifying manner. To date the work accomplished is as follows:

	Schick Test.	Read- ings.
St. Gregory's School.....	385	385
St. Vincent's School.....	178	176
East Boston Health Unit.....	1,263	1,181
U. S. Veterans' Hospital No. 41.....	342	334
Children's Hospital.....	55	56
Massachusetts General Hospital.....	106	44
Carney Hospital.....	6,732	5,811
Long Island Hospital.....	106	101
Blossom Street Health Unit.....	1,596	1,377
Daily Industrial School.....	71	71
St. Anthony's School.....	310	309
St. John's School.....	322	322
House of the Angel Guardian.....	674	633
Little Wanderers' Home.....	78	73
Italian Home.....	37	27
New England Peabody Home.....	47	47
Martin Luther Home.....	27	27
Assumption School.....	402	365
St. Mary's School (East Boston).....	490	464
Sacred Heart School.....	556	489
Fittin School.....	486	466
Totals.....	14,256	12,758

The difference between the number of Schick Tests and the number of readings are the absentees. Therefore 90 per cent. of the Schick Tests done by this department have been read.

The various percentages of the reactions are as follows:

Positive	43% (5,276)
Pos. Comb.	6% (690)
Negative	40% (5,135)
Pseudo	11% (1,657)

The positive reactors, 5,276, and the positive combined reactors, 690, totalling 5,966, make up the susceptibles to Diphtheria. Of these reactors approximately 80% have been given the first injection; 65% have been given the second injection, and 57% have been given the third injection, which is generally the required amount for full immunization.

This department has already made arrangements to Schick and immunize 27,000 Parochial School children in the City of Boston and we hope that our results obtainable at these schools will compare favorably with the work done as noted above.

The Schick Toxin-Antitoxin activities are under the direction of the Epidemiologist of this department, Dr. John A. Ceconi. The staff at the beginning consisted of two, one doctor and one nurse, but the work has progressed so rapidly that the Health Commissioner has seen fit to increase the number to nine—six physicians and three nurses, which constitutes the present working personnel. Three more nurses and two more doctors will shortly be added to the present force.

ESSEX NORTH DISTRICT MEDICAL SOCIETY.

THE quarterly meeting of the Society will be held at the State Infirmary, Tewksbury, Mass. (telephone, Lowell 160), upon invitation of the superintendent, J. H. Nichols, M.D., Wednesday, October 18, 1922, at 2 P. M. sharp, and will be a joint meeting with these district societies: Essex South, Middlesex East and Middlesex North.

From 2 to 3.30 P. M. the Infirmary will be inspected and interesting cases will be shown under the supervision of the superintendent and assistants.

At 3.30 the following will speak:

1. J. W. Bartol, M.D., of Boston, president of the Massachusetts Medical Society (15 minutes).

2. C. F. Painter, M.D., of Boston, chairman Standing Committee on Medical Education and Medical Diplomas, upon "The Importance of the Proper Selection of Members of the State Board of Registration in Medicine" (15 minutes).

3. J. S. Stone, M.D., of Boston, secretary Standing Committee on State and National Legislation, upon "Legislative Matters Concerning Hospitals" (15 minutes).

4. W. P. Bowers, M.D., of Clinton, editor of the BOSTON MEDICAL AND SURGICAL JOURNAL (15 minutes).

5. H. Jackson, M.D., of Boston, upon "Diseases of the Myocardium" (20 minutes).

6. J. H. Nichols, M.D., of Tewksbury, "The State Infirmary" (15 minutes).

All the above topics are open to discussion (3 minutes each).

At the close of the speaking, not later than 5.30, dinner will be served.

The next meeting of the censors will be held at Hotel Bartlett, Haverhill (telephone, 8710), Thursday, November 2, at 2 P. M. sharp.

NORFOLK SOUTH DISTRICT MEDICAL SOCIETY.

THE first meeting since May of the Norfolk South District Medical Society was held Thursday, October 5, 1922, at the Norfolk County Hospital, Braintree, Mass., and the Society had as its guest President Bartol of the parent society, who talked on the doings of the Council at their last meeting in Boston. All members present were conducted through the hospital by Dr. Roach, the superintendent, who explained the entire workings of the institution. Dr. N. R. Pillsbury read a very good paper on the "Results in Treatment of Advanced Pulmonary Tuberculosis." Statistics taken from all patients admitted to the hospital since its opening were used in the paper. The meetings of this Society are held the first Thursday of the month at the United States Hotel, Boston.

PHYSICAL EXAMINATION OF SCHOOL CHILDREN.

In an article published in the Health Journal of the Massachusetts Tuberculosis League Dr. William H. Devine reports that practically all attendants in the Boston Public Schools have submitted to an annual examination. Reference to the law is made as follows:

"The law requires that children shall be separately and carefully examined every school year, and a written notice of any defect or disability sent to the parent or guardian. (Physicians are required to complete these physical examinations before December first of each year.) The wisdom of this rule is obvious; it admits of prompt and timely treatment.

"All children are weighed and measured at time of physical examination and record of weight and height is made on physical examination record card. Outside wraps, such as coats, sweaters, etc., are removed before weighing. Children from the kindergarten to the sixth grade, inclusive, are stripped to the waist for physical examination.

"In addition to the regular routine examination the school physician examines as often as necessary all children who require it.

"Physical examinations of girls in High, Latin, and Normal schools are made in the presence of the instructor of physical training, the teacher or the matron. Physical examinations of pupils assigned to open-air classes are made in September and re-examination in February.

"A sealed notification of any defect or disability requiring treatment is sent to the parent or guardian of child.

"Special physical examination of candidates for the Normal School are made by the school physicians in January and June preceding graduation from High School. Report on each examination is sent to the Director of Medical Inspection. Applicants for admission to Normal School may be rejected for any of the following causes:

"Communicable diseases, *e.g.*, tuberculosis

"Defective vision

"Defective hearing

"Epilepsy

"Chorea

"Chronic bronchitis or asthma

"Affections that are:

"(a) unsightly, *e.g.*, chronic skin disease

"(b) offensive in nature, *e.g.*, ozena and allied diseases."

It would be interesting to know how the examination of school children throughout the State compares with the work done in Boston.

UNITED STATES CIVIL SERVICE COMMISSION.

Reports that the entire increase in the number of employees in the Federal executive civil

service, both in the District of Columbia and outside, for the period of six years from June 30, 1916, to June 30, 1922, was 122,806.

Obituary.

FRANK FREMONT-SMITH, M. D.

Word has come of the sudden death in Bangor, Me., of Frank Fremont-Smith, September 29, 1922, at the age of sixty-six. He had been suffering with melancholia, a disease which had affected him some five years ago, and he took his life by cutting his throat.

He was a graduate of the Medical Department of the University of Pennsylvania in 1883, had practiced in Philadelphia and, for the last three years in Boston, having also a summer practice at Bar Harbor and a winter practice in Florida, where he has a residence at Winter Park. He resigned from the Massachusetts Medical Society, February 1, 1922, but retained membership in the Maine Medical Association and in the American Medical Association. He is survived by his widow, a daughter and two sons, who are Dr. Maurice and Dr. Frank Fremont-Smith, Jr., of Boston, both fellows of the Massachusetts Medical Society.

RECENT DEATH.

DR. WILLIAM ANDREW DOLAN died suddenly at his home in Fall River, October 1, 1922, aged 64.

The Massachusetts Medical Society.

MEMBERSHIP CHANGES FOR THE MONTH OF SEPTEMBER, 1922.

OFFICIAL LIST (8TH).

Compiled by the Secretary.

ALPHABETICAL LIST.

Adler, Stuart W., from Boston to Winona, Wisconsin, Winona Clinic.
Alden, Carmi Rupert, Boston, from 645 Beacon to 497 Beacon St.
Barnum, Francis G., Brookline, 85 Abbottsford Road.
Bill, J. Penteado, Wayland, office Boston, now 144 Commonwealth Ave.
Blake, Allen H., West Somerville, from 117 Elm St. to 81 College Ave.
Blanchard, Randall H., Pittsfield, office now 18 Bank Row.
Cheever, Austin W., Boston, office now 270 Commonwealth Ave.
Cheley, Glen E., from Roxbury to Denver, Colo., 538 Imperial Bldg.
Cohen, Samuel Adams, from Boston (Suffolk) to Roxbury (Norfolk), office Boston, 483 Beacon St.
Crittenden, Samuel W., from Woburn to Wakefield, 41 Fairmount Ave.
Cunningham, Thomas D., Denver, Colo., now 1522 Lafayette St.
Dunbar, Francis H., Mansfield, Boston, office now 416 Huntington Ave.
Dunham, Henry B., from Belleville to Verona, N. J., Essex Mountain Sanatorium.
Ehman, William A., Boston, from 154 Richmond St. to 39 Somerset St.

Ellis, Frederic Warren, from Monson (Hampden) to Newton Centre (Middlesex South), 1175 Center St.
Ernst, Harold Clarence, died at Plymouth, September 7, 1922, aged 65.
Fitzgerald, John Joseph, Haverhill, now 83 Emerson St.
Fremont-Smith, Frank, Jr., from Roxbury (Norfolk) to Boston (Suffolk), 205 Beacon St.
Grainger, Frank B., from Boston (Suffolk) to Allston (Middlesex South), office Boston, 520 Beacon St.
Greene, Ransom A., from Boston (Suffolk) to Taunton (Bristol North), Taunton State Hospital.
Greenwood, Allen, Wellesley Hills, office Boston, now 82 Commonwealth Ave.
Howard, Margaret E. P., Reading, 122 Summer St.
Howe, Joseph D., Pittsfield, office now 400 Berkshire Life Bldg.
Keenan, Herbert John, died at South Boston, September 7, 1922, aged 51.
Kleinert, Margaret Noyes, now Boston, 82 Commonwealth Ave.
Koppel, William, Boston, from 82 E. Concord St. to 24 Hancock St.
Korb, Harry, from Roxbury (Norfolk) to New York City (non-resident), U. S. Coastguard Cutter Seneca.
Levine, Samuel A., Brookline, office now Boston, 270 Commonwealth Ave.
Liebman, William, from Hartford, Conn., to Brookline, office Boston, 636 Beacon St.
Little, Abby Noyes, from Syria to Newburyport, 22 Essex St.
Looney, Joseph M., from Somerville (Middlesex South) to Towson, Md., Sheppard & Enoch Pratt Hospital (non-resident list).
Parker, Frederick D., from Brookline (Norfolk) to Chelsea (Suffolk), Soldiers' Home.
Perkins, Franklin H., from Wrentham (Norfolk) to Newton (Middlesex South), 16 Summit St.
Prenn, Joseph, from Worcester (Worcester) to Brookline (Norfolk), office Boston, 536 Commonwealth Ave.
Reid, William D., Boston, now 270 Commonwealth Ave.
Reynolds, Henry Vose, died at Brookline, September 21, 1922, aged 61.
St. Marie, Philippe, Pittsfield, office now 312 North St.
Sever, James Warren, Cambridge, office Boston, now 321 Dartmouth St.
Shattuck, George B., Boston, from 183 to 68 Beacon St.
Slattery, John Richard, died at Auburndale September 11, 1922, aged 55.
Sprague, Russell Bradford, from Suffolk to Barnstable, Yarmouthport, Medical Director Cape Cod Health Bureau.
Story, Theodore L., from Allston to Brighton, 141 Sutherland Road.
Taylor, Erwin H., Pittsfield, office now Agricultural Bank Annex.
Thomes, John B., Pittsfield, office now 18 Bank Row.
Townsend, Charles W., Boston, now 98 Pinckney St.
Walker, Waldo W., West Somerville, office Boston, now 270 Commonwealth Ave.
Webber, Wolfert G., from Brookline (Norfolk) to Newton Highlands (Middlesex South), office Boston, 546 State House.
Weinburg, Philip B., Brockton, now 37 West Elm St.
Weissman, Ruth, from Roxbury to Dorchester, 1027 Blue Hill Avenue.
Woodward, William C., from Brighton to Chicago, Ill., 1535 E. 60th St.

Changes of address should be sent to the Secretary, Dr. Walter L. Burrage, 42 Eliot Street, Jamaica Plain.

Correspondence.

THE TREATMENT OF TUBERCULOSIS.

Mr. Editor:

A prominent physician has written lately that he has "no confidence whatever in any drug treatment of tuberculosis except for the relief of symptoms."

This, to me, is a regrettable statement, and one with which I am not in accord. I am confident, now more than ever, that beechnut creosote treatment, properly given, by the mouth and by inhalation, is curative.

The great difficulty today with many practitioners, is that they do not attend sufficiently, in medication, to facts, which may appear of small importance and yet are often primary. It is essential always, with our most efficient remedies, that they should be given with care and intelligence, back up with experience and, maybe, repeated trial. Creosote has been wrongly given in very many cases. The dose was often too large and not suitably combined. In the majority of cases, it should only be given in relatively small doses, repeated more or less frequently and continued a long while, with occasional interruptions.

If inhalations of creosote are used, they also should be given with much care and attention to little details. Without these, they are not really useful and frequently given up because of the lack of knowledge on the part of the physician. The patient, if improperly directed and guided, will very soon lose faith in the remedy, become discouraged and abandon a very useful treatment, when it is properly carried out. To those who wish to know my views, corroborated by wide experience, I refer them to *Medical Record*, Feb. 27, 1892, and especially to *Medical Record*, Jan. 24, 1920, where they will find not a little that is worth while about "The inhalation treatment in pulmonary tuberculosis."

BEVERLEY ROBINSON, M.D. New York.

[The BOSTON MEDICAL AND SURGICAL JOURNAL, Sept. 28, 1922, page 400.]

CHRISTUS MEDICUS.

Onset, Mass., Sept. 30, 1922.

Mr. Editor:

Your editorial (Sept. 28, p. 485, "The Practice of Medicine by the Clergy") seems to refer to a recent revival, by a Christian, of, what the Church Universal tried thoroughly long ago and abandoned as not within the scope of any powers granted to it. Cumulative evidence of this former practice is given by a late discovery of the earliest inscription yet found invoking Christ's Medians. This came to light in a second Pompeii as to preservation, etc.; in Timgad in Algeria south of Constantine. This city was one of the wonderful African copies of Rome which the French (and the Italians also) have been exploring and describing. This inscription (of about 350 A.D.) is fully explained in a report printed in the *Comptes Rendus de l'Académie des Inscriptions et Belles Lettres de l'Institut de France*, for 1921; citation I unfortunately cannot give, being convalescent from glaucoma operations and away from books and my notes. Christ was then regarded as a healer of physical and psychic ills, evidence of which can be found also in the writings of the African Church-Fathers which are late enough to be familiar to the above mentioned sect which is known to be little interested in mere primitive Christianity. My intended article on the whole subject must be postponed indefinitely, and this letter is merely to call attention to the above report, which can be found in any great library and which will give enough for any ordinary inquirer.

CHAS. ALFRED ELLIS.

NOTICE.

The Suffolk District meeting, Oct. 18th, is open to all physicians who would like to hear Dr. John O. Polak, Professor of Obstetrics and Gynecology, Long Island College Hospital.

SOCIETY MEETINGS.

DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District—Hvannia,—November 3, 1922, February 2, 1923, (Annual Meeting)—May 4, 1923.

Bristol North, Bristol South, Barnstable and Plymouth Districts will hold joint meetings sometime this fall.

Bristol South District—Fall River,—November 2, 1922, May 3, 1923.

Essex North District—Haverhill, (Semi-Annual Meeting)—Jan. 3, 1923. Y. M. C. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Essex North, Essex South, Middlesex North and Middlesex South Districts will hold joint meetings October 18. Place undecided.

Hampden Districts—With Hampshire District in Holyoke. Regular meeting in October.

Suffolk District—Stated Meeting, October 18, 1922. Combined meeting of Boston Medical Library and Suffolk District, November 22, 1922; December 27, 1922; January 31, 1923; February 28, 1923; March 28, 1923; Annual Meeting, April 25, 1923.

The Springfield Academy of Medicine meet the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Hist. The date for each speaker has not been assigned.

Middlesex North District—Meetings Wednesday, October 25, 1922; Wednesday, January 31, 1923.

Worcester District—Union Meeting with the Worcester North District in Fitchburg, Oct. 24.

Worcester District meetings in Worcester, Nov. 8, Dec. 13, 1922, Jan. 10, Feb. 14, March 14, April 11 and May 9, 1923, the last named date being the annual meeting.

The four Western Districts will hold a joint meeting at the Hotel Kimball in Springfield on Oct. 19, 1922.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

Plans are being made for a joint meeting of the Worcester and Worcester North districts in October.

The Fifty-First Annual Meeting of the American Public Health Association will be held at Cleveland, Ohio, October 16-19, 1922. Headquarters will be at Hotel Statler.

The American Association of Oral and Plastic Surgeons will hold their annual meeting at the Medical Library, Boston, on October 20th and 21st.

Clinical Congress of the American College of Surgeons will be held in Boston, Mass., on October 23-27, 1922, Franklin H. Martin, Chicago, Director-General.

Massachusetts Association of Boards of Health, October 26, 1922, Worcester, Mass., W. H. Allen, Mansfield, Mass., Secretary.

New York and New England Association Railway Surgeons, 32nd Annual Meeting at New York City, October 28, 1922, Donald Guthrie, Sayre, Pa., Secretary.

November, 1922. Massachusetts Society of Examining Physicians, (Date and place of meeting undecided), Hilbert F. Day, Secretary, National Cancer Week, November 12 to 18.

December, 1922. New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

January, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston, W. H. Allen, Mansfield, Mass., Secretary.

February, 1923. New England Dermatological Society Meeting, February 14, 1923, at 3.30 P. M., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

March, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary.

April, 1923. New England Dermatological Society Meeting, April 11, 1923, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston, W. H. Allen, Mansfield, Mass., Secretary.

May, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided). American Pediatric Society Meeting, May 31, June 1 and 2, 1923, at French Lick Springs Hotel, French Lick, Ind., H. C. Carpenter, Secretary.

June, 1923. American Medical Association, San Francisco, June 25-29, 1923, Alexander R. Craig, Chicago, Ill., Secretary.

July, 1923. Massachusetts Association of Boards of Health, July 26, Nantasket, W. H. Allen, Mansfield, Mass., Secretary.

*Deceased Sept. 2, 1922.

New England Hospital Association.

ANNUAL MEETING WEDNESDAY, MAY 17, 1922, AT BOSTON MEDICAL LIBRARY.

The meeting was called to order at 10:30 A.M., the President, Dr. Joseph B. Howland, presided.

DR. HOWLAND: It is not my intention to open this convention with a presidential address. We will start with the informal method of meeting from the very beginning, and I should like to say that I think that if this Association is to be a success, it will be because each and all of you take part in it. We plan, at some part of each session,—at the latter part of this one, the one this afternoon, and the one tomorrow morning,—to have a question-box. It was the feeling of the trustees that if this Association was to serve the hospitals of New England to its fullest extent, it would be very largely by giving an opportunity to any of you to ask questions, to be answered by those who have had experiences which enable them to answer them. Outside of the door we have placed a question-box, for this afternoon's session. If any of you, between now and the opening of the afternoon session, think of anything you would like to have brought up at our question-box session, I wish you would drop your question in the box. This morning perhaps we shall just ask questions from the

floor, when we have finished the other business of this session.

On the programme as sent you, the paper by Dr. Hersey, scheduled for tomorrow morning, was down as "The Hospital Kitchen." Dr. Hersey is going to talk on "The Hospital Laundry," instead of the kitchen. It was my mistake in having it so placed in the programme. Also, I want to say, referring to the list of hospitals open for inspection tomorrow, that these visits will be quite informal. They are not going to entertain you, but they are going to try to show you what you may want to see. The list is not complete; the New England Hospital for Women has called our attention to the fact that it is not on our list; they want us to say that they will be glad to have visitors. The Eye and Ear Infirmary will also welcome you, though that is not on our list.

I want to call your attention, also, to the fact that at the small table outside of the door, there is a place for registration. We hope that those of you who have not already registered, will register your name and your hospital.

The order of business calls for the reading of the minutes of the previous convention. As this is the first convention, there is nothing to be said on that. The next item of business is "Announcements." The Secretary has no announcements other than those on the programme.

I will ask for the report of the Secretary.
(Report read by Dr. Faxon.)

Report of the Treasurer was called for and read.

Dr. Howland: Mr. Lee, may I ask that you will get the treasurer's report, and report for the auditing committee later.

The chairman of the membership committee has not arrived; we will have his report later. The chairman of the legislative committee is not present; nor is the chairman of the committee on constitution and rules; so we will proceed with the first paper.

I think we all realize that advances in Electrical Science have been very rapid, and for this reason it seemed very desirable to have a paper on the subject of Modern Hospital Illumination. In asking the speaker of the morning to come, I feel that we are very greatly indebted to him; first, because he is not a member of the Association, and, secondly, because he was due to attend the Convention of Lighting Associations at Atlantic City, which, of course, we all know is a magnet drawing in all very powerfully. He has foregone that convention to come to our convention, and I am sure we are very much indebted to him.—Mr. Alfred J. Hixon, the President of the Hixon Electric Company.

MODERN HOSPITAL ILLUMINATION.

BY ALFRED J. HIXON, PRESIDENT OF THE HIXON ELECTRIC COMPANY.

In addressing you upon the subject of Modern Hospital Illumination, I should wish to correct a possible impression that the laws of illumination were any different in hospitals, than elsewhere. They are not. There are certain specific conditions found in hospitals, which have to be met by special applications, and in so far as these are found exclusively in hospitals they might possibly be called Hospital Illumination. However, Hospital Illumination is no different from other artificial illumination and the best results will be accomplished in every case by a thorough understanding and practical application of the more ordinary conditions and limitations governing lighting. For that reason, I wish first to direct your attention to some of these conditions and will then suggest a few methods of meeting the problems as found in the hospital more specifically.

It is not my intention or desire to attempt to present a learned or technical treatise upon the subject, but merely to point out to you a few simple truths, which may assist you in improving your present lighting systems, and which, if kept in mind, will certainly prevent you from committing many of the common errors with regard to lighting.

The first fact that I want to bring to your attention is that illumination is an exact science. My reason for making this statement is that it is many times looked upon as a "hit or miss" matter, and invariably to the detriment of the results.

The natural laws which apply to illumination, if not fairly thoroughly understood and not properly applied, will defeat any attempt at good lighting. To illustrate, the proper illuminant and proper fixture improperly placed with relation to the area to be illuminated are just as ineffective in the result as would be the installing of an improper illuminant or improper fixture and, by the same token, the improper use of reflectors or glass-ware may defeat an otherwise wholly effective scheme of lighting. It is therefore desirable that in the arrangement of the artificial illumination, first, proper equipment be adopted and, second, that it be properly installed, the object of the comprehensive plan being, maximum amount of useful illumination for the minimum expense, proper consideration to upkeep and operation being given.

The importance of systematic wiring is especially to be noted. By systematic wiring I mean consideration of the proper installation subdivided with a view of maintaining good regulation and sufficient flexibility to enable changes to be made from time to time, without inquiring either the efficiency or the safety of the system. Curtailment of outlets and curtailment of switches for the proper control of lights is invariably expensive in the long run and many times defeats the illuminating system, either from a distribution standpoint or by excessive loss caused from overloading. I merely mention this question of wiring in passing so that it may not be overlooked in your minds. It is a matter which should only be considered by an engineer, since it is a highly technical problem, not possible of solution by laymen.

It should be emphasized that low first cost does not necessarily imply efficiency; the question of efficiency hingeing upon the combination of first cost plus operating expense and upkeep always measured in terms of useful lighting.

The second fact which I wish to bring to your attention is one which I am constrained to believe is a source of more trouble in existing systems than any other one, namely, the disposition on most people's part to perpetuate an existing system, though the same is admittedly in error, the practice dating back to the advent of the incandescent lamp, of substituting one form of illumination for another without due consideration for the improved characteristics of the new illuminant. In the earlier forms of the incandescent lamp this was not so pronounced, but since the advent of the tungsten lamp with its greatly improved efficiency this has become a very serious error. Putting modern lamps in antiquated lighting fixtures and expecting good modern lighting from them, is a fallacy too evident to need more than passing comment. The practice of installing larger lamps in fixtures than the fixtures are designed for, with a view of obtaining greater intensity and better illumination, is equally fallacious.

The third fact that I wish to direct your at-

tion to, is the great improvement made in the type and efficiency of the modern incandescent lamp, which has made possible the entire revision of our ideas and practices with regard to artificial illumination. The early incandescent lamp had an efficiency, and I merely give these figures for comparative purposes, of approximately 4 watts per candle power. The modern so-called Type "C" incandescent lamp has an efficiency of approximately .75 of a watt per candle power, which is something over 5 times as efficient as the original lamp. This, combined with the constantly lowering cost of electricity, especially where bought at wholesale rates, brings the quantity of illumination available at reasonable expense to a point where we have abandoned the idea of specifically lighting certain objects or comparatively small areas, turning to general illumination meaning, filling the area lighted full of light, so that almost any ordinary process may be carried on anywhere in the area without particular regard to the location of the illuminant. This radical change in the approach to artificial lighting has necessitated radical revisions in the ways of measuring illumination and has caused the abandonment of the old candle power ratings and the adoption of the rating of all lamps on the basis of the current consumed and measuring the efficiency of all artificial illumination on the basis of its intensity or, in other words, in foot candles per given area.

The next important fact that I wish to bring to your attention in connection with artificial illumination, is that all illumination is measured by comparison, and I wish to warn you at once against the use of the human eye in making this comparison. The human eye is not a good photometer or foot-candle meter. The reason it is not a good measurer of comparative values in illumination is due to its high degree of what is known as accommodation, and I might point out to you that a large majority of all our so-called eye-strain produced by illumination is produced by this same property of accommodation on the part of the eye and this is due to one of the most common faults in illumination, namely, too great a contrast or too great a degree of difference in light intensity occurring within a comparatively small area or what might be more properly termed, the working area of the eye.

This may be caused either by too brilliant an illuminant, improperly placed, or by the use of the wrong type of equipment such as shades and reflectors. We should strive to avoid marked contrasts in illumination and to obtain the most perfect distribution possible.

An eminent authority on illumination, when recently asked what his definition was of a perfect lighting fixture, stated "that it was a fixture which furnished proper illumination without being unduly conspicuous," or, in other words, furnished the illumination without so great a degree of intrinsic brilliancy as to make itself

objectionable. This, I believe, is the object sought by most of our modern lighting engineers, and most of the modern illuminating units that are worthy of consideration embody these features in a more or less successful manner; it therefore remains for the engineer to give due consideration to the nature of the area to be illuminated and the use to which this area is to be put, to select and install the proper lighting.

I wish to impress upon you that all artificial illumination should be measured in foot candles of useful light at the working plane and not in fixture ratings, and that all fixtures and equipment should be purchased rather with the thought of economy of operation than economy of first cost, since cheap glass-ware may defeat a lighting system to such an extent that the original cost of the fixtures may be consumed many times in the coal pile and thereby prove very expensive.

For the purpose of measuring foot candles of useful light in any given area, which, really in the last analysis, is the measuring of the value received for the money spent, I wish to call your attention to this little instrument known as the Foot Candle Meter, which is one of our more modern products and which I commend to you for its simplicity, its accuracy and its freedom from any technicalities. It can be used by anyone without the slightest technical knowledge and with the most effective results. Every institution which considers its running expense and wishes to enhance its lighting efficiency should own one of these little instruments, and the executives of the institution should satisfy themselves by its use, that they are getting what is best for them in the way of artificial illumination. I venture to say that the general and intelligent use of this instrument, combined with the little expert advice as to improving methods and equipment, will effect a marked saving in 99% of the hospitals of this country.

To sum up the foregoing rather brief résumé of what might be called the cardinal points of artificial illumination:—

1. Lighting is an exact science.
2. Efficient lighting requires coördination of equipment, lamps, fixtures, and wiring.
3. Modern lighting is done largely by general illumination.
4. The two prime factors to be considered in lighting any given area are, intrinsic brilliancy of the illuminant and equal distribution in the area illuminated.
5. Measure artificial illumination in terms of useful light rather than in fixture or lamp ratings.

In the illumination of the sick-room, whether it be the open ward or the private room, up to a certain hour in the evening when the patients are supposed to go to sleep, we should closely simulate the home under normal conditions. This should be a cheerful illumination which requires a brilliancy of from 3 to 5 foot candles.

It is essential that this illumination should be by means of a type of illuminant in which the intrinsic brilliancy, or contrast, should be very low owing to the fact that the patient is in a reclining position and therefore forced to face the general direction of illumination. This fact does not justify the placing of the illumination in abnormal positions such as from the floor, but merely means that the illumination must be sufficiently distributed to avoid high brilliancy or marked contrast.

After the hour in the evening when the principal illumination is extinguished and the patients are supposed to go to sleep, the rooms must be provided with sufficient lighting to enable the nurse to make her rounds without inconvenience or undue disturbance. This illumination must not be sufficient to wake the sleeping patients and should not exceed $\frac{1}{2}$ of 1 foot candle. Since unusual lights have a marked effect in waking the patients, it is found desirable to have this second source of illumination in the same location as the principal illumination for the room, this also giving the desired distribution.

We have worked out a fixture for this purpose to which I wish to direct your attention. We do not claim that this is perfect nor that it is the only solution, but we feel that it is one reasonable solution of this very vital problem. I am quite certain that any solutions which depart from the elemental essentials of good lighting to accomplish these results are wrong.

Bed-side lamps of normal brilliancy, no matter how shaded or hooded, do not serve the required purpose because of two very prominent reasons: One, they will not sufficiently illuminate the room to give the nurse convenient freedom of action; two, they produce the contrast that should be avoided. Lights in the floor and other unusual places are not successful as long as they do not provide two intensities of illumination.

A special application of great importance in a hospital is the illumination of the operating-room. I would call to your attention the large majority of forms of illumination commonly used which center the light upon the object. This is wrong. The problem in the operating-room is the same problem it is elsewhere; namely, filling the area full of useful light, so uniformly distributed that the eye will not be called upon to accommodate unduly and the hand and the instrument will not cast prohibitive shadows. This can be accomplished merely by installing a suitable type and arrangement of ceiling fixtures, taking into consideration the necessity for a much higher degree of intensity and better distribution of illumination than is required elsewhere, from 25 to 50 foot candles over the entire working area.

There are other minor special applications for hospital illumination, but the two that I have here pointed out are, I find, the principal deviations which might be directly termed Hospital Illumination. In the remainder of the hospital,

the same rules for good lighting should be applied as are applied in an office building, bank, factory or any other place where the people are doing more or less confining work and should be applied to the types of utility that are found in the various parts of the institution. The question as to proper amount or degree of illumination is, to some extent, fairly well established, such as where clerical work is being done the light on the lighting plane should have an intensity of from 5 to 8 foot candles. In dining-rooms, kitchens and other places where the work is less confining this illumination can be cut down to 4 or 5 foot candles.

It is well, as a general principle, to avoid so far as possible specific lighting such as reading lamps, desk lamps or lamps directly over machines or tables, general illumination being much safer and much better for the person doing the work, as well as producing much better work.

Electric lighting fixtures have been made a subject of special consideration for hospitals to such an extent that it has produced in the minds of many people the idea that there is something different about hospital lighting and hospital fixtures than about the ordinary commercial lighting and commercial fixtures. This, I believe, is an error, or at least a misconception. I realize the necessity in hospitals of having everything free from dirt and, to accomplish this end, easily cleanable. I am also of the opinion that all electric fixtures, whether in hospitals or elsewhere, should be of such rugged and substantial construction that they will be fairly free from unreasonable depreciation. In the attempt, however, to accomplish these two very practical requirements, nothing should be done which decaats or interferes with the principles of lighting. A good illustration of what I have in mind is the use of clear cover-glasses; the assumption on the part of most people is that this does not interfere with the lighting. It would probably be considerable of a shock to many of you to know that as high as 25% of the light is in some cases absorbed by this cover-glass, where the glass is of cheap or inefficient make. I could go on indefinitely pointing out similar conditions and failures of equipment due to one misconception or another, but this will serve to illustrate my point.

DISCUSSION ON MR. HIXON'S PAPER.

DR. HOWLAND: I think you will recognize that Mr. Hixon has gone to no little trouble in bringing his own office force here and setting up this installation, because he is very much interested in efficient lighting problems. I knew of his intense interest, and that is why I asked him to give us this most valuable paper.

We are very much accustomed to the remark, that it is not the first cost of an automobile, but the cost of upkeep that counts; now I think, if we have taken home the lessons Mr. Hixon has given us today, we recognize that we have a very

similar situation in our hospitals in regard to lighting. I doubt if there is one out of ten of our hospitals that doesn't come into this class, in that we are running along with very inefficient, out-of-date lighting apparatus, and are constantly spending money to bring it up to standard. We know, if we have to spend money on new lamps or fixtures, that it is going to cost something, but we do not recognize it clearly when it comes in the coal bill.

Mr. Hixon calls attention to the modern type of lamp; the so-called nitrogen lamp is five times as efficient as the old carbon lamp, and three times as efficient as the lamps around the room, which most of us use to a very considerable extent.

MR. STEVENS: I am extremely interested in Mr. Hixon's talk. It is very enlightening; I had almost said very illuminating. It has given me many good suggestions. There are one or two things which in my own practice I have brought out in lighting. We always try to get our inspiration wherever we can, and in going through one of the larger hospitals in Europe, I noticed that they had the double lighting system Mr. Hixon speaks of, the intense lighting for illumination of the room, and the night light; and the night light I noticed was made less actinic by being dipped in blue, giving a less trying light, a bluish light. I have since used that a number of times, with very good effect. Dipping the bulbs in amber gives even a softer light. This is just a suggestion that I have worked out.

Another thing that occurred to me, which Mr. Hixon did not mention, is the matter of night lighting of the corridors. I have met with considerable reaction from the fact that corridor lights,—which we must have,—if the doors of the patients' rooms happen to be open, or there are transoms, are rather trying to the patients' eyes; and to overcome that I have placed lights low down in the wall. These lights give sufficient illumination for going about the corridors, and do not interfere with the patients' comfort. The same thing applies in the operating-rooms. While we must have the intense light for certain times, there are other times, such as when the nurses are cleaning up the room, that the intense light is not needed; and side lights of a nature similar to those placed in the corridors have been placed in operating-rooms to advantage.

MR. HIXON: Dipping the lamps in blue does not reduce their actinism; it increases it, because the blue filters out red rays. A blue glass lamp, easily obtainable anywhere, is made for the purpose of taking out the red rays. A blue light is much easier on the eyes than a red light or a white light. The non-actinic ray is the ray which has the weakening and disturbing effect. Amber light is the proper light. On any of these

fixtures here, you find an amber light. There are various possibilities; but the only really satisfactory way we have ever found of accomplishing this purpose is by having two different intensities. On the question of lighting corridors, we simply have taken this position,—if the corridor is lighted by clear glass in the doors of rooms, or by transoms, then the same thing applies to the corridor that applies to the room, and you use the same type of fixtures, or something akin to it. The question of having lights in corridors specially placed in the walls, is about the same as using lights in floors, and I should say that the best statement to illustrate the fallacy of those things,—though I say it reservedly,—is to note the fact that natural illumination comes, ordinarily, from above, being reflected by the ceiling. You know that this room is not well-lighted, partly because the fixtures here are not right, but mainly because the nature of the ceiling is such that it cannot be well lighted. The only kind of fixture that would light this room well would be a fixture that had a reflector over it. Normal light, natural illumination, comes from above; it comes in the windows, and is reflected from above. When you put lights below, you produce sharp shadows, no matter what intensity it is, which gives a marked contrast between the intensity of light at one point and at another point, and these contrasts are what give most of the trouble. You want even distribution; I think of the many things necessary to produce good light, distribution is the main thing. Natural illumination is the best illustration of distribution, and the reason is because the sun is so far away. If it were possible in artificial lighting to place the illuminant at great distance from the surface to be illuminated, then we should get distribution. While I do not say there is no way of working out the side light proposition, I am of the opinion that the tendency should be away from these things, rather than towards them. The same thing applies in regard to the operating-room. There should be lights of greater and lights of less intensity. What I have tried to fix in your mind is that the illumination should be distributed, and sharp contrasts avoided. You should have absolutely uniform illumination over the entire working area; not only on the patient who is being operated on, but on everything in the room.

At the present time, we can produce lamps known as daylight lamps, and we are proposing to install in one or two hospitals an experimental system, in the operating-rooms, of the reproduction of daylight intensities; that is, the reproduction of the intensity of daylight, of the distribution of daylight, and of the color of daylight. You have all, probably, experienced the difference between artificial daylight and daylight. Under artificial daylight, the colors seem to be sometimes brown and sometimes blue; they change like a kaleidoscope. Light can be pro-

duced which will supersede artificial light, and give the same intensity and the same quality as daylight, and that is what we are attempting to do.

Dr. Carrell of the Rockefeller Institute has installed a system of daylight lamps. He had at first a combination of skylights and these lamps; now he keeps the skylights closed and works entirely by the lamps. He says illumination by the lamps is so much steadier, and so much more uniform that he prefers it to daylight; because when he uses daylight, he gets in the middle of an operation, when perhaps a cloud goes over the sun, and the intensity of the light changes. So he prefers artificial light. When we can reproduce daylight in color and with sufficient intensity, and sufficient distribution, we shall find artificial light superseding daylight for these purposes.

An explanation of the color scheme of Dr. Carrell was asked for.

MR. HIXON: Dr. Carrell is very much opposed to all whites. His room is done in dark lead color; the ceiling is not so dark as the walls; the floor is quite dark. In other words, the room is such that the walls do not reflect. That is one of the things that cause much trouble. Light goes to the wall and back to the object, and you get different angles, which cause reflections and which obstruct vision. Dr. Carrell does away with that by having everything dark color. His clothes are all dark colored. None of his nurses or attendants dresses in white; so that there is no reflection whatever. It is all absorption, rather than reflection. His lighting scheme consists of groups of lamps within four or five feet of each other, so arranged that the light comes from so many sources that there are no shadows. The room is almost entirely free from shadows. There are no cross lights, because there is no reflection. Doing away with the skylight, he has uniformity of illumination at all times.

DR. BAKER of Fitchburg: What do you consider the best color for the walls of an operating-room?

MR. HIXON: I hesitate to make an absolute statement on that matter. I don't believe any walls in any hospital should ever be painted white or any of the very light tints. That has been done simply to conserve a meagre supply of illumination, and it has produced glare and many trying effects. In an operating-room, I don't know whether I would go as far as Dr. Carrell does, to say that the room should be always like a dungeon. I think it should be a great way from light colors,—surely not white. For the conservation of light, white is the best, a non-absorbing white.

DR. BAKER: As a lighting engineer, what color would you put on the walls of an operating-room?

MR. HIXON: Light gray,—or perhaps not a light gray, but a quite pronounced gray; with the ceiling about the same, and the floor somewhat darker.

DR. BAKER: What size candle meter should the ordinary living room register in order to be well lighted?

MR. HIXON: A room to be cheerfully lighted should have from 3 to 5-foot candles, depending upon the surroundings, such as the color of the woodwork, the painting, hangings, the amount of them, and so on. A very dark room should have as much as five; a lighter one, with lesser hangings, may be equally well illuminated with 3-foot candles. For a well-lighted room 3 to 5-foot candles are required. If it is much below that, you get eye-strain from the attempt to see; there is an excessive accommodation; or if it is much above that, there will be eye-strain, because of the relation between the minimum and the maximum light and from the nature of the light.

Q. In a single bedroom, private room, where should the electric lighting fixture be placed?

MR. HIXON: The fixture should always be placed in the ceiling. It is impossible to get proper distribution from a fixture placed in the side wall.

DR. PETERS, Rhode Island Hospital: What is the best way to illuminate an operating-room—from a special hanging lantern and reflector, or lights around the edge of the ceiling, or from lights over glass ceilings, or from several openings in the ceiling?

MR. HIXON: That depends somewhat upon the nature of the room, and also upon the height of the ceiling. Taking a room of average size, with a full-size operating table, and the usual number of surrounding tables, and the usual number of people working, I should say that the best method of illumination would be six or eight fixtures hanging from the ceiling; depending somewhat on the shape of the room. Reflectors should not be used. They project light, and any attempt to project light kills distribution, and whatever kills distribution produces sharp shadows, which defeats illumination. You want to control the light and distribute it, so that the light in one place is as great as in another. The nature of the light should be such that it will work the same as daylight, and produce the same color reaction as daylight, for the reason that the eye normally works under daylight more than under artificial light. If you can simulate daylight, you get the most efficient condition, and that is what you should do. You do not want any reflectors, for anything that tends to project light is bad. You want something that distributes it, and just simply directs it, and conserves it, to the best advantage.

Dr. FAXON, Massachusetts General: The problem of lighting desks in an office room, either in the superintendent's office, or the clerks' office, comes up frequently,—should that be done from an overhead fixture, or from a desk lamp?

Mr. HIXON: In answering that question, I seem to have to qualify my other statements. If you have a room that is strictly an office room, a room where there are two or three persons working,—say a room 15 feet square with a 10-foot ceiling,—the most efficient and the best way is to fill the room full of light by illumination from the ceiling. In other words, simulate, as well as possible, daylight conditions. But I know a number of cases where a desk is placed in a large entrance rotunda, and where the total illumination is not sufficient. Under those conditions, the best thing to do is to have a desk light of special illumination. But as far as possible, avoid desk lights, or the lighting of specific areas. In insurance offices a large number of clerks are usually employed; sometimes hundreds work in one room. A few years ago, it was a quite common practice to have a light on every desk, and anyone who didn't have one felt slighted. When general illumination from the ceiling was put in, they were very reluctant to give up the desk lights, the individual illumination. It took quite a while to realize that those desk lights were very disturbing to the eye-sight. Most eye-strain comes from lack of uniformity, from poor distribution. If you get good distribution over the working area, you are saved from eye-strain. There are specific cases where you might want a desk fixture; but in the usual case, general illumination makes the room more cheerful, produces better work, conserves the health and eye-sight of the person doing the work.

Q. I have heard it stated that one insurance company that installed the system you speak of, later on found they were having difficulty with eye-strain; do you know about it?

Mr. HIXON: I will say this, that this whole matter of general illumination is only just in its beginning. Some of the earlier attempts were defeated, some because the illumination was not sufficient,—and just the condition you speak of took place. Other cases were defeated because the wrong fixture was used; in other cases the fixture was right, but the distribution was wrong—wrong arrangements of fixtures. What I would say is, that it is perfectly possible to give a room general illumination in such a way that you will practically do away with eye-strain, and increase production. I do not mean that everything that looks like general illumination immediately accomplishes these things.

(At the request of Dr. Hersey, New Haven Hospital, Mr. Hixon demonstrated the difference between carbon light and tungsten light).

Dr. FULLER, Fall River Municipal Hospital: What is the relation between the size of a room and the distance of the fixture from the ceiling?

Mr. HIXON: That depends upon what is known as the working plane. You have first to establish where the working plane is located in the room and what amount of illumination is desired on this plane. The location of the illuminant then depends upon the intensity or size of the lamp. This is restricted only by the possibly intrinsic brilliancy which can be used without producing eye-strain.

Having determined the size of the lamp and the intensity required at the working plane, the location of the lamp depends upon the height of the ceiling, which limits the height of the lamp above the working plane.

When these factors are all taken into consideration the spacings of the fixtures can be worked out exactly, so as to give very nearly uniform illumination. The neglect of any one of these factors in working out this illumination problem will certainly defeat the result, and this is the most common reason for bad lighting and unsatisfactory results.

Dr. HOWLAND: I just want to say that Mr. Hixon has been given an opportunity to put in what he thinks is the right operating-room lighting fixture in a hospital not yet completed, and I hope it will be something that you will be interested to come and see later. I think we have all made mistakes in corridor lights. We have put in glass transoms, and then had to cover the transoms, because the lights disturbed the patients at night, and perhaps we have been tempted to do what Mr. Stevens spoke of,—put bracket lights down below the transoms. One very simple thing to consider is whether you have transoms for light, or for ventilation. If for ventilation, it is very easy to put in something opaque. It is also possible, without going into the matter very deeply, to consider the location of night lamps, and not have them placed opposite the doors of the rooms.

If there are no other questions, I am sure I am speaking for all of us when I say that we appreciate very greatly Mr. Hixon's coming here and giving us so much time and telling us so much.

I did not know just how to plan the programme; I did not know just how much time would be taken with the reports and discussions. So far as the schedule of papers is concerned, we are through for the morning, and I hope now we may have some questions from the floor.

AMBULANCE SERVICE.

Dr. HERSEY: I should like to inquire if any of the hospitals are able to get on without ambulance service by employment of outside agencies to carry patients back and forth.

Dr. BAKER, Fitchburg: We do that. One of the garages maintains a public ambulance, and

they bring in all of our cases. We pay them \$3 for every ward case, and \$5 for every private case. They never send out an ambulance to bring a patient to the hospital until an order is given from the hospital. We get along quite smoothly that way.

Q. How much does it cost a year? **A.** About \$100 to \$125 a month. We average about 100 patients a day. They handle emergency cases, and their service is very satisfactory.

Q. Do you call for private cases? **A.** We do call for private cases and pay the garage.

MR. PORTER, Malden: Why should a hospital provide an ambulance, or when? At what stage in a hospital's development should it provide an ambulance?

DR. DREW, Worcester City Hospital: The Police Department of Worcester provides ambulance service for all the hospitals of Worcester. I don't know that any hospital in Worcester maintains an ambulance service. There are private ambulances, and I think the Police Department charges patients who are admitted to the private ward service, and, possibly, they make a charge for some other patients; but the City Hospital does not collect any fee, nor pay the ambulance people for any work they do. If a ward patient wants to go home, the Police Department takes him home when we request it. Usually they wait until the ambulance has to bring a patient to the hospital, and probably then another patient will want to go home, and is not quite able to go by trolley, and perhaps not able to pay a taxicab.

DR. HOWLAND: Do patients not object to having the police ambulance come to their doors?

DR. DREW: They are so used to seeing the ambulance take patients, they don't object.

MISS METCALF, Lewiston, Maine: In Lewiston the undertakers maintain an ambulance, which is at the service of the public. The hospital I represent serves a community within a radius of 50 miles. It is a very common occurrence for a doctor to ask to have the ambulance at the train to meet a patient. We call the undertaker and engage the ambulance, and the patient pays the bills, which is usually \$3. They also go long distances into the country to get patients, and to take them home. The undertakers have to keep men around for their work, and these men are very expert in moving patients. They are frequently called in accident cases. The charge is \$3 for going to the station; for trips out of town, it varies. We have a cot, which they furnish a very comfortable bed, which can be hired to send the patient on the train. Many patients come on the Grand Trunk Railroad, from as far as Portland. They furnish a comfortable cot, with a little mattress on it.

MAN. I think, Mr. Chairman, that if people object to having the police ambulance call at their doors, they would object more to having the undertaker call.

MISS METCALF: They use a special ambulance; not the undertaker's wagon.

WOMAN. We use the undertaker's wagon, but it has a red cross conspicuously placed on it.

MISS LEECH, Somerville Hospital: Our Police Court does all of our ambulance work, entirely without charge either to the patient or the hospital. They not only bring and take away the house cases, but patients for x-rays.

DR. FULLER, Fall River Hospital: We have a free ambulance which takes all patients, for x-rays, orthopedics, and so on. The only restriction is that the ambulance does not go outside of city limits.

Q. On what basis do you charge in Lewiston, Miss Metcalf?

MISS METCALF: I don't know how much it is for long trips. It makes some difference if it is in the night, and it also depends on the time of year, the condition of the roads. The average city cost is about \$3.

DR. HERSEY: We maintain our own ambulance, and charge one dollar a mile in one direction.

DR. HOWLAND: The Peter Bent Brigham charges \$1.50 a mile.

DR. J. M. PETERS, Rhode Island Hospital, Providence: Within city limits, we charge \$2 a trip, no matter what the distance, if they are able to pay. Outside the city limits, the minimum charge is \$5, a dollar a mile after they leave the city; that is, if it's a mile out from the city, the charge is \$6.

DR. CANN, Union Hospital, Fall River: We maintain a private ambulance service, and charge \$1.50 within city limits to private and ward patients, and \$1 a mile outside of the city limits, in one direction; we do not charge for the return trip.

REFRIGERATING SYSTEMS.

DR. RICHARDSON, City Hospital, Providence: I should like to ask whether other hospitals have difficulty in maintaining different temperatures in their refrigerating boxes, one box being, say 32°, and another 40°.

DR. FAXON, Massachusetts General: I don't think this will help very much; but a year or two years ago, we installed a new refrigerating system, and following the installation we had a lot of trouble in maintaining temperatures, not only in different boxes, but in the same box. The

trouble was finally traced, and, after many trials, was found to rest mainly with the machinery itself. The installation was not well done. Since those defects have been remedied, we have had no difficulty. So it would seem that the problem came down to a proper engineering plant, and to installation properly placed. Those two factors being settled, it ought to work all right. Our trouble was in the mechanical operation of the plant; that being remedied, it worked all right.

DR. HOWLAND: We found difficulty in the cooling box due to the manner in which the piping was placed. Air-traps had to be put on at the highest part. Otherwise, it didn't circulate well.

DR. RICHARDSON: We had a plant put in just recently. While it works pretty well, it doesn't work exactly as I hoped it would. It was put in by the automatic people, and in their system the automatic arrangements work from a key-box, which is farthest from the machine, and when that box gets to a certain temperature, it starts the machinery. The other boxes must be so bypassed as to coincide with that key-box; that is, if the key-box goes below a certain temperature, it should be maintained by the other boxes through the by-pass. I think we have more or less difficulty.

DR. FAXON: Ours works by the coöperation of the store man, who is in charge of the ice-box, and the engineer. That is the automatic method we pursue. I think it is more trustworthy than yours, Dr. Richardson.

NURSES.

DR. SMITH, Maine General Hospital: At a meeting of the Hospital Round Table last January, I proposed a question which my friend Dr. Peters somewhat flippantly called a conundrum; but I am going to introduce it again today, hoping that with the large experience of those here, I may get some light. The question is this: Can anyone offer a practical solution of the difficulty many of us are having in keeping up our supply of probationer-nurses? If I may be allowed to say just a word,—doubtless many of you will agree with me that for the past few years there has been increasing difficulty in making good our losses by graduation, by an adequate supply of probationers. One reason, I am quite sure, in my own State, is that we have a large number of very small hospitals, running from fifteen to twenty-five beds, and every one of those small hospitals seems to think they must maintain a training school, and a great many young women are directed to them who would otherwise go to the larger general hospitals. Another phase of the question impresses me somewhat. There is not only an increasing difficulty for the hospital training schools to keep up the supply of nurses, but the

supply of those who ought to be utilized for the public is being diminished by the fact that public health work, various philanthropic services, schools, insurance companies, and others are taking graduate nurses out of the field of private work and employing them in semi-public and official positions. It seems to me that is one phase of the question that has not hitherto asserted itself quite as much as at present. We are feeling it in Portland, and probably other parts of Maine, very keenly.

MISS RIDDLE, Newton Hospital: I believe that the training school should, first of all, have something very definite to offer its class of probationers; then, having secured them, the training school should make good, and, having made good from time to time, there will be very little difficulty in securing other probationers. There are a good many young women, more than at any other time in our history, taking up nursing today; but there are so many hospitals, large and small, with training schools, that it seems as if we were really having a great scarcity. The hospitals are feeling the scarcity, not because the number of young women entering schools has decreased, but because the demand has increased. I believe that if the community in which the nurse works gives her a place in the community, and the hospital itself does its part toward the nurse, that will be good advertising, and will secure probationers for the school.

HOSPITAL CHARGES.

MISS ETHEL DOHERTY, Holyoke: I should like to ask what hospitals are doing generally in regard to the charge per week for one week's nursing. Some of the hospitals charge exactly one week; that is, if the patient goes in on Monday at 12 o'clock and goes out on the following Monday, that is one week. We have been in the habit of charging for eight days; having our day end at midnight, and charging a whole day for every day or part of a day; so that a patient coming in on Monday at noon, and going out Monday at noon would be charged for eight days. We are trying to revise that system.

MR. BRAY, Newton Hospital: We had that same problem to meet some little time ago. We charged both for the day the patient came in and the day he went out. Then, later, we made a charge of a double price for the first day; on a private room at the rate of \$5 a day, the charge was \$10 for the first day and \$5 for each succeeding day. In that way we accomplished the same thing as in charging for the first day and the last day full days. But we had trouble with that; the doctors found it difficult to explain why there was a double charge for the first day. And so, for the past two years, we have adopted the plan of charging for a single day, but making the first day cover from the hour of admission to six o'clock on the following day, and

all other days to begin at six o'clock; so that if a patient comes in before twelve o'clock at night, his first day would end at six o'clock; if he comes in after twelve, his first day would end at six o'clock the following day. That plan has given better satisfaction than any other we have tried.

MR. PORTER: The trouble is occasioned by making weekly rates. I don't believe anybody goes to a hospital to stay a week; they go to stay as short a time as they can. It is different from going to a boarding house: if you have a job, you want to hold it more than a week; if you are going to a hospital, you want to make the time as short as possible. In Malden we have no weekly rate; we found it was too much trouble explaining to people what a week was. It is more convenient to have daily rates, and make the charges on that basis.

DR. BROWN, Mary Fletcher Hospital, Burlington, Vermont: We charge for the day of admission and the day of discharge as one day, regardless of the length of time they stay.

MISS BOOKER, Corey Hill Hospital: We make no charge for the day the patient enters, but we do charge for the day of discharge, regardless of the hour.

DR. HOWLAND: The question-box is placed just outside the door, and I hope we shall have a great many questions.

After the papers of this afternoon, we plan to have questions placed in the box answered, and I hope the questions will be there.

Meeting adjourned at 12:30 p. m.

(To be continued.)

Original Articles.

OBSTETRIC EMERGENCIES.

By R. S. TITUS, M.D., BOSTON.

GENERAL acceptance by the medical profession and by the laity of the great value of careful medical attention of the pregnant patient has greatly reduced both infant and maternal mortality and morbidity. This acceptance has come largely through intelligent propaganda sent out by the Child Bureau, United States Department of Labor, the American Child Hygiene Association, and state medical societies. It has aroused the interest of everyone in the condition of the pregnant woman, her limitless economic and social value.

State legislatures and the national government have busied themselves about legislation, relieving the financial burden of child-bearing, and providing adequate medical care before and at confinement. Much of such legislation is opposed as too socialistic, as derogatory to the

medical profession, and in general as depriving individuals of their free choice; but in spite of whatever may be said for or against it, all such activity shows how the wind is blowing. It means that people are now thinking about something which ten to twenty years ago was not even thought of. It means that child-bearing is a recognized problem of national importance, a condition in the past which has shown results to be ashamed of, and more than anything else it means that there is a remedy worth applying.

Intelligent prenatal care begins with the beginning of pregnancy, and, carried forward until its termination, has achieved definite results. It has ruled out as unfit to bear children, the chronic nephritides, certain tuberculars, the severe cardiacs, profound diabetics, and saved such patients from an obstetric death and for a life not further impaired. It has designated as hospital patients, not to be left in their homes in isolated communities, those whose bony pelvis make Caesarean a necessity, thus reducing to a point almost negligible the brutal craniotomies of twenty years ago. It has reduced the incidence of early miscarriage by thoughtful hygienic advice, and careful reposition of retroposed uteri. By routine blood analysis, it has singled out the syphilitics, and has made intensive anti-syphilitic treatment possible, with a distinct lowering of infant mortality from the specific etiological standpoint. It has found out the healthy pregnant patient and has kept her healthy. It has recognized early toxemias with increased blood pressure and albumin, and has prevented the occurrence of actual eclampsia, by intensive treatment and premature delivery. In this latter type of case, the occurrence of actual eclampsia has been reduced almost to the point of non-existence. It alone is worthy of all the kind things said on every hand of prenatal care.

All this, prenatal care accomplishes directly, but there are conditions which can neither be foretold nor prevented, serious accidents which will occur, and which adequate prenatal care cannot foresee or avert, and which must be met directly and intelligently to carry on the wonderful work of prenatal care to its ultimate successful conclusion. These represent the *true emergencies of obstetrics*.

Obstetrics deals with the pregnant woman and the unborn baby. Obstetric emergencies are acute conditions which jeopardize the life of either or both the mother and child. Of course, indirectly, any serious complication affecting the mother also affects the baby, but there are conditions which primarily affect the baby, even when the mother is in perfectly normal condition.

The first large class of cases, which are true obstetric emergencies, are bleeding cases. A perfectly well woman at or near the end of pregnancy, with no warning at all, whose urine is normal, whose blood pressure has not risen, may be seized with a profound hemorrhage.

While an initial bleeding attack is rarely severe enough to threaten life, its successor may come at any moment, and the first sign of bleeding must be looked upon as a distinct warning of impending danger. It matters little how physically perfect anyone is, loss of blood cannot be looked upon with unconcern. Post-operative hemorrhages are often fatal. Loss of blood is serious. Its replacement in time means the saving of life. Blood transfusion is one of the most valuable advances in medicine. Experience has taught that many early failures were caused by the transfusion of blood not acceptable to the recipient. Before being safely done, the blood of the donor must be found to match that of the recipient. It is a very simple matter during pregnancy to match the blood of the pregnant patient with that of her husband, or members of their families, and with a known group No. 4 individual, to be absolutely sure of an acceptable donor. Then, if the need of transfusion arises, valuable time has been saved, which must be consumed in blood matching before the actual transfusion can take place. This blood matching during pregnancy should be a routine procedure, for one never knows which patient may bleed before or after delivery, or which patient will need transfusion because of profound shock. Knowing that one has at hand an acceptable donor, if the need should arise, gives one a feeling of great comfort. Trying to get an acceptable donor at the time transfusion is necessary, is worrisome.

Bleeding cases which arise late in pregnancy need an intelligent diagnosis before intelligent treatment can be instituted. A very little blood should be looked into, its cause ascertained and its diagnosis established. The amount is of little significance. The smallest stain may be a forerunner of a severe hemorrhage, and its cause the most serious,—the centrally implanted placenta praevia. On the other hand, a very large amount may be really insignificant, when its cause has been ascertained to be merely ruptured varicose veins. It should be a routine never to be disregarded to examine vaginally every patient who bleeds at all. A diagnosis can be made in no other way. Such an examination can be done rightly only in a hospital, where all aids for true emergencies are at hand. For example: Mrs. S., eight months pregnant, reports that she has flowed a little. She should be taken into a hospital, after it has been found that her condition allows immediate removal. An acceptable donor should be got. The examination should be conducted, of course, under strict asepsis. The entire kit for bagging should be boiled. A Caesarean kit should be ready for immediate use. The patient should be under gas or ether, if a satisfactory examination cannot be made without. In other words, all should be in readiness to meet the condition that examination proves exists. Such routine will prove unnecessary very often, but the one time will come when

this habit will justify itself. The causes of bleeding in the latter months of pregnancy are:

- Ruptured Varicose Veins.
- Low Attached Separated Placentas.
- Completely Separated Placentas, Normally Attached.—Placenta Ablatio.
- Placenta Praevia:
 - (a) Centrally Implanted Complete Placenta Praevia.
 - (b) Complete Placenta Praevia, not Centrally Implanted.
 - (c) Partial and Marginal Placenta Praevia.
 - (d) Beginning Labor.

Varicose Veins: These may be on the labia or anywhere inside on the mucous membrane of the vagina. The amount of bleeding from these may be very great, but seldom serious. Diagnosis is made by inspection, or by feeling the clotted surface when the bleeding has ceased. Rarely is anything more than counterpressure necessary; occasionally ligation. Of course there is no danger to the foetus. There is no need of meddling with the uterus. Labor need not be started.

Low Attached, Partially Separated Placentas: These cases often bleed before labor starts. When seen the uterus is soft, the foetal heart distinct, there is no sign of internal bleeding. Vaginally the presenting part is felt all around the lower segment of the uterus above the cervix, and the finger, if put through the cervix, feels no placenta. Inspection reveals no varicose veins. Hence, by elimination, bleeding must come from a small area of placental separation, and this clinically is proved to be associated most frequently with the low attached placenta. Such cases should be kept quiet in bed for a few days, and if no further bleeding occurs, allowed to be up and about until labor comes. Very rarely such cases may bleed rather freely, too freely for the safety of the mother, and if she be not in labor and a primipara, abdominal delivery is probably the most conservative; but such instances are very rare. In such conditions in multiparae, where dilatation may be accomplished probably in a short time by the use of the bag, the bag alone would be sufficient. Often during labor there is some more bleeding, but usually, however, it is not enough to interfere with placental and uterine interchange, or enough to jeopardize the mother. After delivery the diagnosis is confirmed by finding the membranes torn near the placental edge, where there may be an adherent old blood-clot.

Completely Separated, Normally Situated Placentas, the Placenta Ablatio: The clinical picture of this type of case is very distinct. External bleeding is usually small in amount, the uterus is drumlike in feel, the foetal heart is gone,—because the placenta has separated,—the maternal pulse is up anywhere from 100 to 130, depending upon the amount of bleeding that has occurred. The blood pressure may be low, and in extreme cases, of course, very low. Vaginal examination reveals no placenta praevia. This

bleeding will continue until the uterine sinuses can contract. This cannot be accomplished until the uterus is emptied. A few of these cases are in such poor shape when seen that transfusion should be done as soon as, or before, any attempt is made to empty the uterus. The method of emptying the uterus depends upon whether or not the patient be in labor. If the patient be not in labor, primipara or multipara, the only conservative method is abdominal Caesarean section; if the patient be well in labor so that delivery from below may be done with no shock, version after dilatation is the method of choice. The bag is contraindicated, it may hasten dilatation, but in the meantime it in no way controls bleeding—accouchement forcé barbaric. Vaginal Caesarean is applicable to only those cases up to eight months, when the cervix may be brought down to a point where its sewing may be accomplished. A good number of placenta ablatio cases are seen associated with some degree of toxemia, but more specific etiology is unknown.

Placenta Praevia: The various degrees of placenta praevia are so named because of the amount of the internal os that is overlapped by the placenta. The centrally implanted complete placenta praevia is, of course, the most serious and, fortunately, very rare. It may give rise to bleeding any time after six and a half months, but often shows no sign until near term. The initial bleeding may be very slight. To go on the assumption that the cause in the particular case is of no real importance, and merely to put the patient in bed for a few days, making no attempt to diagnose the condition, is nothing short of criminal. One example will prove this.

A multipara had bled three different times in the last month of pregnancy; the attending physician had put the patient to bed each time, and had done nothing to determine the cause. The fourth attack occurred with labor and the hemorrhage was excessive. When seen she was almost pulseless, with a blood pressure of only 80, and died shortly after delivery. Had this patient been examined, and the cause of the bleeding determined at the time of the initial hemorrhage, and proper means of delivery had been instituted, there is no reason at all why she should not have lived.

Vaginal examination in these cases, if the patient be not in labor, will reveal something in the lower segment, anterior and posterior, above the cervix and between the presenting part and the finger. If the finger is put through the cervix, one feels the sponginess of the placenta and elicits more bleeding. If the patient be in labor and there be sufficient dilatation, the diagnosis is made by feeling the sponginess of the placenta inside the cervix. If the patient be not in labor and actually bleeding, immediate delivery is best. In primiparae, abdominal Caesarean section is without question the conservative operation. In multiparae not in labor, Caesarean is

safest, but the rubber bag may be used. Here, the bag, put through the placenta or outside the placenta, controls bleeding by pressing onto the uterine sinuses and hastens dilatation. Delivery, when the dilatation is accomplished, is by version. The foetal mortality of these cases delivered from below is extremely high. The Braxton-Hicks maneuver of going right through the placenta, when the cervix is not fully dilated, and grasping one leg, whereby to pull the buttocks on to the placenta, controls further bleeding, but frequently sacrifices the baby. If there be no bleeding when the diagnosis is made, and there is reason to wish to wait for the sake of prolonging pregnancy for the sake of the baby, the patient should be kept in a hospital to have Caesarean, when the bleeding recurs, or when the pregnancy has advanced to a stage where the baby has a good chance. If the patient be in labor, or well advanced in labor when seen, it is far better to use the bag to accomplish full dilatation than to manually stretch up the cervix. When the bag comes out with full dilatation, the hand is thrust through the placenta, and the baby delivered by version. It is well to bear in mind that placenta praevias of all types have a tendency to bleed after delivery. It is customary with some men to pack all placenta praevia uteri after delivery, but such a routine is not necessary. Remember the possibility! Be ready to meet the emergency when it arises, but do not forget that putting gauze into the uterus is a possible cause of sepsis.

Complete placenta praevias, not centrally implanted, but where the edge of the placenta falls way over the internal os, are diagnosed only by vaginal examination. It is oftentimes very difficult to differentiate between the centrally implanted placenta praevia and those which are complete because the internal os is overlapped. If the patient be in labor, with any dilatation at all, the differentiation can be made. If these complete praevias are diagnosed when not in labor, the safest and most conservative procedure, if immediate delivery seems best, is abdominal Caesarean section. The rubber bag is more applicable to the multiparous cervix than it is to the primiparous. If these cases are in labor when seen the bag is really all that is necessary, and the bag should be used until absolute complete dilatation has been obtained. It is far safer with three-finger dilatation in the multipara, to use the bag to accomplish complete dilatation than it is to dilate manually this soft placenta praevia cervix. Without question these cases do not stand dilatation well, even the moderate amount of dilatation that is necessary in multiparae showing three-fingers dilatation to begin with. They stand no shock at all, and one should be ready to transfuse any case of this sort after delivery. If the bag is used, it may be put outside or inside the ovum and has the twofold purpose of controlling bleeding and hastening dilatation. After the delivery of the bag, ver-

sion is the operation of choice. Braxton-Hicks maneuver is advocated in those cases showing some dilatation, but the bag gives far better results.

Partial and marginal praevias are diagnosed, of course, by vaginal examination. The partial ones are best treated universally by the bag, with version after the bag has been expelled. The marginal praevia can oftentimes not be felt until dilatation is pretty nearly complete. Simpler than the bag, and a procedure which works just as well, is rupturing the membranes. This allows the presenting part to fall down upon the edge of the placenta and controls bleeding during labor. It should be remembered in this type of case that directly after the head has come through the cervix, so that the neck is lying opposite the marginal praevia, there is no pressure exerted at that instant, so that consequently more bleeding might result. For this reason deliver immediately, with forceps, as soon as the head does come through the cervix. Any of these cases may bleed enough to require transfusion and, if at all necessary, do not hesitate.

Beginning Labor: Only a word as to the bleeding associated with the beginning of labor. This is merely the show, and if it be enough to excite suspicion, vaginal examination revealing nothing, will suggest the only possible cause.

Consider now post-partum hemorrhage. Its causes are:

- Atony of the uterus.
- Retained placentas.
- Partially adherent placentas.
- Lacerations.
- Ruptured varicose veins.
- Unintelligent handling of the third stage.
- Inversion of the uterus.

An *atonic uterus* is one which has lost its tone. Bleeding occurs after the birth of the placenta. The normal contraction and relaxation curve is transposed, so that the uterus is soft and flabby a much longer time than it stays in contraction, or it may stay relaxed all the time and contract none at all. It is a very safe routine to follow the uterus, as the baby is delivered, and hold on to it carefully after the baby is born. If the uterus is not held, the placenta may separate, may not be extruded through the internal os, and may lie in the internal os, acting as a ball valve, behind which a great deal of bleeding may go on. The uterus which is tardy in its contractions bleeds slowly, and a great deal of blood is gradually lost. All uteri should be held for an hour and not left then unless they are in a state of constant, firm contraction. Atony of the uterus is most often seen in (1) hydramnios and twin cases, where the muscle has been unnaturally stretched; (2) long, tedious labors, where its power has been all used up in attempting to rid itself of the baby; (3) precipitate labors where normal retraction has not had sufficient time to occur following contraction. Conducting any one of the

above classes, be particularly watchful of the uterus. A post-partum hemorrhage from an atonic uterus is a very unhappy and fearful sight; the blood may just gush out; the uterine sinuses at the placental site are wide open and will remain so until the muscle contracts to shut them down. It is now customary with many men to give an ampule of pituitrin, subcutaneously, as soon as the baby is delivered. This has no harmful effect and may hasten the placental separation. An intramuscular injection of ergot ought always to follow the placental delivery, where pituitrin has been used.

The treatment of an atonic uterus is to give the muscle some tone. Pituitrin and ergot both are great aids; manual massage and the external application of ice help; hot intrauterine douches are of value. Packing is the last expedient, because of the danger of introducing infection, but it should be done even at the expense of sepsis, when all else fails, because a septic patient is better than one who bleeds to death. If packing has been resorted to, the fundus should still be held. Fatal hemorrhages have occurred behind packs because of uterine relaxation. The after-treatment is the replacement of lost blood—transfusion. If it seems not quite necessary to transfuse, rectal water, intravenous salt or subcutaneous salt will very rapidly replace fluid. Morphine is the drug *par excellence*. Strychnine does more harm than good. Raise the foot of the bed, keep the patient warm with heaters and blankets, and subsequently give her all the food, sunlight and fresh air that is possible. Intrauterine packs should be removed in not later than twelve hours; it is unnecessary to give an intrauterine douche after the removal of the pack.

Post-partum hemorrhage due to *retained placenta*: In such cases, the placenta is known to have separated, the fundus is higher than it should be, the cord has descended, the Credé maneuver has been unsuccessful; the placenta must be removed. It usually is caught at the internal os, and can be removed with no great difficulty or danger. Packing may be necessary as a last resort, when the placenta is got, but usually not. Always etherize the patient. In the manual removal of the placenta very careful asepsis must be observed. Clean gown, clean gloves should be put on. The patient should be under ether, for the removal is painful and any struggling on the part of the patient may do immeasurable harm. The hand not entering the uterus should grasp the fundus from above, thus giving counter resistance to the hand in the uterus. In this connection the succenturiate placenta should be considered. This is diagnosed by seeing on the delivered placenta severed veins, running over cut membranes. If there be bleeding, the succenturiate must be got, and must be manually removed. Such a removal is very dangerous. The vagina cannot be sterilized, and the gloved hand goes through the

vagina and intimately attempts to disengage the placental tissue. Infection often follows. The uterus from which such placental tissue has been removed may need subsequent packing.

The slightly *adherent detached placenta*: This is usually very serious. The detached area has exposed a very big bleeding uterine area, the flowing leads to the belief that the placenta has separated and further time is wasted in attempts to Credé; all the while more bleeding results. Ultimately, the patient has lost much more blood than was realized, and is in poor condition when manual removal of the placenta is attempted. Such patients can lose no more blood. If there is any bleeding at all after the removal of the placenta, pack the uterus without hesitation. Transfusion here is imperative and a life-saver.

Lacerations: The great majority of lacerations caused by childbirth do not cause hemorrhage. Perineal lacerations are repaired at the time for the purpose of bringing together separated tissue, rarely to control bleeding. Bleeding caused by lacerations appears as soon as the baby is born. Cervical lacerations, bad enough to cause post-partum hemorrhage, are seen infrequently nowadays, because accouchement forcé is done so rarely. It is possible for a cervix to be torn badly enough at normal labor to require suturing for the purpose of stopping hemorrhages, but this is very, very rare, and it is also unusual for the cervix to be torn badly in operative delivery where the cervical dilatation has been complete, or nearly so, before operation. Cervical tears are diagnosed by bringing the cervix into view and are treated by suture. Veins near the clitoris, when cut by forceps which extend too far anteriorly, bleed very freely. When recognized and tied, the bleeding is seldom serious and stops immediately. Varicose veins may rupture spontaneously with the birth of the baby. The big grape-like masses so often seen on the labia bleed very profusely, but not really seriously, for counter-pressure or a suture will stop them very quickly. Perineal lacerations rarely involve a small artery or big veins, but the bleeding from these is very quickly stopped in sewing.

Post-partum hemorrhage is also caused by the *unintelligent handling of the third stage*. Too hasty attempts at Credé may cause premature separation of the placenta, with resulting relaxation. There is only one time to Credé a fundus and that is when the placenta has separated. Dogmatically waiting for a given number of contractions sometimes results in leaving the placenta in the uterus after it has separated; other times it results in attempting to express the placenta before it has separated. Placental separation evidences itself in two ways: the descent of the cord, and bleeding. There can be no bleeding unless there be some lacerations, until the placenta separates somewhat or entirely. Too vigorous attempts at Credé result occasionally in inverting the uterus, with or without separa-

tion of the placenta. Inversion may occur spontaneously, but probably infrequently; usually from poor management.

An *inverted uterus* causes post-partum hemorrhage. If the fundus, inside out, appears at the vulva, the diagnosis is simple. If the fundus is not in sight, attempts to look at the cervix to ascertain the cause of bleeding reveal the true condition. The inverted uterus must be replaced. Manual attempts, under ether, may be successful; if not, laparotomy is necessary. Patients in whom the uterus has inverted are usually in profound shock, and transfusion is often necessary.

Before leaving the subject of post-partum bleeding, a closely allied condition should be considered,—the completely adherent placenta. In one sense it is not an emergency, for it causes no bleeding. This condition is one of the most serious complications met with. Fortunately, it is rare. Its seriousness results from sepsis, post-partum bleeding and rupture of the uterus as possible sequelae of its removal. The truly adherent placenta shows no bleeding. After waiting a reasonable time, an hour for example, after the baby comes, during which time there have been contractions but no descent of the cord, or bleeding, the diagnosis of completely adherent placenta is made. It is the usual custom, once the diagnosis is made, to remove the placenta manually. The placental site, where the uterine sinuses are open, is the point where infection most easily occurs. The vagina cannot be sterilized. If nature has not completely attenuated the organisms normally present in the vagina at labor, of course they are carried up into the uterus by the gloved hand. Attempts at separation of the placenta are traumatic, no matter how gently performed, and of course organisms thus introduced are deposited where they will do most harm. Adherent placentas manually removed go septic in at least one-third of the cases and the mortality from the complication is really appalling. As already mentioned, attendant dangers besides sepsis are rupture of the uterus and post-partum hemorrhage, and because of these dangers the manual removal of the placenta is looked upon with much hesitation. Other methods of treatment have been advocated. One man advises, after waiting twelve hours with no evidence of separation, to cut the cord at the introitus and remove the placenta by extraperitoneal hysterotomy. This seems unnecessarily radical. Another suggestion is to leave the placenta in the uterus indefinitely, and do nothing unless bleeding occurs. Theoretically, so long as the placenta remains adherent, and does not get infected (and it must be admitted that going into the uterus through the vagina is the surest way of causing infection) it can do no harm. This conservative inactive method is not generally adopted, but is deserving much consideration. If the placenta is removed manually, small fragments are left behind

which may cause bleeding. If there is any tendency to bleed after removal of the placenta, the uterus should be packed, and if one knows that the uterus has been ruptured, one should consider seriously the need of going into the abdomen. So much for the bleeding cases.

Actual eclampsia as an obstetrical emergency is met with very infrequently where prenatal care has been adequately given. Nevertheless there is an occasional fulminating eclamptic, which comes up even in the best regulated obstetrical practices. The disease, so gradual in its onset, with its slowly rising blood pressure, the increasing urinary abnormalities, once in a while pops up almost overnight. The patient has had no oedema, her urine has been normal, her blood pressure has not risen, and right out of a clear sky a seizure presents. The treatment of such cases is now under advisement. There are two schools: The first says to leave the patient alone, get her kidneys working, give her morphia, do not operate more energetically than to start up labor; the other school bases its opinion upon the hypothesis that the cause of eclampsia is intimately associated with the uterine contents, and that unless an attempt is made to remove these, more absorption will take place, and advises immediate delivery. In one respect, so far as treatment goes, everybody is in accord. No one today advises accouchement forcé. This method of rapidly emptying the uterus was pretty universally in vogue ten or fifteen years ago. Patients not in labor were put on the table with a pulse of 80, the cervix was manually or instrumentally dilated, the baby delivered, the whole process consuming perhaps twenty minutes; the result very frequently was maternal death, and death due to division of the cervix and shock, rather than to eclampsia. Because of this general experience, rapid delivery is no longer entertained. It still seems best, however, to most men, to empty such cases immediately, and this had best be done by abdominal or vaginal Caesarean section, depending upon the duration of pregnancy and the character of the cervix. If seizures occur unannounced in the midst of labor, allow labor to proceed, using oxygen for convulsions, and deliver operatively, when cervical dilatation is complete. Post-partum eclampsia is treated by blood-letting, oxygen for the convulsions, morphia, forcing fluids and catharsis. The after-treatment of any eclamptic is blood-letting, when the blood-pressure remains above 150, and forcing fluids to the limit, getting fluids in by rectum, under the breast, or into the vein. Morphia should be used to the physiological limit. Excessive catharsis is not rational. Repeated large doses of salts surely dehydrate the blood; moderate catharsis is more rational.

Before leaving that part of obstetric emergencies which deals primarily with the mother, consider the rather infrequent complication, obstetrical shock. Obstetrical shock is just like surgical shock. It is characterized by low blood pres-

sure, pallor, thready, rapid pulse, clammy perspiration, and, in general, exhibits a patient in a most extreme condition. This is seen after normal labors as well as after labors prolonged or complicated, after easy non-operative as well as after difficult operative labors. Of course, one is not surprised to see it associated with post-partum hemorrhage, but it is a very distressing and wearisome experience to be summoned a few minutes after attending a perfectly normal, healthy girl through an easy labor, to find her in a state of extreme collapse. One unconsciously feels for the fundus, and finding it hard and firm, with no unusual bleeding, all fear of hemorrhage ceases and one realizes that he has to deal with shock. Such cases when given morphia, heaters, and blankets, with the foot of the bed raised, will come around in a short time, but nevertheless they are very disconcerting. More unpleasant are the shock cases associated with operative delivery (which at the time seemed easy enough, but which, in retrospect, with the patient in a state of collapse, are crowded with alarming possibilities) or with hemorrhage, moderate or severe, which had seemed checked. In addition to the treatment suggested for the previous type, when the element of bleeding has entered, transfusion should be done without delay. The operation can be done immediately, for forethought has summoned on the spot an acceptable donor and transfusion shows the same remarkable effect for these shock cases as for the more or less exsanguinated cases that it has been suggested for previously.

So far the mother has attracted our attention. The emergencies enumerated affect her welfare. The second problem of the obstetrician is the baby, and I say second, advisedly, for the baby should never have preference over the mother, nor should any operative procedure be attempted for the baby, which carries with it any added risk to the mother. The mother comes first, always; not that the baby is not given due consideration! Whenever circumstances arise in labor which militate against the baby, all efforts to save the baby should be entertained, remembering that they should be entertained and executed at no added risk to the mother. Where prenatal care has not been intelligent, mothers with small pelvis in relation to the baby, are often allowed to go into labor for hours, when Caesarean was the only course to pursue, to safeguard both. But when labor has progressed unduly long, where infection in the mother may exist, classical Caesarean, while insuring a living baby, is out of the question; maternal risk is too great. Such cases are wilful or ignorant emergencies and are to be treated in one of two ways,—either sacrifice the baby by craniotomy or follow Caesarean by hysterectomy. Pelvic tumors unrecognized before labor, obstructing vaginal delivery, are also ignorant emergencies and hold no real place in a paper which presupposes prenatal care. There are, however,

legitimate foetal emergencies which occur in anyone's practice which need rules of guidance. The condition of the baby during labor is followed by watching the foetal heart rate. We recognize as normal the variations of the foetal heart rate during and after contractions. These are not worrisome, but a distinct drop or rise in foetal rate, maintained and not spasmodic, means something. Such changes are evidences of foetal embarrassment. The cord may be pinched, the labor may be telling on the baby and the baby may be getting tired. If, along with the foetal heart change, there is a discharge of fresh meconium, we know that the baby is embarrassed right now. This embarrassment may be only temporary. Whatever the cause it may right itself in a few moments, and may, on the other hand, be an indication that the baby is truly in bad shape and in dire need of assistance, if it is to be born alive. What is to be done? Upon what shall the decision rest? The answer is simple. Do nothing for the baby at added undue risk to the mother. If labor has progressed so that delivery can be terminated right away, labor should be terminated. Simple forceps through the dilated cervix carries little or no risk and the child has a definite right to this risk, and the patient would want to assume that risk if she were asked. Now, on the other hand, suppose the above mentioned indication of foetal embarrassment presented itself early in labor, is operative interference justified? No operation emptying the uterus immediately can safely be done on the mother when the cervix is not dilated except Caesarean section. If the infant is really embarrassed, a dead infant may be the reward for a major procedure. If, on the other hand, the infant's difficulty is to right itself (and how can this be told?) an unnecessary operation requiring repeated Caesareans at subsequent deliveries will have been done. In such cases the only conservative procedure is to leave things alone. Caesarean is not to be sneezed at. Its mortality is higher than any such ratio of chance warrants, and should be condemned for the above indication.

Prolapse of the Cord: Prolapse of the cord is the only other real emergency occurring during labor, which affects the baby. This cannot occur when the presenting part fits snugly into the pelvis. But if the baby be little in comparison to the pelvis, and the cord long, there is plenty of room for the cord to slide down alongside the presenting part. If there be no presenting part in the pelvis, as in transverse presentations, when the membranes rupture, the cord of course prolapses. The importance of prolapse of the cord is the possibility of pressure on the cord, resulting in foetal asphyxia. Whenever this occurs, when delivery can be done without added undue risk to the mother, delivery from below should be accomplished. If the occiput presents and is low, do forceps; if the occiput is not low, do version. If the cord has been down some time when the patient is first seen, and has ceased to

pulsate, conduct the case without thought of the baby, for the baby is dead. Allow nature to terminate the delivery normally, unless there be a malposition which requires operative interference for its own sake. Very rarely, early in labor, before cervical dilatation has progressed to a stage of safe vaginal delivery, the cord may prolapse. In such a case replace the cord and either use the bag to hasten dilatation or do nothing. Caesarean section for this complication is entirely unwarranted.

CONCLUSIONS.

Prenatal care has accomplished very definite results. It has ruled out patients unfit to bear babies; it strives to keep well those physically fit; it does away with craniotomies by substituting Caesarean at a safe time; it recognizes pelvic tumors obstructing labor; it almost entirely does away with actual eclampsia. Obstetrical emergencies which cannot be foretold or revealed will arise, which need intelligent diagnosis and very intelligent treatment. Obstetrical emergencies are conditions arising which have to do with the mother and the baby. As to the mother, the most important cases are those which bleed before, during, and after labor; these also include the adherent placenta, the inverted uterus and shock. As for the baby, foetal embarrassment due to pinched cord or prolapsed cord should be dealt with only after remembering that the mother should be subjected to no added risk for the sake of the baby.

A CONTRIBUTION TO THE THEORY OF THE LOCALIZATION OF MENTAL FUNCTIONS.*

IV. Conclusions

It will be simpler, perhaps, in attempting to make a contribution to theory, to begin with the known, to begin with facts. These facts can also be grouped as anatomical, physiological and psychological facts.

The anatomical facts, which, as you understand, are the common knowledge of all medical men, will have to be considered for the purpose of this contribution, from a rather special standpoint. I have chosen to call the anatomical elements to be considered "units." Thus, for my purpose, each muscle is a unit, each gland is a unit, each system of fibres in the spinal cord is a unit, each segment of the autonomic system is a unit, though we are all aware that each of these so-called "units" is composed of much simpler histological elements, chemical elements, functional elements or even pathological elements, if they are diseased.

So much for the anatomical side. I might have added articular surfaces to my list of units. I might have added skin, eye, ear, tongue, nose, but I have not attempted a complete list. If we add these, our list is almost complete for my purpose.

Turning to the physiological side, another aspect presents itself. That is, the fact of "functional units." For example, we know that muscle never functions alone except under experimental conditions. It functions in conjunction with its motor nerve and, moreover, it sends centripetal impulses back to the central nervous system—a fact which is not often considered in physiological matters. This combination of motor nerve, muscle and sensory or centripetal nerve, I would regard as a functional unit.

In the same way, for the purposes of this article, we must consider neuro-glandular combinations as unitary in a physiological sense. In the same way, and for the same purpose, we may regard the genito-urinary system as one, though composed of nerve, muscle and gland; the gastro-intestinal system, though composed of nerve, muscle and gland, and the cardio-respiratory system, though composed of nerve and muscle almost exclusively. Perhaps these latter, the cardio-respiratory, gastro-intestinal and genito-urinary, are better called physiological systems than physiological units. However that may be, the point that I want to bring home is that for the purpose of this paper, they must be considered together, whether you call them units or

systems. To these we might add the glands of internal secretion, perhaps, calling each with its appropriate nerves a unit and the entire set of opponents a system. However you do it, the main point, I think, must be clear.

There is another peculiarity in the physiology of these units or systems which is of a very general biological nature. By that, I mean, that this peculiarity does not end with either systems or units, but seems to apply to the simpler histological elements, and even to chemical and physical phenomena. That is the matter of force and direction, or order. Physical phenomena, chemical phenomena, the functions of the cell, of the unit or of the system, take place with a certain force and in a certain direction, or—to put the last in other words—with a certain orderliness. This observation seems to be of a fundamental sort, for this phenomenon appears to be due to the nature of matter and force. At least, so far, we have no other scientific explanation of it. This form of force, I prefer to call kinetic, thus linking it up somehow with that form of energy known as kinetic, and at the same time distinguishing it from static, which it is not, and from dynamic, which means both static and kinetic, and which is, for that reason, too comprehensive a term.

As for localization, anatomically and physiologically, we know, fairly well, certain of the cortical areas which have to do with the movement of striated muscle. We know those which have to do with certain of the senses, namely, the special senses, and to some extent skin sensibility. But there are large areas of the cortex which have not been mapped out as to function.

Of the subcortical ganglia we know indirectly and by direct experiment that certain parts are concerned with the bladder and genital region, that other parts control the motor expression of the emotions, and so on. Some of this knowledge is very definite and well rounded, more of it is still in that hazy stage preceding absolute certainty.

Turning finally to the psychological side, we have as elements or units sensation, association, reaction and inhibition. All other psychological processes are systems reducible to these units. Thus perceptions of all kinds can be reduced to these four units whether they are simple perceptions of concrete objects in the environment or whether they are complex perceptions such as those of space, time and meaning. All ideas, whether memory, imaginative, or general, can be reduced to these. All activities, whether those of will, of attention, or of thinking, are made up of them. All of our inner states, such as feelings, whether simple or complex, emotions, and attitudes, consist of them. Finally it may be said that the personality, consisting of an interplay of perceptions, ideas, activities, and inner states, is merely an expression of the manifold ways in which the organism senses, associates, reacts, and inhibits. Even such

things as self-consciousness, unity of personality, variations in personality, the feeling that the self takes an incomparable rôle, the consciousness of identity in successive periods of time, or the fact that the mind is thought of as representing the real personality and that the body seems to belong to the outside world, all fail to escape the thralldom of sensation, association, reaction, and inhibition.

The personality is the product of the interrelations and interactions of all these psychological systems and each system reduces to the four elements or units, which I have named, now so often.

From this ground material, the writer has attempted to raise a superstructure the postulates of which now follow. Beginning again with the anatomical side, we may postulate that the so-called association pathways in the brain do not connect one sensory centre with another directly, as has been supposed by the anatomists till now. These pathways rather connect the sensory centres for the muscle sense with those for the other senses and probably also connect the cortex with the basal ganglia, the fibres forming these latter pathways most probably running some in the one direction and some in the other, so far as we can judge on present information.

This postulate is made because of the nature of association, speaking psychologically. Moreover, we know of no instance where an ether wave may produce a sensation of sound, or where an air wave may produce a sensation of light. I might take up all the sensations in the same way but these examples above ought to carry my meaning to you.

If what I have said be true, we may add this system of fibres to our others. We have postulated a fibre system, known to exist, it is true, but not thought of in just this way, I imagine.

The function of this set of fibres then is sensory-sensory (perhaps associational in this way), that is to say, it links muscle sense with the other senses. We have then another functional unit, a postulated functional unit, the sensory-sensory neurone or the sensory-sensory system of fibres.

Referring again to the matter of energy or force, which we have been pleased to call kinesis, we may postulate that this force varies both in energy and in direction or orderliness. The variations in force we may assemble into those which are greater than usual and those which are less than usual. The former may be called hyperkinesis and the latter hypokinesis. The variations in direction or orderliness of this force we may call ataxia.

A study of these terms and of the conceptions embodied in them has led me to conclude that they are broad enough to include all variations both in the reaction of the normal and the pathological. They represent general ideas of a very broad and inclusive sort and yet specific enough in their generality to permit application

to every known case both in normal physiology and in pathology.

The last of my postulates in the physiological field is that the unmapped areas of the brain, the so-called silent areas, are probably sensory in nature and take in the gustatory, warm, cold, pain and touch senses which so far have not been thoroughly mapped out for the entire body; next that the physiological systems or units known so well and for so long, do probably take part in every mental process by virtue of the fact that they constitute the anatomical and physiological agents of reaction and inhibition, and, finally, that this interplay of nerve cells, peripheral and central, cerebro-spinal and autonomic, together with their muscular and glandular end organs, is all there is to what we call mind. To explain further: When one says "perception" he merely expresses in a word the functioning of certain neuro-muscular, neuro-glandular and nervous units or systems. When he says "idea" he expresses another phase of function in the same apparatuses. And the same is true when he says "activity" or "inner state."

And when he says that a perception was normal or when he sees from his examination of a patient that the patient perceives normally, he understands in that observation that the neuro-muscular, neuro-glandular and nervous mechanisms subserving the given perception are normally functioning. The same facts are evidence in the case of ideas, activities or inner states. And if the personality is normal, such normality testifies, by itself alone, to the normality of these systems which I have named.

We have one more field in which to make our postulates before turning to the induction. In the field of psychopathology we may postulate, first, that all the symptoms that patients show may be grouped on psychological grounds. Thus our patients show disorders of personality which are due to disorders of self-consciousness, to changes in the feeling that the self takes an incomparable rôle, to change in the consciousness of identity or to change in that distinction between the mind and the body or to changes in those inner states, activities, ideas and perceptions which we have enumerated earlier.

Our knowledge of the structure of attitudes, emotions and feelings takes them back to reactions and inhibitions directly and through ideas to the sensations. Our knowledge of the structure of thought, attention and will shows the same. Our knowledge of the structure of ideas takes us through perceptions and our knowledge of the structure of perceptions takes us directly back to the four psychological elements. The anatomical elements or units we know fairly well. The physiological units we know also fairly well. Our postulates make it proper for us to group our psychopathology into hyperkineses, hypokineses and ataxias.

The inductions follow. In the first place, we may conclude that perceptions and ideas, if normal, mean that the cerebral cortex is normal. In the next place, we may conclude that if the activities and inner states are normal, the basal ganglia, autonomic and muscle and gland systems are normal.

If perceptions and ideas are abnormal, we may conclude that there is trouble somewhere, but we cannot say on that fact alone where the trouble is, especially if the trouble is a hyperkinetic or ataxic one. If it is hypokinetic or an extreme case that might be called akinetic, we may feel sure that the trouble is cortical.

If the abnormality is in the activities or inner states, we may follow the same reasoning. If it is an hypokinesis or akinesis the trouble is at least extra-cortical; if ataxic or hyperkinetic, it may be anywhere.

In practical cases the presence of an hyperkinetic symptom here and of an hypokinetic or akinetic one there serves to fix the trouble fairly well as to whether it is extra-cortical or whether it is cortical. If this can be done in every case of psychopathy, the practical meaning of this induction is of course tremendous.

The final end of this study should be to establish psychiatric diagnosis upon an anatomical and upon a physiological ground. Then we can add our etiological factor in each case, give our prognosis and prescribe our treatment in a thoroughly logical and scientific manner. Psychiatry will then become a part of general medicine. Psychology has made the first step. It is now distinctly the business of physiology to tell us more within its field and to chemistry and pharmacology to give us a rational therapeutics.

NOTE 1: Two elements I have omitted in this discussion. One is the effect of innate tendencies, the other the effect of training or habit. These may also affect physiological systems, making them over-function or under-function or function in an ataxic manner. Of course, in such cases we need reeducation and not chemotherapy. For prevention of such cases we need all the means being developed by the mental hygiene movement and not so much the prevention of physical disease. The prevention of the kinds produced by physical means will be aided by the prevention of syphilis, alcoholism, tuberculosis and by every well-organized public health measure which we have.

NOTE 2: According to the plan outlined here every diagnosis in psychiatry can be arranged as follows:

Physiology	Anatomy	Etiology
Hyperkinesis	Cortical Subcortical, etc.	Alcohol, Syphilis, etc.
Hypokinesis	Cortical, Subcortical, etc.	Alcohol, Syphilis, etc.
Ataxia	Cortical, Subcortical, etc.	Alcohol, Syphilis, etc.

Prognosis	Treatment
Usual expressions	Consider all factors
Usual expressions	Consider all factors
Usual expressions	Consider all factors

It may be that this formula is general enough to include all forms of disease. That, I have neither time nor inclination to pursue into its details at present.

The Massachusetts Medical Society.

PROCEEDINGS OF THE COUNCIL.

STATED MEETING, OCTOBER 4, 1922.

A STATED meeting of the Council was held in the Boston Medical Library, at 12 o'clock noon, October 4, 1922. The President, Dr. John W. Bartol, was in the chair and the following 106 Councilors present:

BARNSTABLE, W. D. Kinney.	MIDDLESEX SOUTH, E. W. Barron, E. H. Bigelow, F. G. Curtis, C. B. Fuller, F. J. Goodridge, C. E. Hills, L. H. Jack, F. R. Jonett, S. F. McKeen, C. E. Morgan, J. W. Sever, F. G. Smith, E. H. Stevens, A. K. Stone, Fresenius Van Nijys, H. R. Webb, G. W. W. Whiting, W. S. Whittemore, Alfred Worcester.
BERKSHIRE, A. P. Merrill.	
BRISTOL NORTH, Sumner Coolidge, F. A. Hubbard.	
BRISTOL SOUTH, E. F. Cody.	
ESSEX NORTH, R. V. Baketel, J. J. Bartley, J. Forrest Burnham, W. W. Ferrin, T. R. Healy, A. M. Hubbell, G. E. Kuth, F. D. McAllister.	NORFOLK, E. H. Baxter, D. N. Blakely, E. H. Brigham, A. N. Broughton, W. L. Burrage, W. A. Griffin, F. C. Jilson, G. W. Kean, Bradford Kent, Hale Powers, Victor Safford, G. H. Scott, W. J. Walton, Augusta G. Williams.
ESSEX SOUTH, F. W. Baldwin, J. F. Donaldson, H. K. Foster, W. T. Hopkins, J. F. Jordan, W. G. Philpen, A. N. Sargent, J. W. Trask.	NORFOLK SOUTH, C. S. Adams, O. H. Howe, G. M. Sheahan.
FRANKLIN, B. P. Croft, G. P. Twitchell.	PLYMOUTH, A. L. Beals, W. C. Keith, Gilman Osgood, F. G. Wheatley.
HAMPDEN, E. P. Bagg, Jr., A. C. Eastman, G. H. Jones, J. P. Schneider.	
MIDDLESEX EAST, L. M. Crosby, C. E. Ordway.	
MIDDLESEX NORTH, W. B. Jackson, J. A. Mchan.	

SUFFOLK.

J. W. Bartol.
Robert Bonney.
E. G. Brackett.
M. E. Champion.
Loretta J. Cummins.
Lincoln Davis.
G. B. Fenwick.
G. S. Hill.
W. C. Howe.
J. C. Hubbard.
H. T. Hutchins.
Donald Macomber.
G. B. Magrath.
R. H. Miller.
E. H. Place.
W. H. Robey.
Stephen Rushmore.
C. L. Scudder.
J. S. Stone.

SUFFOLK (continued).

Louisa P. Tingley.
F. H. Williams.

WORCESTER.

F. H. Baker.
W. P. Bowers.
L. R. Bragg.
G. A. Dix.
G. E. Emery.
Homer Gaze.
J. J. Goodwin.
R. W. Greene.
E. L. Hunt.
A. G. Hurd.
A. W. Marsh.
C. B. Stevens.
F. H. Washburn.

WORCESTER NORTH.

A. H. Quessy.

The record of the last meeting was read in abstract by the Secretary and approved by vote.

The President referred feelingly to the sudden death of Dr. William Andrew Dolan, of Fall River, for 21 years a counselor and supervising censor of the Bristol South District, at his home in Fall River on October 1st, at the age of 64. "Dr. Dolan, of Irish-Scotch ancestry, a native of Shirley, Mass., had graduated at St. Joseph's College, New Brunswick, in affiliation with Laval University, in 1879, and then from the medical department of the University of Pennsylvania, where he received his M.D. in 1882. After completing a service as house surgeon at St. Peter's Hospital, Albany, N. Y., he settled in practice in Fall River. In 1891 he was appointed medical examiner by Governor William E. Russell, holding that office at the time of the celebrated Lizzie Borden murder trial. He was a member of the school board and in 1900 was president of the Bristol South District Medical Society, the following year being elected counselor and supervising censor, the positions he filled so acceptably and faithfully for such a long period. Few meetings were held without his presence and active participation in the deliberations. He was looked up to and his judgment was valued by everyone who came in contact with him. As we saw him here—intelligent, pertinacious, unmoved by expressions of approval or disapproval, in a popular sense holding to his own, he presented an example for us all which we must always value."

The Chair announced the members of the Gorgas Memorial Committee, which he had appointed under the vote of the Society at its meeting on June 11, 1922. The names follow:

F. C. Shattuck, *Chairman*
S. B. Woodward
E. H. Stevens
F. B. Lund
W. H. Robey

He explained that according to past custom the Committee of Arrangements for the annual meeting would be called on for a statement of

the provisional plans that had been made, that standing committee in the present situation having immediate charge of the preparation of the matter for the official program and of the general arrangements in coöperation with the President, while the local arrangements would be attended to by a supplementary committee of men in Pittsfield and the surrounding territory. In the absence of Dr. K. G. Percy, chairman of the standing committee, Dr. A. P. Merrill, of Pittsfield, was called on and said that while the details of the meeting had not yet been made the work had been started and the meeting places and a part of the program outlined. The Pittsfield members wanted to have a large attendance and hoped to give an instructive and interesting meeting. They planned to send a questionnaire to all of the Fellows asking whether they would attend and how many guests they would bring with them, so that definite plans could be perfected for entertaining all that might come. The Chair thought that the meeting was sure to be a successful one and hoped that the entire society would join in efforts to make it a notable occasion. In accordance with the suggestions that had been made to him he nominated the following local Committee of Arrangements for the meeting in Pittsfield on June 12 and 13, 1923, and they were appointed, by vote:

A. P. Merrill, *Chairman*
B. W. Paddock
J. B. Thomes
C. H. Richardson
P. J. Sullivan

At the behest of the standing Committee on Publications and Scientific Papers the Secretary read a letter from Dr. Dean Lewis, of Chicago, accepting his appointment as Shattuck Lecturer for the meeting in 1923.

Dr. D. N. Blakely, Chairman of the Committee on Membership and Finance, reported for that committee on the name of General Leonard Wood, nominated for honorary membership at the meeting of the Council on June 13, 1922, and referred to his committee under the provisions of Chapter I, Section 4, of the by-laws, that the committee confirmed the nomination and recommended his election. General Wood was thereupon elected to honorary membership by a unanimous vote, by a show of hands.

Dr. Blakely then read the remaining sections of his report on membership, those numbered 2, 3, 4 and 5. Under No. 2,—those who were to be allowed to resign,—Dr. W. P. Bowers objected to the name of Philip A. E. Sheppard, of 253 Newbury Street, Boston, stating that having been connected in 1917 with the Gordon Pible College and informed by the Committee on Ethics and Discipline that it was unethical to publish advertising matter concerning that college and his connection with it, Sheppard had lately deliberately taken up the practice of

chiropractic, announcing himself on his street sign and in the telephone directory as a practitioner of that cult; then he had taken up the Abrams' cult of electronic reactions and ohms. While applying that treatment he promised to cure a young man, for a large money consideration, of so many ohms of syphilis and so many ohms of sarcoma. The matter was placed before the Committee on Ethics and Discipline and that committee saw fit to ask for Dr. Sheppard's resignation while bringing the matter to the attention of the Massachusetts Board of Registration in Medicine. That board after several hearings, at which Dr. Sheppard was represented by eminent legal counsel, revoked his license to practice in the State. Dr. Bowers thought that if the Massachusetts Medical Society stands for ethical practice it is reasonable to suppose that a man who has shown himself to be unethical should be expelled and not be allowed to resign. A somewhat similar case had come up in 1918 where an unethical practitioner had not been allowed to resign, by vote of the Council; charges had been preferred against him subsequently by the Committee on Ethics and Discipline, a trial was held and he had been expelled by vote of the Society.

Dr. E. H. Bigelow favored the remarks of Dr. Bowers. It had been an old custom in New England to clean house once a year or oftener; the robe of the Society was not broad enough to cover a man who prostitutes himself for money; he hoped the case of Dr. Sheppard would be referred back to the Committee on Ethics and Discipline. On motion by Dr. Bowers it was *voted*: That the name of Philip A. E. Sheppard,—No. 6 on the list of the Committee on Membership and Finance, to be allowed to resign,—be stricken from said list and the case recommitted to the Committee on Ethics and Discipline for another recommendation as to the status of this Fellow.

On motions by G. W. Kaan, A. N. Broughton, Lincoln Davis and E. L. Hunt the names of B. N. Bridgman, Roy Garland, W. L. Smith and A. G. Kilbourne, offered respectively, were stricken from Section 4—33 names of Fellows to be deprived for non-payment of dues—of the report of the Committee on Membership and Finance, leaving twenty-nine names. As amended the report as a whole was accepted and its recommendations adopted.

REPORT OF COMMITTEE ON MEMBERSHIP AND FINANCE AS TO MEMBERSHIP.

The Committee on Membership and Finance makes the following recommendations as to membership:

1. At the last meeting of the Council, June 13th, 1922, General Leonard Wood of the Philippine Islands was nominated for Honorary Membership in the Massachusetts Medical Society, under the provisions of Chapter I, Section 4, of the by-laws.

Your Committee confirms this nomination, and recommends his election.

2. That the following named five Fellows be al-

lowed to resign under the provisions of Chapter I, Section 5, of the by-laws:

Connor, Homer Leigh, of Omaha, Nebraska (Major M.C.U.S.A.), as of Jan. 1, 1923.

Glidden, Edson Williams of Alto, Ga. (State Sanatorium) as of Jan. 1, 1922, with remission of dues for 1920-21.

Golden, Ross, of New York City (Presbyterian Hospital), as of Jan. 1, 1923.

Jones, Basil Bradbury, of Los Angeles, Calif. (Brockman Building), as of Jan. 1, 1923.

Schank, Clara Margaret, of Boulder, Colorado (Boulder, Colorado, Sanatorium), as of Jan. 1, 1923.

3. That the following named nine Fellows have their dues remitted under the provisions of Chapter I, Section 6, of the by-laws.

4. That the following named twenty-nine Fellows be deprived of the privileges of Fellowship, under the provisions of Chapter I, Section 8, of the by-laws:

Aaronsen, Jacob, of Chelsea (286 Chestnut Street).
Adamian, Hovsep Garo, of Fresno, Calif. (2424 Ventura Avenue).

Aimone, Victor Anthony, formerly of Cambridge.

Azadian, David George, formerly of Ellsworth, Pa.

Beaudet, Elphège Aleime, of Lowell (268 West 6th Street).

Bolduc, Albert George, of Bayonne, N. J. (847 Avenue C).

Carley, Margaret Elizabeth, of Brooklyn, N. Y. (150 Columbia Heights).

Crandall, Walter Midkiff, of Northwood Narrows, N. H.

Fregau, Aime Napoleon, formerly of Fitchburg.

Greany, William Francis, of Holyoke (644 Dwight Street).

Grover, Arthur Leon, of Los Angeles, Calif. (4621 S. Gramercy Place).

Guy, Walter Bryant, of St. Augustine, Florida.

Hamblen, Howard, of South Windham, Maine.

Hegarty, Joseph Gordon, of Boston (21 Bay State Road).

Hill, Lawrence Richardson, of Concord, N. H. (48 Pleasant Street).

Kelley, Robert Edward Stack, formerly of Mattapan.

Koplin, Harry, of Los Angeles, Calif. (4408½ Monita Avenue).

Lawlor, John Charles, formerly of Dover, N. H.

MacKinnon, Donald Lauchlin, of Truro, N. S. (Prince Street).

Mahar, Harold Robert Collins, of Orange (Prospect Street).

Mayers, John Edward, of Santa Monica, Calif. (First National Bank Building, Ocean Park).

McConnell, David James, formerly of Greenfield.

McDonald, William Joseph, formerly of Brookline.

Pillsbury, Arthur Russell, of West Roxbury (C.S.P.H.).

Robertson, Jessie Wilhelmine, of Cambridge (1288 Mass. Ave.).

Scott, Norman McLean, formerly of Boston (536 Commonwealth Ave.).

Seibels, Robert Emmet, formerly of Springfield.

Stevenson, Edie Allayne, of Agnew, Calif. (Agnew State Hospital).

Whitcomb, Clarence Adelbert, formerly of Springfield.

5. That the following named seventeen Fellows be allowed to change their membership from one district society to another without change of legal residence, under the provisions of Chapter III, Section 3, of the by-laws:

Dudley, Oscar A., Wayland, from Middlesex South to Worcester.

Morrison, William R., Brighton, from Middlesex South to Suffolk.

Parker, Willard S., Watertown, from Middlesex South to Suffolk.
 Richards, Thomas K., Cambridge, from Middlesex South to Suffolk.
 Shedden, Wm. M., West Newton, from Middlesex South to Suffolk.
 Thom, Douglas A., Belmont, from Middlesex South to Suffolk.
 Wilinsky, Charles F., Allston, from Middlesex South to Suffolk.
 Wright, J. Homer, Newton Center, from Middlesex South to Suffolk.
 Maynard, Herbert E., Winchester, from Middlesex East to Suffolk.
 Brown, Lloyd T., Milton, from Norfolk to Suffolk.
 Foley, John A., Dorchester, from Norfolk to Suffolk.
 Miller, Richard H., Roxbury, from Norfolk to Suffolk.
 Myself, Philip, Roxbury, from Norfolk to Suffolk.
 Papas, Prodromos N., Brookline, from Norfolk to Suffolk.
 Phaneuf, Louis E., Brookline, from Norfolk to Suffolk.
 Richardson, Oscar, Roxbury, from Norfolk to Suffolk.
 Saeger, Ernest T., Brookline, from Norfolk to Suffolk.

D. N. BLAKELY, *Chairman*.

Reports of the committees appointed at the June meeting of the Council to consider the following petitions were read by the Secretary and each report was accepted by vote under the usual conditions: A. A. Pastene, W. A. Millet, J. Z. Naurison, J. T. Buckley, W. H. Gallagher, F. R. Tower. In the case of S. K. Pachanian it was voted to restore him provided he pay the dues for the current year within one month. In the case of H. A. Field the report recommended not accepting his petition and it was voted not to restore him.

On nomination by the President the following committees were appointed to consider petitions for restoration to the privileges of fellowship:

For T. E. A. McCurdy—S. H. Ayer, P. M. Smith, B. W. Pond.

For D. H. Shulman—Max Sturnick, W. W. Duckering, J. W. Lane.

For O. R. Fountain—N. P. Breed, W. T. Hopkins, Butler Metzger.

On nomination by the President the following were appointed a committee to audit the treasurer's accounts: R. G. Wadsworth, F. G. Balch. In the same way these were appointed delegates to the annual meeting of the Vermont State Medical Society at Burlington, October 12 and 13, 1923: A. P. Merrill, Pittsfield; E. J. Sawyer, Boston.

Dr. D. N. Blakely read the report of the Committee on Membership and Finance as to Finance. It was accepted and its recommendations adopted.

REPORT OF COMMITTEE ON MEMBERSHIP AND FINANCE AS TO FINANCE.

The Committee on Membership and Finance makes the following recommendations as to Finance:

1. That the annual assessment for 1923 be \$9.00, instead of \$10.00, as at present. This is because of the success, financial and otherwise, which has at-

tended the present management of the BOSTON MEDICAL AND SURGICAL JOURNAL, which has resulted in a material lessening of the expense of the JOURNAL to the Society.

2. That an appropriation of \$300 be made for the Committee on Maternal and Infant Welfare, to enable it to carry on the work already begun. This is to supplement the appropriation of \$350 made at the February meeting.

3. At the June meeting of the Council a letter was read from the Committee having in charge the project of a permanent memorial in Charlton, Massachusetts to Dr. William T. G. Morton, asking the Massachusetts Medical Society to cooperate with that Committee in raising funds for the memorial. Your Committee, while in general approving the plan for this memorial, is convinced that it would be inadvisable for the Society to make an exception to its usual rule, or tradition, not to make appropriations for projects of a similar nature, and, therefore, recommends that no further action be taken.

4. It appears probable that, after the bills of the current year have been paid, there will remain a substantial balance in the Treasury. Your Committee recommends that the Treasurer be authorized to transfer to the Permanent Fund such part of the balance as in his judgment shall seem advisable, to an amount not exceeding \$10,000.

D. N. BLAKELY, *Chairman*.

Reporting for the committee appointed by vote of the Society, June 14, 1922, concerning the amount of funds the Society is authorized to hold, under the terms of its charter, the Secretary read the following letter from E. P. Saltonstall, Esq., counsel of the Society:

BARRISTERS HALL, BOSTON,

September 14, 1922.

DR. JOHN W. BARTOL, *President*, and DR. WALTER L. BURRAGE, *Secretary*, Massachusetts Medical Society.

Gentlemen:

On September sixth last, Dr. Burrage sent me a copy of the proceedings of the Society at the annual meeting on June 13 and 14, 1922, and called my attention to pages 13, 50, 51, and 52, of the printed copy of the proceedings, on the last of which pages it was,

"*Moved*, that a committee be appointed, consisting of the President and Secretary, who in conference with legal counsel shall prepare a petition to the next General Court for the enactment of an amendment to Chapter 15, Section 9, of the Statutes of 1781, to bring said section into conformity with Chapter 180, Section 9, of the General Laws of Massachusetts, 1921, relating to charitable corporations, such proposed amendment to be submitted to the Council at the October meeting for approval."

I have looked into this matter with great care, and I feel very certain that no such amendment is necessary. By this I mean that the only limit to the holding of funds by the Massachusetts Medical Society is that imposed by Chapter 180, Section 9, of the General Laws of 1921, said limit being \$2,000,000.

This section is correctly printed at the bottom of page 51 and top of page 52 in the printed copy of the proceedings of the Society, June 13 and 14, 1922, heretofore referred to.

My reason for coming to this law conclusion is, as follows:

The General Laws of 1921, as you probably know, are a new codification of all the pre-existing statutes of Massachusetts. The previous codification, known as the Revised Laws, which took effect in January,

1902, by Section 8 of Chapter 125, which dealt with, "Corporations for Charitable and other purposes," and would include the Massachusetts Medical Society, limited the amount of property to be held by such corporations, "to an amount not exceeding one million five hundred thousand dollars." In 1915 the Legislature passed the following Act:

GENERAL ACTS, 1915.

Chap. 209—AN ACT RELATIVE TO THE LIMITATION OF PROPERTY OWNED BY CHARITABLE AND OTHER CORPORATIONS.

"Section 1. Every corporation heretofore organized by special act of the legislature for a purpose or purposes for which corporations may be organized under the provisions of chapter one hundred and twenty-five of the Revised Laws, and acts in amendment thereof or in addition thereto, may *despite any provisions contained in its charter*, acquire and hold real and personal estate to an amount not exceeding one million five hundred thousand dollars, in accordance with section eight of said chapter one hundred and twenty-five.

"Section 2. This act shall not be construed to limit the amount of real and personal estate which may be held by any corporation whose charter allows it to hold an amount greater than that mentioned in Section one hereof."

(The italics inserted by me.)

In 1917 the Legislature passed the following Act:

GENERAL ACTS, 1917.

"Chap. 45—AN ACT RELATIVE TO THE LIMITATION OF PROPERTY OWNED BY CHARITABLE AND OTHER CORPORATIONS.

"Section 1. Section eight of chapter one hundred and twenty-five of the Revised Laws is hereby amended by striking out the words 'one million five hundred thousand,' in the fourth and fifth lines, and inserting in place thereof the words:—two million,—so as to read as follows: Section 8. Any corporation organized under general or special laws for any of the purposes mentioned in section two, and under sections thirteen to sixteen, inclusive, may hold real and personal estate to an amount not exceeding two million dollars, which shall be devoted to the purposes set forth in its charter or agreement of association, and it may receive and hold, in trust or otherwise, funds received by gift or bequest to be devoted by it to such purposes.

"Section 2. Section one of chapter two hundred and nine of the General Acts of the year nineteen hundred and fifteen is hereby amended by striking out the words 'one million five hundred thousand' in the eighth line, and inserting in place thereof the words:—two million,—so as to read as follows:—Section 1. Every corporation heretofore organized by special act of the legislature for a purpose or purposes for which corporations may be organized under the provisions of chapter one hundred and twenty-five of the Revised Laws, and acts in amendment thereof or in addition thereto, may, despite any provisions contained in its charter, acquire and hold real and personal estate to an amount not exceeding two million dollars, in accordance with section eight of said chapter one hundred and twenty-five.

"Section 3. Nothing herein contained shall be construed to limit the amount of property that may be held by any corporation under the authority of a special act of incorporation or of any special law, whereby it is permitted to hold an amount exceeding two million dollars."

From the foregoing it is apparent that by Chapter 209 of the Acts of 1915, quoted above, the Legislature passed an Act which may be said to have been explanatory of Revised Laws, Chapter 125, Section 8,

declaring that nothing in the original charter of such corporations, limiting their power to hold funds to an amount less than \$1,500,000, should be binding upon them.

In 1917, by General Acts of 1917, Chapter 45, the Legislature raised this amount of \$1,500,000 to \$2,000,000, and again by Section 2 of that Act, stated that they might hold such a sum despite any provisions contained in their charter.

When the General Laws of 1921 were prepared, it was evidently felt by those preparing the codification, that the language of the section was sufficiently broad and definite to make it unnecessary to include the words, "despite any provisions contained in its charter" which are found in General Acts of 1917, Chapter 45.

With this history of the law I feel very safe in advising you as I have.

Article X, "Funds," of your Articles of Incorporation, which is printed in the "Digest, By-Laws, Code of Ethics and Malpractice Act of the Massachusetts Medical Society," is misleading as it now stands. It should appear at the end of that Article that it has been altered in the manner in which I have set forth in my letter.

If there is anything further which you wish me to do on this matter, or any further explanation which I can give you, do not fail to call upon me.

Very truly yours,

E. P. SALTONSTALL.

The Chair explained that counsel thought best to indicate in the "Digest" of the laws of the Commonwealth concerning the Society what the present situation as to funds is, therefore the committee had drafted a motion covering this matter. The motion was offered by Dr. H. T. Hutchins, who had brought in the motion for a committee last June; was seconded and carried unanimously.

Moved, That a statement worded as follows be printed at the end of Article X, Paragraph one, of the DIGEST of the Statutes of the Commonwealth of Massachusetts relating to the Massachusetts Medical Society:

"In the opinion of Endicott P. Saltonstall, Esq., Counsel for the Society, duly rendered September 14, 1922, to the President and Secretary,—a special committee duly acting by vote of the Society, June 14, 1922,—Section 9, Chapter 15, of the Statutes of 1781, is so far modified by Section 1, Chapter 209, of the General Acts of the year 1915, and by Sections 1 and 2, Chapter 45, of the General Acts of the year 1917, all being codified in the 'General Laws' of 1921, Section 9, Chapter 180, that the Society without amendment to its Charter, is, in common with any charitable corporation, permitted to acquire and hold real and personal estate to any amount not exceeding two million dollars, 'despite any provisions contained in its charter.'"

The committee appointed in June to arrange for a joint meeting or meetings of the State medical societies of New England, namely, Dr. J. W. Bartol, Dr. W. P. Bowers and Dr. A. P. Merrill, made a preliminary report through Dr. Bowers. He said the committee had been active in trying to ascertain the sentiment toward this project throughout New England; letters had been sent to the officers of the State medical societies and to other prominent practitioners; the replies had been almost unanimously in favor; the committee was ready to continue to function

and to ascertain the wishes of the different States and to hold a meeting in the near future of the representatives of these State societies for that purpose. On motion by Dr. J. S. Stone it was voted that the committee be continued and that the Council expresses its opinion in favor of holding such a combined meeting if possible.

Dr. H. G. Stetson, of Greenfield, read a report of the delegation from the Massachusetts Medical Society to the sessions of the House of Delegates of the American Medical Association, at St. Louis, last May (See Appendix). The report was discussed by Dr. C. E. Mongan, one of the delegates, who described some of the currents that ebbed and flowed in the House of Delegates. He thought that an error had been made in doing away with the weaker medical colleges, such as Dartmouth and Bowdoin, for now there are only five medical colleges in New England where a man can get a first-rate medical education,—not enough, to his mind, to provide practitioners for such a large territory. Such problems, affecting the whole medical profession, ought to have long consideration by authoritative medical bodies before they were acted on. He spoke also on the amendment to the constitution of the American Medical Association limiting membership in the House of Delegates, that he had proposed. It was voted to accept the report and to place it on file.

The Chair announced the officers of the new Section of Obstetrics and Gynecology that he had appointed under the terms of the vote of the Council last June: C. E. Mongan, Somerville, *Chairman*; F. C. Irving, Boston, *Secretary*.

Upon nomination by the President, Dr. C. J. Leary, of New Bedford, was elected counselor and supervising censor for Bristol South to fill the vacancy caused by the death of Dr. W. A. Dolan.

The Chair stated that at the annual meeting of the Council Dr. Croft of Franklin had presented a set of resolutions with relation to holding one or more of the meetings of the Council in Springfield or Worcester, that the expense of carfare of the councilors attending meetings of that body be paid from the treasury of the Society and that the resolutions be submitted to the eighteen district societies before final action on them be taken. The Chair hoped that there would be a definite expression of opinion on this question by the districts. The Secretary stated that thus far he had heard from only six districts, three of them being opposed to the purport of the resolutions, two in favor and one noncommittal. On being asked if he had anything to say at that time Dr. Croft said he had not.

The Standing Committee on Public Health reported through the chairman, Dr. Bigelow, on Dr. Mongan's motion as to the definition of

"public health" and "public health nurse" that had been committed to them, as follows:

Public Health.—Public Health has for its objective the promotion of the physical and mental well-being of the public, through preventive, educative or therapeutic measures.

Public Health Nurse.—A Public Health Nurse is a registered graduate nurse who is employed by, and who acts as, an agent of a statutory public health organization.

This was discussed by Dr. Mongan, Dr. E. F. Cody of Bristol South, Dr. A. H. Quessy of Worcester North, and Dr. G. M. Sheahan of Norfolk South. Dr. Mongan wondered where public health begins and private health leaves off in the consideration of the many problems of the day, notably in the matter of child hygiene and prenatal care. Dr. Cody championed the definition of the Committee on Public Health, of which he is a member. Dr. Quessy drew a distinction between community health, or public health, and the health of the individual, thinking that the former should not be allowed to trespass on the latter,—a tendency he noted in recent health legislation, a step toward social medicine. The department of labor and industry should concern itself solely with the individual, while the department of public health should have to do with the public alone, as set forth in this State by the opinion of an attorney general. Dr. Sheahan said he did not know whether the socialization of medicine was for the best or not; there were arguments on both sides. He was in favor of the views expressed by Dr. Quessy.

Adjourned at 2 P. M.

WALTER L. BURRAGE, *Secretary*.

APPENDIX TO THE PROCEEDINGS OF THE COUNCIL, OCT. 4, 1922.

REPORT OF DELEGATES FROM THE MASSACHUSETTS MEDICAL SOCIETY TO THE MEETINGS OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ST. LOUIS, MAY 22-26, 1922.

The Massachusetts Medical Society was represented at these meetings by its full quota of five delegates. In the committee appointments of the House of Delegates this Society was represented by Dr. Lund in the Committee on Medical Education, and by Dr. Stetson in the Committee on Reports of Officers.

The addresses before the House of Delegates of President Work, of President-elect de Schweinitz, and of the Speaker of the House, Dr. Warshuis, contained much of interest and of value relating to the American Medical Association, and its work, as well as to the profession at large, and collectively they bring before the Legislative Body of the American Medical Association many thoughts and beliefs looking toward the higher standards and greater broadness of the work of the medical profession as a whole, and these should be carefully read by all members of the Society.

The report of the Secretary states that the membership of the American Medical Association as of May 1, 1922, was 89,048, an increase for the year of 2,765. The Fellowship of the Association was 59,970, an increase of 2,952 in the past year.

The report of the Board of Trustees is a review of the business side of the Association, and shows the financial standing to be sound and progressive, and the capital invested to be constantly increasing. The demands upon the activities at the headquarters of the Association demand additional room, and plans have been perfected and partially carried out, providing for such increased space. A detailed financial statement accompanies the report of the Board of Trustees. One item of interest states that it is hoped and believed that the annual dues, which were increased from \$5.00 to \$6.00 in November, 1920, will be reduced to \$5.00 with the beginning of the new year.

As usual, the annual report of the Council on Health and Public Instruction, and of the Council on Medical Education and Hospitals were very complete and elucidating, and should be carefully read by those interested in present-day medical problems. The following quotation of the summary of the Council on Medical Education is worthy of repetition as illustrating some of the problems that must be met by this Council:

"The higher entrance requirements, improved medical schools, and the modern methods of teaching have created new problems in medical education. For example:

1. The necessity of limiting enrolments has made it difficult for well qualified students to secure enrolment in medical schools. It appears, however, that this difficulty is only temporary.

2. There is still ample room in Class A medical colleges for more than the total number of students enrolled in all colleges during the last session.

3. The cost of conducting medical schools under the present standards of medical education has been greatly increased. Instead of there being profits from students' fees, now the expense is two to four times the amount obtained from students' fees. The average income reported by sixty-nine medical schools is \$130,672, of which \$35,135 (26.9 per cent.) was obtained from students' fees.

4. The average expenditure of each medical school was \$123,947, including \$46,162 (37 per cent.) for all-time teachers, and \$21,131 (17 per cent.) for part-time teachers which makes 54 per cent. for instruction. The average annual fee paid by the student was \$185, and the average expense for his instruction was \$655. In 1916 the average fee was \$150, and the average expenditure was \$419.

5. Certain dangers from specialization have developed in that (a) medical schools are turning out specialists rather than thoroughly trained general practitioners, and (b) graduates are inclined to pose as specialists without first securing the essential experience or special training. The situation requires a reorganization of the undergraduate curriculum, and the requirement eventually, of evidence of special training before the physician is entitled to pose as a specialist.

6. Since the World War the lack of physicians in the smaller towns and rural communities has become more acute. It is evident that the solution of the problem is the establishing of hospitals in every center having sufficient population in the surrounding community to support a hospital.

7. A plan for the reorganization of the undergraduate curriculum calls for (a) the leaving of instruction in the specialties for the graduate school, (b) a less rigid division of the hours devoted to teaching in the various departments of the medical school, and (c) a closer correlation of clinical work with that of the so-called laboratory courses of instruction.

8. Among the acute problems of medical licensure are: (a) The licensing of graduates of low grade medical colleges by separate sectarian boards in Arkansas and Connecticut. (b) The licensing of

osteopaths as physicians in a few states, notably California, Colorado and Texas. (c) The granting of separate boards for certain groups of 'drugless' healers under a misconception of what is meant by the term 'the practice of medicine,' and (d) the importance of one standard of educational qualifications to be insisted upon alike for every one who is to be authorized to treat the sick."

As usual, a large number of resolutions were introduced in the House under the head of new business, some of which may be briefly considered. A resolution addressed to the Secretary of the Treasury and to Congress asking for a relief from the present unsatisfactory conditions attending the dispensing of alcohol for therapeutic uses by physicians, and recommending that provision be made for supplying bonded whiskey for medicinal use only at a fixed retail price to be established by the Government. A resolution addressed to those in authority having charge of the vocational training of disabled soldiers:

"To take such action in the interest of the welfare of all the people, and also for the protection of those who honestly desire to administer to the sick, to the end that the ex-soldiers seeking vocational training, which will fit them for ministering to the sick, and aiding in the recognition, control and prevention of disease, shall, at least, meet the requirements, and shall receive such adequate training as is defined in the classification of medical schools of the American Medical Association known as Class A, or acceptable medical schools—a standard which is approved by all right-thinking people moved by a desire for public welfare."

This resolution was passed, and is a modification of a resolution introduced at the request of the St. Louis Medical Society, stating that in the Ninth District, comprising the states of Missouri, Iowa, Kansas and Nebraska, there were enrolled in one Chiropractic School in Missouri more than 250 disabled ex-soldiers from all parts of the country, with the sanction and approval of the Government.

The definition of State Medicine this year, as last, called forth several attempts at its solution, no less than five such resolutions being introduced by different members of the House. The Reference Committee on Legislation and Public Relations finally recommended for adoption the following:

"The American Medical Association hereby declares its opposition to all forms of 'state medicine,' because of the ultimate harm that would come thereby to the public weal through such form of medical practice.

"State medicine' is hereby defined for the purpose of this resolution, to be any form of medical treatment, provided, conducted, controlled or subsidized by the federal or any state government, or municipality, excepting such service as is provided by the Army, Navy or Public Health Service, and that which is necessary for the control of communicable diseases, the treatment of mental disease, the treatment of the indigent sick, and such other services as may be approved by and administered under the direction of or by a local county medical society, and are not disapproved by the state medical society of which it is a component part."

And this resolution was passed.

An amendment to the constitution was proposed which called forth much discussion, and was laid upon the table for one year, in accordance with the rules of the House. The amendment asked for reads as follows:

"Section 2.—Composition.—The House of Delegates is composed of delegates selected by the constituent associations, and of delegates from the Medical Departments of the Army and Navy, and the Public Health Service, appointed by the Surgeon-General of the respective departments, and of

section-delegates elected by the sections of the scientific assembly.

The section-delegates shall have the privilege of the floor, but only the right to vote on matters directly affecting the activities of the sections. The trustees shall be ex officio members of the House of Delegates, but without the right to vote.

Section 3. The total unrestricted voting membership of the House of Delegates shall not exceed 150. The Medical Departments of the Army and the Navy, and the United States Public Health Service shall each be entitled to one delegate, and the remainder shall be apportioned among the constituent associations in proportion to their actual membership as hereinafter provided in the By-Laws. The scientific sections shall each be entitled to one section-delegate. Should the right of the section delegate to vote be challenged on a question before the House, decision shall be made by a ruling of the Speaker, subject to the approval of the House."

This amendment, if adopted, would do away entirely with members of the House of Delegates representing the various sections with voting power, 15 in all. The principal argument offered for the passage of this amendment was the statement that certain sections were receiving double representation, of which the state of Illinois was one example. This state is entitled to nine delegates. In addition to the nine delegates from the Illinois State Medical Society, it was represented by five of its members as delegates from the various sections, making the Illinois delegation in the House of Delegates fourteen instead of its allotted nine. On the other hand, many of the most active and influential members of the House of Delegates are the representatives of the various sections—men of experience and of considerable length of service in the legislative branch of the Association, and their withdrawal would be a distinct loss to the personnel of the House. Naturally there was much discussion regarding this resolution, and the end is not yet, as its final settlement in San Francisco in 1923 will not unlikely be preceded by something of an oratorical struggle.

The Sheppard-Towner law came in for its share of discussion, and was finally disposed of through the following resolution:

"Whereas, The Sheppard-Towner law is a product of political expediency, and is not in the interest of the public welfare, and

Whereas, the Sheppard-Towner law is an imported socialistic scheme unsuited to our form of government, and

Whereas, The Sheppard-Towner law unjustly and inequitably taxes the people of some of the states for the benefit of the people of other states for purposes which are lawful charges only upon the people of the said other states, and

Whereas, The Sheppard-Towner law does not become operative in the various states until the states themselves have passed enabling legislation, therefore be it

Resolved: That the American Medical Association disapprove the Sheppard-Towner law as a type of undesirable legislation which should be discouraged."

The House approved the recommendation of the Board of Trustees relative to Public Health Activities of the American Red Cross, stating their belief that appropriate action should be taken to convince those in authority that the Public Health Activities of the American Red Cross are no longer necessary, and it continued are likely to promote community responsibility and helplessness in regard to its welfare. The House further voted that the Board of Trustees be instructed to take such action as will make this recommendation effective at the earliest possible moment. It is felt by the Trustees and by the House of Delegates as well, that much of the

work now being carried on by the American Red Cross can be taken care of by local and county medical organizations with much less dissatisfaction.

The question of Pay Clinics, Diagnostic Clinics, and Group Practice was brought to the attention of the House by the Board of Trustees, and the House voted that a survey be made of these clinics, such survey to be conducted jointly by the Judicial Council and the Council on Medical Education and Hospitals, with the request that their reports and recommendations be submitted to the next annual meeting of the House in San Francisco in 1923.

It was voted that the Trustees be authorized to establish a central bureau for the consideration of legislation, both national and state, in so far as such legislation pertains to medicine, or the practice of medicine, and the public health, such a central bureau to coordinate the activities of the several constituent state associations to ascertain and crystallize the opinions of the medical profession, and to represent the American Medical Association as a body.

The advisability of dividing the American Medical Association into districts was taken up on the suggestion of the President of the Association, Dr. Work, these several districts to be represented in the Board of Trustees by a Trustee, and in addition to the large, general meeting held yearly, that similar meetings be held in each district, preferably during the winter months. This matter was considered by the Reference Committee on Reports of Officers, who recommended that in view of the enormous scope and the great importance of this question, that the House direct the appointment by the President of a special committee to consider the matter, and report to the House of Delegates at the annual meeting in 1923.

The New England States have been very consistent for many years in reappointing their State Association delegates to the meetings of the American Medical Association. The wisdom of this custom is very noticeable in the work in the House of Delegates. The New England delegation has come to be looked upon as a group of capable, judicious, influential members, and as a delegation from one section of the country it is without question a group of men standing for the best things in medicine, and it is so considered in the House.

Respectfully submitted,

H. G. STETSON,

For the Delegates of the Massachusetts Medical Society.

Book Review.

Stedman's Medical Dictionary. Seventh Edition. By THOMAS LATHROP STEDMAN. 1144 pages, xv plates. Price \$7 net.

Stedman's Medical Dictionary has now reached its seventh edition. It is of convenient size for desk work and is a good example of the printer's art. There are several notable additions to be found in the appendix, such as plates showing the eggs of human parasites, changes in the morphology of the blood, the differential diagnosis of scarlet-fever as shown on the surface and on mucous membranes, protozoan parasites, and diagrams of anatomic structures. This book is of value to all interested in medical subjects and should be of assistance to writers of articles. It is published by William Wood & Co.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

ENTER DR. ABRAMS.

A RECENT issue of the JOURNAL[®] contained an editorial on "The Electronic Reactions of Abrams," in which was set forth an outline of the method employed by Dr. Abrams in diagnosing disease from a few drops of blood. The editorial pointed out certain fundamental defects in the method, and showed the impossibility of the conduction by Abrams' apparatus of any sort of electromagnetic current or radioactivity known to man. Further study of the subject was handicapped by the lack of opportunity to witness the method in operation. The local Abrams representative refused to run a series of test cases under any conditions.

Then, most opportunely, Abrams himself came to Boston. On Sunday afternoon, October 8th, he delivered a lecture at the Copley Plaza, at which between 800 and 1000 persons were present. On Monday afternoon, he appeared before the Board of Registration in Medicine at an informal hearing, prepared, as the Board was led to believe, to give a demonstration of his method. Opportunity had been given a representative of the practitioners of the Electronic method to inspect the room and to arrange for proper wiring, but when the meeting was called to order Dr. Abrams said it was impossible to give a demonstration then. Instead, he and

his followers started to hold an "experience meeting" in which they might testify to the efficiency of the method. Dr. Prior, chairman of the Board, acting with dignity and firmness, refused to listen to such a recital. The meeting was adjourned. The next day—Tuesday, October 10—pursuant to an invitation extended by him, Dr. Abrams gave a clinical demonstration of his method in the laboratory of one of his disciples. He first attempted to demonstrate simple phenomena based upon his theory of Electronic Reactions. It was a remarkable coincidence that the reactions were clearly visible or audible to those followers of his who were in the rear of the room, but were quite imperceptible to those members of the Massachusetts Medical Society who were there to look into the method and who occupied chairs close to the demonstration. Dr. Abrams consistently refused to submit his method to any test offered by those present, and confined himself to demonstrating the presence of lesions, the existence of most of which could be proved only by post-mortem examination. He selected for his experiment a member of the JOURNAL staff, a man in apparently perfect health. Yet this individual, according to Abrams, presented the following pathological conditions: Streptococcus infection of the left frontal sinus and of the right antrum; two ohms of tuberculosis, location, intestinal tract; congenital syphilis; sarcoma, non-metastatic, of the intestine. In demonstrating the situation of the sarcoma, Abrams located it first in the right lower quadrant and later, by another method, in the left lower quadrant.

Analysis of the results of Dr. Abrams' statements and demonstrations while in Boston shows two outstanding facts. First, he persistently refused to submit his method to a scientifically controlled test, or to a demonstration given under such conditions that the investigation of the method could be carried on under the usual rules of scientific criticism. Second, in the one case upon which he did demonstrate his method, he found the existence of four diseases—syphilis, tuberculosis, sarcoma, and streptococcus infection—in an individual entirely free from symptoms of any disease whatever. If, by his method, he could diagnose disease where no symptoms existed, he surely should have been able to approach without fear of failure a test based upon the diagnosis of blood specimens from a patient with well-marked clinical pathology. The fact that he refused to perform such a test is capable of only one interpretation—that is, that he knew full well his inability to make a really correct diagnosis.

The marvelous "cures" reported by himself and his followers must be explained on the ground of mental suggestion. Abrams gave this away when he said in his Sunday lecture that "if the patient will convince himself that he has no disease, I cannot elicit a reaction."

Abrams says that his Electronic Reactions are either the greatest miracle of the age or the greatest fake. No one who witnessed his demonstration and who listened at all critically to his vague explanation of the theory of these reactions could concede the former. Whether the thing is a conscious hoax or is a case of self-deception we cannot say. Whichever it is, it is dangerous doctrine; the time has come for the Board of Registration in Medicine to put a stop to the further perpetration of this fraud.

INSULIN IN THE TREATMENT OF DIABETES.

THE *New York Times* asserts that the use of Insulin in diabetes has been studied by officials of the Carnegie Corporation, and that an appropriation has been made for research work at the Potter Metabolic Laboratory and Clinic in California. It is claimed in this article that benefit has followed the use of this drug in practically all cases under observation. Dr. Pritchett will incorporate in the annual report of the corporation an account of the work carried on in California. Several remarkable cases are referred to in support of the claims.

This treatment was referred to in the Shattuck Lecture, delivered by Dr. Joslin in June, and is being used in Boston at the present time. To Dr. J. J. R. Macleod of Toronto belongs the honor of bringing this treatment to the attention of physicians.

The scientific spirit shown is in marked contrast with the claims often made by pseudo-scientists.

The *Times* also publishes reference to a gift of a large residuary legacy under the will of Mrs. Sarah L. Winchester to the General Hospital Society of Connecticut.

THE MEETING OF THE AMERICAN COLLEGE OF SURGEONS.

PRESENT indications tend to show that the meetings of this Association, October 23rd to 27th inclusive, will be one of the most important in its history.

Its membership includes over two thousand representative surgeons, and since Boston has always enjoyed the reputation of being a liberal host, a large attendance is expected.

The College took upon itself the task of standardizing surgical teaching and practice so far as it may be possible to accomplish these ends. It has dealt wisely and conservatively with the problems involved. To some it has appeared that too much conservatism has been in evidence in some ways, and an undue liberality in others. These opinions, however, might be applied to any movement designed to correct

abuses and place service for the people on higher planes. Taken all in all, a great deal has been accomplished, for, as a result of the work of the College, surgery occupies a position of greater dignity in the estimation of the public than ever before in history.

The presidential address is looked forward to with great interest, because it is expected that important policies will be outlined which will have distinct bearing in the future plans of the College.

The standards already set, and the results achieved should have a great influence on the public mind, for in the last analysis the people are the ones most concerned in medical progress. The College can work within the profession to make surgery the efficient servant of the people, but in the end the public must set legal standards for the practice of surgery for its own protection. The present legal standards only call for mediocrity. Surgery is a specialty in medicine calling for extraordinary experience and mental endowment. The results of surgery may be beneficial or tragical. The College may directly or indirectly lead to the adoption of legal requirements and restrictions relating to the practice of surgery. It is in a position to mold public opinion, and should accept the responsibility of leadership.

IMMUNITY CONFERRED BY THE SCHICK TEST.

In an article dealing with diphtheria, published in the Bulletin of the Chicago School of Sanitary Instruction under date of September 30, 1922, the following assertion appears: "If it (the test) shows that he can catch diphtheria, a life-long protection can be given him by these injections one week apart," etc. The statement is, however, modified in the next paragraph as follows: "Six months after giving the third injection of this medicine (referring to toxin-antitoxin) a second test is made just like the first test. This is to make sure the child is protected." These excerpts are taken from a letter distributed to parents in Chicago.

The question comes to mind whether we are in a position to speak so positively about any remedial agent. Over-confidence and too strong assertions are often unwise. There are too many exceptions to the rules in medicine.

NEWS ITEMS.

WEEK'S DEATH RATE IN BOSTON.—During the week ending October 7, 1922, the number of deaths reported was 208, against 170 last year, with a rate of 14.20. There were 30 deaths under one year of age, against 25 last year. The number of cases of principal reportable diseases were: Diphtheria, 51; Scarlet Fever, 33; Measles, 19; Whooping

Cough, 47; Typhoid Fever, 11; Tuberculosis, 41. Included in the above, were the following cases of non-residents: Diphtheria, 11; Scarlet Fever, 7; Measles, 1; Typhoid Fever, 3; Tuberculosis, 14. Total deaths from these diseases were: Diphtheria, 1; Whooping Cough, 4; Tuberculosis, 19. Included in the above, were the following cases of non-residents: Tuberculosis, 3.

APPOINTMENTS AT THE HARVARD MEDICAL SCHOOL.—During Dr. David L. Edsall's absence abroad, Dr. Worth Hale, Assistant Dean, will serve as Acting Dean, and Dr. Roger I. Lee has been appointed to the position of Acting Dean of the School of Public Health.

JOHNS HOPKINS HOSPITAL.—Dr. John M. T. Finney will fill the position made vacant by the death of Dr. Halsted until the faculty shall have made a selection of a permanent successor.

INVESTIGATION INTO THE CAUSE OF CANCER.—Boston is the place assigned for the work to be conducted by Dr. J. W. Scherechewsky, Assistant Surgeon General, U. S. Public Health Service, under the authority of the Treasury Department.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY.—The Semi-annual meeting of the Society was held at the Boston Medical Library, 8 The Fenway, on Wednesday, October 11, 1922, at 12 o'clock noon. Dr. Channing Frothingham of the Peter Bent Brigham Hospital read a paper on "The Relations of Osteopathy and Chiropractic to the Medical Profession." Lunch was served.

NEW ENGLAND SOCIETY OF PSYCHIATRY.—The semi-annual meeting of the New England Society of Psychiatry was held with Dr. R. Leighton Leak, Superintendent, at the Connecticut State Hospital, Middletown, Conn., Thursday, October 5, 1922.

In the absence of the President, Dr. Walter E. Fernald, Dr. E. B. Lane presided. Fifty-two members were present.

Program: "Endocrinology and Psychiatry," Dr. Walter Timme, New York. "Modern Trends in Psychiatry," Dr. Frankwood E. Williams, New York.

A NEW OFFICE IN THE NEW ENGLAND SURGICAL SOCIETY.—At the annual meeting in Burlington, Dr. John B. Blake was elected to the office of Recorder of the Society. Members will confer with Dr. Blake about the publication of papers and reports of discussions. This action was taken in order to relieve the Secretary, who has been obliged to work under the disadvantages incident to living away from Boston.

Miscellany.

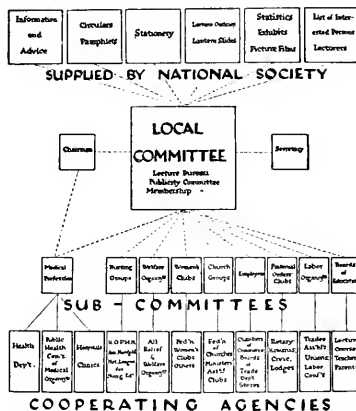

CANCER WEEK.

Under Campaign Notes the prime essentials for cancer week of 1922 are outlined as follows:

1. Written Articles.
2. Motion Picture Theatres.
3. Scientific Meetings and Public Lectures.

Mr. Van Ness Harwood has been employed to conduct the publicity campaign. Short cancer articles will be published in the principal newspapers of the United States and Canada.

The following scheme for the organization of a cancer committee has been suggested:

In this plan of organization, the Central Committee is to be thought of as a group of men and women each of whom is chairman of the sub-committees appointed by him or her to carry on the educational work with a particular group or class of persons. In this way an equitable division of labor is attained. The Chairman of the Committee will be a physician, the Secretary has usually been an interested woman. The success of the Committee's work, where the plan is followed, is conditioned by the energy, tact and selflessness of the chairmen of the various sub-committee.

1922 HEALTH CHRISTMAS SEAL SALE.

QUOTAS SHOULD BE SET NOW.

ALL organizations in the state are asked again this year to set their own quotas. The National quota, as ratified by representatives of state organizations, is five million dollars. Massachusetts' share to raise is not less than \$200,000. The real quota for the state, of course, will not be \$200,000, but it will be the sum total of quotas of the local associations of the state. Last year this figure was \$242,831. In order to actually reach our \$200,000 goal in Massachusetts, it will be necessary for our better organized territory to set for themselves quotas of not less than ten cents per capita, and no organization should set for itself a quota of less than six cents per capita.

It is recognized by our organizations throughout the country that the decline in returns from the Seal Sale during the past two years must be checked. It is believed that this can be accomplished by taking advantage of improving business conditions, and by beginning to organize earlier this year than has been done heretofore in most communities.

CLINICAL CONGRESS OF AMERICAN COLLEGE OF SURGEONS AT BOSTON.

PROGRAM FOR EVENING MEETINGS.

Presidential Meeting, Monday, October 23—Symphony Hall, 8 P. M.

Address of Welcome: Lincoln Davis, M.D., Boston, Chairman of Committee on Arrangements.

Address of the retiring president: John B. Deaver, M.D., Philadelphia.

Introduction of foreign guests: Raffaele Bastianelli, M.D., F.R.C.S. (Hon.), Rome; Francis Seymour Kidd, M.Ch., F.R.C.S., London; Andrew Fullerton, C.B., C.M.G., Belfast; Einar Key, M.D., Stockholm.

Inaugural Address: Harvey Cushing, M.D., Boston. The Doctor John B. Murphy Oration in Surgery—"Surgery of the Joints": Raffaele Bastianelli, M.D., F.R.C.S. (Hon.), Rome.

Tuesday, October 24—Jordan Hall, 8 P. M.

Einar Key, M.D., Stockholm: Treatment by Embolization of Circulatory Disturbances in the Extremities Due to Emboli.

Symposium: Genito-Urinary Surgery.

Hugh H. Young, M.D., Baltimore: Prostatectomy—Preparatory, Operative, and Postoperative Methods.

Francis Seymour Kidd, M.Ch., F.R.C.S., London: Simple Mesodermal Tumors of the Urinary Bladder; with the Report of a Case Treated by Operation.

Andrew Fullerton, C.B., C.M.G., Belfast: A Note on Unilateral Duresis.

J. Bentley Squier, M.D., New York: The Surgery of Vesical Neoplasms.

Discussion: William C. Quinby, M.D., Boston; Alexander Randall, M.D., Philadelphia; John T. Geraghty, M.D., Baltimore; John H. Cunningham, M.D., Boston.

Wednesday, October 25—Jordan Hall, 8:30 P. M.

Special Meeting of the Boston Surgical Society.

Introductory Remarks: Robert W. Lovett, M.D., Boston, President.

Presentation of Henry J. Bigelow Medal to William Williams Keen, M.D., Philadelphia.

"Sixty Years Ago—1862 to 1922": William Williams Keen, M.D., Philadelphia.

Thursday, October 26—Jordan Hall, 8 P. M.

Symposium: Carcinoma of the Jaws, Tongue, and Cheeks and Lips.

George W. Crile, M.D., Cleveland: General Principles Involved in Operations: Summary of Results Obtained in the Crile Clinic, with Special Reference to Treatment of Carcinoma of the Jaws.

Edward S. Judd, M.D., Rochester, Minn.: Summary of Results Obtained in the May Clinic, with Special Reference to Treatment of Cancer of the Tongue.

George E. Brewer, M.D., New York: Summary of Results Obtained in the Presbyterian, Memorial, and

Roosevelt Hospitals of New York, with Special Reference to Treatment of Cancer of the Cheeks and Lips.

Discussion: Robert B. Greenough, M.D., Boston; Albert J. Oschner, M.D., Chicago; Vilray P. Blair, M.D., St. Louis; Joseph C. Bloodgood, M.D., Baltimore; Douglas Quirk, M.D., New York; George P. Muller, M.D., Philadelphia; Harvey R. Gaylord, M.D., Buffalo; Alexander E. Garrow, M.D., Montreal; Channing C. Simmons, M.D., Boston.

Friday, October 27—Symphony Hall, 8 P. M.

Convocation of the American College of Surgeons.

Invocation: Reverend Doctor Alexander Mann, Boston.

Conferring of Honorary Fellowships.

Presentation of Candidates for Fellowship.

Presidential Address: Harvey Cushing, M.D., Boston.

Fellowship Address: Raffaele Bastianelli, M.D., F.R.C.S. (Hon.), Rome.

HOSPITAL CONFERENCE.

Monday, October 23, in Jordan Hall.

Morning Session, 9:00 to 12:30.

John B. Deaver, M.D., F.A.C.S., President, Presiding.

Report on the Standardization Activities of the College in 1922: Franklin H. Martin, M.D., F.A.C.S., Director-General, American College of Surgeons.

The Doctor and the Hospital: Frederic A. Washburn, M.D., Superintendent, Massachusetts General Hospital, Boston.

The Minimum Standard and Its Application to Hospitals: Frederick W. Slobe, M.D., Hospital Standardization Department, American College of Surgeons.

What Real and Lasting Benefit Has Come to the Patient from Hospital Standardization?: Charles B. Mouliner, S.J., President, Catholic Hospital Association.

The American Hospital: A. R. Warner, M.D., Executive Secretary, American Hospital Association.

Hospital Standardization from a Public Health Standpoint: D. A. Craig, M.D., Provincial Commissioner, Nova Scotia Division, Canadian Red Cross, Halifax, Nova Scotia.

Hospital Standardization from the Viewpoint of the Medical Staff: R. A. Hughes, M.D., Moncton, New Brunswick.

Side-lights on Hospital Standardization: Robert Jolly, Superintendent, Baptist Hospital, Houston, Texas.

The Analysis of End-Results: Eugene H. Pool, M.D., F.A.C.S., New York, and E. A. Codman, M.D., F.A.C.S., Boston.

General Summary of Hospital Standardization: Malcolm T. MacEachern, M.D., C.M., Director-General, Victorian Order of Nurses for Canada.

Afternoon Session, 2 to 4:30—General Round Table Discussion.

Conducted by Malcolm T. MacEachern, M.D., C.M.

The Round Table Discussion will be confined largely to the requirements of the Minimum Standard. Hospital superintendents, staff members, and members of boards of trustees are urged to send in questions which they desire to be answered, in order that the discussion may shed light on the various difficulties encountered. After representative speakers have opened the discussion of these questions, the subsequent discussion will be open to all. A tentative list of the topics to be considered follows:

I. Staff organization:

1. The selection of the exact type of staff organization best suited to local needs.
2. The division of responsibility into representative committees.
3. The initial organization of the staff conference.
4. The agenda and detailed description of the staff conference.
5. Methods of stimulating interest and enthusiasm in staff conferences.
6. Monthly analysis of hospital work.

II. Case Records:

1. The component parts of a case record.
2. Methods of securing the records.
3. Methods of stimulating increased interest in the records.
4. The hospital historian or record clerk.
5. Filing systems, card indices, disease nomenclatures, and follow-up systems.

III. Laboratories and X-ray facilities:

1. Methods of stimulating increased use of laboratories by the medical staff.
2. Relationship of laboratory charges to laboratory service, and the various systems of laboratory charges commonly employed.
3. The extent to which routine laboratory examinations should be employed.
4. Laboratory facilities in the small hospital.
5. Laboratory reports and filing systems.
6. What should constitute the complete service in an X-ray department?
7. The interpretation of X-ray plates by roentgenologist versus interpretation by individual physicians.
8. To what extent can X-ray facilities outside of the hospital be used satisfactorily?

IV. Miscellaneous:

1. What points in particular should the hospital surveyor investigate in making his annual visit?
2. Making the public understand the value of hospital standardization.
3. Methods of increasing the efficiency of the hospital survey of the College.

It should be clearly understood that all are urged to take part in the Round Table. Including the speakers of the morning program, the following names are a partial list of those who have been invited to lead in the discussion:

John G. Bowman, Chancellor, Pittsburgh University, Pittsburgh.
 Pliny O. Clark, President, Protestant Hospital Association.
 H. E. Webster, Superintendent, Royal Victoria Hospital, Montreal.
 W. C. Rappleye, Rockefeller Foundation.
 Horace G. Wetherill, M.D., F.A.C.S., Denver.
 Brigadier General C. E. Sawyer, M.C., U.S.A.
 Joseph B. Howland, M.D., Superintendent, Peter Bent Brigham Hospital, Boston.
 George W. Swift, M.D., F.A.C.S., Seattle.
 E. T. Dillon, M.D., F.A.C.S., Los Angeles.
 Roy C. Kingswood, M.D., London, Ontario.
 Rev. Newton E. Davis, Executive Secretary, Conference Board of Hospitals and Homes of Methodist Church.
 Matthew O. Foley, Managing Editor, Hospital Management, Chicago.
 S. S. Goldwater, M.D., Superintendent, Mt. Sinai Hospital, New York City.
 Joseph J. Weber, Editor Modern Hospital, Chicago.
 Frank E. Chapman, Superintendent, Mt. Sinai Hospital, Cleveland.

Henry M. Pollock, M.D., Superintendent, Massachusetts Homeopathic Hospital, Boston.

R. M. Harbin, M.D., F.A.C.S., Rome, Georgia.

Charles A. Gordon, M.D., F.A.C.S., Brooklyn.

John M. Baldy, M.D., F.A.C.S., Philadelphia.

A. K. Haywood, M.D., Superintendent, Montreal General Hospital, Montreal.

PRELIMINARY CLINICAL PROGRAM.

MASSACHUSETTS GENERAL HOSPITAL.

Tuesday, October 24.

C. A. Porter, G. W. W. Brewster, R. B. Greenough, Hugh Williams, and associates—9. General surgical operations.

Surgical Staff Clinic—2. C. A. Porter, J. H. Means, E. P. Richardson, and G. W. Holmes—Surgery of the thyroid gland. T. W. Harner—Tendon surgery. Chester Jones—Bile analysis. D. F. Jones—Cancer of the bladder. W. J. Mixer, J. E. Ayer, and John S. Hodgson—Neurological surgery. C. L. Scudder and H. F. Hewes—Chronic gastric ulcer. Both Vincent—Plastic surgery. Wynnan Whittemore—Surgery of the lung.

Wednesday, October 25.

Orthopedic operations and demonstrations—9. Smith-Petersen—Arthrodesis of sacro-iliac joint. M. H. Rogers—Arthrodesis of hip joint. Z. B. Adams—Reduction of congenital dislocation of the hip. R. B. Osgood—Excision of semilunar cartilage or excision of knee joint. P. D. Wilson—Syme amputation. L. T. Brown—Spinal fusion. R. N. Hatt—Stoefel operation for spastic paraplegia. Z. B. Adams—Keller's operation for hallux valgus.

Demonstration of Orthopedic Cases—2. P. D. Wilson—Results of Syme amputation, apparatus. R. B. Osgood—Multiple myeloma; report of cases with pathological specimens. E. G. Brackett—Orthopedic surgery in China. Smith-Petersen—Correction of deformities of the hip by arthrodesis, results. Mark H. Rogers—Results of treatment of intractable sciatica by arthrodesis of the sacro-iliac joint. Z. B. Adams—Possibility of reducing congenital dislocation of the hips in children over seven. L. T. Brown—Results of operative treatment of tuberculosis of the spine in adults. J. E. Goldthwait—Physical development in military training camps.

Thursday, October 26.

D. F. Jones, Lincoln Davis, E. P. Richardson, and associates—9. General surgical operations.

Staff Clinic: Symposium on Malignant Diseases—2. R. B. Greenough—Malignant disease, introductory remarks. D. F. Jones—Cancer of the rectum. R. B. Greenough—Cancer of the breast. D. C. Green—Cancer of the antrum. Lincoln Davis and G. A. Leland—Cancer of the uterus. Channing Simmons—Osteogenic sarcoma. G. W. Holmes—X-ray as a prophylactic and in palliative treatment. H. P. Mosher—Cancer of the esophagus. C. L. Scudder and H. F. Hewes—Cancer of the stomach.

Friday, October 27.

R. B. Greenough and D. F. Jones—9. General surgical operations. J. D. Barney and associates—11. Genito-urinary operations.

Surgical Clinic by Staff—2. J. D. Barney—Pneumocystography as an aid in diagnosis. G. C. Smith—Treatment of cancer of the penis. R. F. O'Neill, E. G. Crabtree—Surgical approach of the lower end of the ureter. H. H. Crabtree—Experiences with stone in the lower ureter. G. G. Jones—Methods of demonstrating tubercle bacilli in the urine. D. F. Jones and associates—3:45. Standardized treatment of frac-

BOSTON CITY HOSPITAL.

Tuesday, October 24.

F. B. Lund—9. General surgical operations. E. B. Young—9. Gynecological operations. J. C. Hubbard and associates—2. Dry clinic (general surgery). O. J. Herman—2. Intestinal gunshot wounds. E. B. Young and associates—2. Series and results in miscarriages. G. L. Vogel and associates—2. Ear and throat cases. L. M. Freedman—2. Carcinoma of soft palate and larynx. E. J. Monahan—2. Tonsillectomy in acute disease.

Wednesday, October 25.

J. C. Hubbard and associates—9. General surgical operations. G. L. Vogel and associates—9. Ear and throat operations. E. B. Lund—2. Demonstrations: carcinoma of stomach; carcinoma of tongue; facial nerve anastomosis; results of operation. I. J. Walker—2. Echinococcus cyst of liver; resection of stomach, three cases; oral cancer, radium, three cases. Stephen B. Mallett and W. H. Canavan—2. Cases of dental surgery.

Thursday, October 26.

H. A. Lothrop and associates—9. General surgical operations. Paul Thorndike and associates—9. Genito-urinary operations. F. J. Cotton and associates—2. Demonstrations: operation for recurrent dislocation of shoulder; series of cases of artificial ligaments in loose knees; arthroplasty, Putti technique; operation for flat-foot, new technique; pelvic fracture cases; Colles fracture results. P. F. Butler and A. W. George—2. Surgical X-rays.

Friday, October 27.

F. J. Cotton and associates—9. General surgical operations. H. A. Lothrop and associates—2. Demonstration of surgical cases. Horace Binney—2. Gangrene of the lung; abscess of the lung; separation of the lower epiphysis of the femur; certain type of fracture of the forearm. A. R. Kempton—2. Tumor of the carotid body. H. B. Stevens and associates—2. Ophthalmic surgery. J. J. Corbett—2. Series of cataract operations.

CHILDREN'S HOSPITAL.

Tuesday, October 24.

R. W. Lovett and associates—9. Orthopedic operations.

Surgical Staff Clinic—9. W. E. Ladd—Harelip cases (with lantern slides). C. G. Mixer—Undescended testicle. J. S. Stone—Pneumococcus peritonitis; omphalic tumors. G. D. Cutler—Teratoma; webbed fingers. T. H. Lauman—Hemangiomas. J. S. Stone and associates—2. General surgical operations.

Orthopedic Staff Clinic—2. Robert Soutter—Obstetrical paralysis. A. T. Legg. Pathology and treatment. J. W. Sever. J. H. Fitzsimmons. Clubfoot. R. F. Ober. Treatment and operative means.

Wednesday, October 25.

R. W. Lovett and associates—9. Orthopedic Clinic; Fractures of the spine in industrial accidents; results of stabilizing operations for weak or flail joints in poliomyelitis. F. R. Blumenthal—9. Cases of orthodontia. J. S. Stone and associates—9. General surgical operations. R. W. Lovett and associates—2. Orthopedic operations.

Surgical Staff Clinic—2. Bronson Crothers. Injuries of spinal cord in childbirth. George D. Cutler. Meningocele. James S. Stone. Spina bifida occulta. William E. Ladd. Megacolon. Charles G. Mixer. Congenital defect of bile ducts.

Thursday, October 26.

R. W. Lovett and associates—9. Orthopedic operations.

Surgical Staff Clinic—9. T. H. Lauman—9. Skin grafts. W. E. Ladd—9. Cases of plastic surgery. G. D. Cutler—9. Ruptured kidney. C. G. Mixer—9. Tumors of the kidney; chronic pyelitis. James S. Stone and Oscar M. Schloss—9. Typhoid stenosis and spasm. D. Crosby Greene—9. Cases of laryngeal and esophageal stricture. J. S. Stone and associates—2. General surgical operations. R. W. Lovett and associates—2. Orthopedic clinic; Congenital dislocations of hip, results of operative treatment; Legg-Calvé disease, pathology and treatment; relief of contracture of the hip.

Friday, October 27.

J. S. Stone and associates—9. General surgical operations. R. W. Lovett and associates—9. Orthopedic clinic; Infantile paralysis, results in treatment clinic; muscle and tendon transplantation, the result of treatment; transplantations of the tensor fasciae femoris for paralysis of the abductors. R. W. Lovett and associates—2. Orthopedic operations.

Surgical Staff Clinic—2. W. E. Ladd—Intussusception. C. G. Mixer—Intestinal obstruction. G. D. Cutler—Intestinal obstruction by Meckel's diverticulum. J. S. Stone and O. M. Schloss—Atypical cases of appendicitis in children; differential diagnosis.

MASSACHUSETTS HOMEOPATHIC HOSPITAL.

Tuesday, October 24.

J. Emmons Briggs and W. S. K. Thomas—3. Surgery of the stomach, operations. D. W. Wells and associates—9. Operations on the eye. A. G. Howard—9. Orthopedics. Conrad Smith—9. Nose and throat clinic. D. W. Wells—9. Eye clinic. S. W. Ellsworth—9. Lesions of the gastro-intestinal tract. C. T. Howard and W. S. K. Thomas—2. General surgical operations. A. W. Rowe and W. L. Mendenhall—2. Vital function tests in relation to surgery.

Wednesday, October 25.

T. E. Chandler and H. J. Lee—9. Gynecological operations. Conrad Smith. E. R. Johnson, and C. W. Brush—9. Nose and throat operations. A. G. Howard—9. Demonstration; back strain. T. E. Chandler and H. J. Lee—2. Gynecological operations. A. S. Regg and F. H. Pratt—2. Anatomical and physiological demonstrations.

Thursday, October 26.

C. T. Howard and Clarence Crane—9. Surgery of the biliary tract. F. W. Colburn and H. L. Babcock—9. Operations on the ear. A. G. Howard—9. Orthopedics. Conrad Smith—9. Nose and throat clinic. S. W. Ellsworth—9. Demonstration: Some points in differential diagnosis of diseases of bones. J. Emmons Briggs and Clarence Crane—2. General surgery; operative clinic. W. H. Watters—2. Clinic-pathological conference and medico-legal autopsy. D. L. Belding—2. Wassermann tests in surgical diagnosis. S. B. Hooker—2. The necessity for adequate compatibility tests preliminary to blood transfusion. Helmuth Ulrich—2. Blood tests in surgery.

Friday, October 27.

A. G. Howard—9. Orthopedic operations. D. W. Wells—9. Eye clinic. R. C. Wiggin—2. Genito-urinary surgery; operative clinic.

FREE HOSPITAL FOR WOMEN.

Tuesday, October 24.

W. P. Graves, F. A. Pemberton, and R. G. Wadsworth—9. Gynecological operations.

Wednesday, October 25.

W. P. Graves and F. A. Pemberton—9. Gynecological operations. W. P. Graves—2. Clinic on proclivity; radium and cancer of the uterus.

Thursday, October 26.

W. P. Graves, F. A. Pemberton, and H. W. Baker—9. Gynecological operations. F. A. Pemberton—2. Clinic on diseases of the female urethra.

CARSEY HOSPITAL.

Tuesday, October 24.

F. W. Johnson and L. E. Phaneuf—9. Gynecological operations. L. E. Phaneuf—2. Gynecological clinic.

Wednesday, October 25.

J. T. Bottomley, D. F. Mahoney, and A. McK. Fraser—9. General surgical operations. C. M. Proctor—2. Oral surgery. W. E. Browne—2. End-results and demonstration of traumatic hands.

Thursday, October 26.

W. R. MacAusland and A. R. MacAusland—9. Orthopedic operations. W. R. MacAusland and A. R. MacAusland—2. Orthopedic demonstrations.

Friday, October 27.

J. T. Bottomley, D. F. Mahoney, and A. McK. Fraser—9. General surgical operations. D. J. Hurley and T. J. Shanahan—2. Eye, nose and throat operations.

PETER BENT BRIGHAM HOSPITAL.

Tuesday, October 24.

Harvey Cushing, W. C. Quinby, David Cheever, John Homans, and E. C. Cutler—9. General surgical operations. David Cheever, John Homans, E. C. Cutler, and F. C. Newton—2. Clinical demonstrations and talks (general surgical cases).

Wednesday, October 25.

Harvey Cushing, W. C. Quinby, David Cheever, John Homans, and E. C. Cutler—9. General surgical operations. Harvey Cushing, Gilbert Horrax, and Percival Bailey—2. Clinical demonstrations in neurological surgery.

Thursday, October 26.

Harvey Cushing, W. C. Quinby, David Cheever, John Homans, and E. C. Cutler—9. General surgical operations. W. C. Quinby, Roger Graves, and J. J. Jackson—2. Clinical demonstrations in genito-urinary surgery.

Friday, October 27.

Harvey Cushing, W. C. Quinby, David Cheever, John Homans, and E. C. Cutler—9. General surgical operations.

ST. ELIZABETH'S HOSPITAL.

Tuesday, October 24.

Arthur Chute—9. Genito-urinary operations. Arthur Crosbie—9. Genito-urinary operations.

Wednesday, October 25.

Joseph Stanton and Henry Rowen—9. General surgical operations. George Keenan and Francis Jantzen—9. General surgical operations.

Thursday, October 26.

Joseph Stanton and Henry Rowen—9. General surgical operations. George Keenan and Francis Jantzen—9. General surgical operations.

Friday, October 27.

Thomas Broderick—9. Orthopedic operations. Charles Kickham—9. Gynecological operations and obstetrical ward visit.

BOSTON LYING-IN HOSPITAL.

Tuesday, October 24.

R. S. Eustis—2. Hemorrhagic disease of the newborn. Donald Munro—2. Intracranial hemorrhage in the newborn.

Wednesday, October 25.

F. S. Newell—2. Caesarean section under local anesthesia. F. C. Irving—2. Abdominal abortion with sterilization. B. E. Hamilton—2. Cardiac complications of pregnancy.

Thursday, October 26.

F. S. Newell—9. Caesarean section.

BOSTON DISPENSARY.

Tuesday, October 24.

John D. Adams and associates—9. Orthopedic operations: Hibbs operation, tuberculosis of spine; claw foot; rigid flat-foot.

Staff Clinic in Out-Patient Department—9. H. F. Day and associates—General surgical cases. Maynard Ladd and associates—Pediatrics. Malcolm Storer and associates—Gynecology. W. E. Cheney and H. J. Inglis—Nose and throat clinic. John D. Adams and associates—Orthopedic clinic. T. C. Hill and F. P. Williams—Diseases of the rectum. A. H. Crosbie and associates—Genito-urinary cases. H. F. Perry and associates—Diseases of the skin. J. D. Adams and associates—2. End-results, tuberculosis of spine, claw foot; non-operative treatment of acute hip infection. Occupational therapy (with lantern slides).

Wednesday, October 25.

H. F. Day and associates—9. Surgical operations: Inguinal hernia in the child; ingrowing toe nail; septic hand, an industrial injury. F. P. Williams, T. C. Hill, and associates—9. Fissure in ano; internal hemorrhoids.

Staff Clinic in Out-Patient Department—9. H. F. Day and associates—General surgery. Maynard Ladd and associates—Pediatrics. Malcolm Storer and associates—Gynecology. W. E. Cheney and H. J. Inglis—Nose and throat clinic. John D. Adams and associates—Orthopedics. T. C. Hill and F. P. Williams—Diseases of the rectum. A. H. Crosbie and associates—Genito-urinary clinic. H. F. Perry and associates—Diseases of the skin.

Staff Clinic and Short Talks—2. Benjamin Tenney—Some points in the anatomy and surgery of the knee joint. W. P. Cones—Bone Syphilis. R. H. Gelpatriek—Ankylosis of the jaw. W. F. Temple—Out patient anesthesia. F. G. Barnum—Osteomyelitis. T. C. Hill

—Out-patient treatment of rectal diseases. Oliver G. Tinkham—Fracture of the elbow joint. Carl Bearse—Adaptation of amputation stumps to artificial limbs. J. J. Lynch, Jr.—Cervical adenitis. John J. Murphy—Abdominal diagnosis in the out-patient department. H. F. Day—Peritonitis following tonsillar infection.

Thursday, October 26.

W. E. Cheney and H. J. Inglis—9. Nose and throat operations. H. J. Inglis—9. X-ray diagnosis of diseases of nasal sinuses.

Staff Clinic in Out-Patient Department—9. H. F. Day and associates—General surgery. Maynard Ladd and associates—Pediatrics. Malcolm Storer and associates—Gynecology. W. E. Cheney and H. J. Inglis—Nose and throat clinic. T. C. Hill and F. L. Williams—Diseases of the rectum. A. H. Crosbie and associates—Genito-urinary clinic. H. F. Perry and associates—Diseases of the skin.

Clinic by Staff—2. W. E. Preble—Post-operative care of patients. Herman Osgood—X-ray treatment. A. K. Paine—Treatment of gonorrhea in women. L. H. Spooner—Health clinic. Maynard Ladd and Hilbert F. Day—Pyloric stenosis in infants; medical and surgical aspects.

Friday, October 27.

Staff Clinic in Out-Patient Department—9. H. F. Day and associates—General surgery. Maynard Ladd and associates—Pediatrics. Malcolm Storer and associates—Gynecology. W. E. Cheney and H. J. Inglis—Nose and throat. J. D. Adams and associates—Orthopedic clinic. T. C. Hill and F. L. Williams—Diseases of the rectum. A. H. Crosbie and associates—Genito-urinary clinic. H. F. Perry and associates—Diseases of the skin. H. F. Perry and associates—2. Accidents and complications in treatment of syphilis; bone syphilis; epithelioma of the skin and its treatment by radium; carbon dioxide snow as a therapeutic agent.

LONG ISLAND HOSPITAL.

Wednesday, October 25.

John H. Cunningham and associates—9:30. Genito-urinary operations. John H. Cunningham and associates—2. Demonstration of genito-urinary cases.

Friday, October 27.

John H. Cunningham and associates—9:30. General surgical operations.

MASSACHUSETTS CHARITABLE EYE AND EAR INFIRMARY.

Tuesday, October 24.

E. A. Crockett and associates—9. Ear operations. D. Crosby Greene, H. A. Barnes and associates—9. Nose and throat operations. G. S. Derby—9. Eye operations; ward visit; out-patient clinic. F. H. Verhoef—9. Lantern slide demonstration of pathological specimens.

Wednesday, October 25.

D. H. Walker and assistants—9. Ear operations. F. E. Garland and assistants—9. Nose and throat operations. W. B. Lancaster, G. H. Ryder, and G. S. Derby—9. Eye operations; clinical demonstrations; ward visit; out-patient clinic. A. F. MacMillan—2. Demonstration of X rays at mastoids and accessory sinuses. H. P. Cahill—2. Demonstration of normal histological and pathological sections, especially of the internal ear. Staff—2. Demonstration of clinical cases.

Thursday, October 26.

W. F. Knowles and assistants—9. Ear operations. C. B. Faunce, Jr.—9. Nose and throat operations. F. H. Verhoef and S. J. McDonald—9. Eye operations; ward visit; out-patient clinic. H. P. Mosher, H. A. Barnes, and D. C. Greene—2. Demonstrations: End-results of tear sac operations; end-results of operation in cases of malignant disease of the accessory sinuses; a talk on the use of radium; end-results of cancer of the larynx. L. E. White—2. End-results of operations on the sphenoidal sinus. F. E. Garland and V. H. Kazanjian—2. End-results in cases of nasal deformity. H. P. Mosher, D. C. Greene, and D. C. Smith—2. Foreign bodies in the bronchus.

Friday, October 27.

Philip Hammond and assistants—9. Ear operations. H. P. Mosher and assistants—9. Throat operations. F. H. Verhoef and W. B. Lancaster—9. Eye operations; ward visits; out-patient clinic. E. A. Crockett—2. Demonstration of cases showing end-results of brain abscess and meningitis. Philip Hammond, H. P. Mosher, and D. C. Smith—2. End-results in cases of radical mastoid operations. G. L. Tober—2. End-results of operation for sinus thrombosis.

NEW ENGLAND DEACONESS HOSPITAL.

Tuesday, October 24.

D. F. Jones—9. General surgical operations. D. F. Jones—2. Carcinoma of the rectum. L. S. McKittick—2. Radium treatment of carcinoma of the rectum.

Wednesday, October 25.

F. H. Lahey—9. Thyroid and general surgical operations. Elliot P. Joslin—2. Treatment of diabetes and its surgical complications.

Thursday, October 26.

F. H. Lahey—9. Thyroid and general surgical operations. F. H. Lahey—2. Clinic on thyroid disease. B. E. Hamilton—2. Cardiac complications of thyroid disease and diagnosis of thyroid disease. H. M. Clute—2. Postoperative care and complications of thyroid disease. L. F. Sise—2. Anesthesia in thyroid disease. Sarah M. Jordan—2. Basal metabolism.

Friday, October 27.

F. H. Lahey—9. Thyroid and general surgical operations. F. H. Lahey—2. Clinic on thyroid disease. B. E. Hamilton—2. Cardiac complications of thyroid disease and diagnosis of thyroid disease. H. M. Clute—2. Postoperative care and complications of thyroid disease. L. F. Sise—2. Anesthesia in thyroid disease. Sarah M. Jordan—2. Basal metabolism.

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN.

Tuesday, October 24.

Isabel D. Kerr and Margaret L. Noyes—9. Nose and throat operations. Blanche L. Atwood, Olga Leary, and Mabel D. Ordway—9. Unusual case of glandular enlargement with marked hypertrophy of the breasts and mental symptoms.

Wednesday, October 25.

Elizabeth T. Gray and Florence Duckering—9. Gynecological operations. Marion Nute, Evelyn Lyle, and B. McW. Ryder—9. Obstetrical operations. Mabel D. Ordway—2. Neurosyphilis. Blanche Denig and Dr. Wright—2. Medical cases.

Thursday, October 26.

Leticia D. Adams—9. General surgical operations. Isabel D. Kerr—9. Nose and throat operations. Staff—2. Obstetrical, prenatal, and post-natal cases.

FORSYTH DENTAL INFIRMARY.

Tuesday, October 24.

Percy R. Howe—9. Short talks on recent dental research. Elmer W. Barron and Herman Robbins—9. Pediatrics as applied to dentistry.

Wednesday, October 25.

William E. Cheney, E. E. Tilton, W. G. Tunnel, A. A. Barrow, B. F. Murray and Louis Arkin—9. Adenoid and tonsil operations. Louis Arkin—9. Adenoid and tonsil operations. M. J. Eisenberg—9. Dental Orthopedics.

Thursday, October 26.

W. A. Gobie—9. Extracting. Percy R. Howe and Ruth E. Hatch—9. Dental research laboratory demonstration. Mary G. Jackson—9. Dental prophylaxis.

Friday, October 27.

F. M. Erlenbach—9. Dental clinic. Leroy M. S. Miner—9. Oral surgery. E. W. Barron and H. S. Robbins—9. Nutrition, pediatric clinic.

BETH ISRAEL HOSPITAL.

Wednesday, October 25.

Albert Ehrenfried and Carl Bearse—9. General surgical operations. Albert Ehrenfried—2. Hereditary deforming chondrodysplasia and certain allied growth distortions (with lantern slides). S. A. Robins—2. A consideration of the diagnostic points in the interpretation of abdominal X-rays.

Thursday, October 26.

E. G. Crabtree—9. Genito-urinary operations.

Friday, October 27.

Wyman Whittemore and Maurice Barron—9. General surgical operations.

CAMBRIDGE HOSPITAL.

Tuesday, October 24.

J. W. Sever—9. Orthopedic operations. A. H. Crosbie—2. Genito-urinary operations.

Wednesday, October 25.

Albert August, E. A. Darling, A. W. Dudley, H. P. Stevens, and associates—9. General surgical operations. N. S. Bacon and E. J. Butler—2. Demonstration of nose and throat cases.

Thursday, October 26.

N. S. Bacon and E. J. Butler—9. Nose and throat operations. J. L. Huntington—2. Prenatal clinic. F. B. M. Cady—2. Neurological clinic.

Friday, October 27.

Albert August, E. A. Darling, A. W. Dudley, H. P. Stevens, and associates—9. General surgical operations.

COLLIS P. HUNTINGTON MEMORIAL HOSPITAL.

Wednesday, October 25.

Clinic by Staff—2. R. B. Greenough—The cancer problem. William Duane—Short wave length x-ray

therapy. Homer Wright—Free diagnosis service. William Boyie—New contributions of physics to biology. Channing Simmons—Radium in cancer of buccal mucosa and tongue. D. Crosby Greene—Radium in carcinoma of jaw and larynx. George Minot—Radium in Hodgkin's disease. G. G. Smith—Radium in cancer of the bladder. G. A. Leland—Radium in carcinoma of cervix. Ernest Daland—Radium in skin lesions, malignant and benign. Leland S. McKittrick—Radium in cancer of rectum.

Friday, October 27.

Clinic by Staff—2. R. B. Greenough—The cancer problem. William Duane—Short wave length x-ray therapy. Homer Wright—Free diagnosis service. William Boyie—New contributions of physics to biology. Channing Simmons—Radium in cancer of buccal mucosa and tongue. D. Crosby Greene—Radium in carcinoma of jaw and larynx. George Minot—Radium in Hodgkin's disease. G. G. Smith—Radium in cancer of the bladder. G. A. Leland—Radium in carcinoma of the cervix. Ernest Daland—Radium in skin lesions, malignant and benign. Leland S. McKittrick—Radium in cancer of rectum.

EVANGELINE BOOTH HOSPITAL.

Tuesday, October 24.

A. K. Paine—9. Prenatal clinic.

Thursday, October 26.

A. K. Paine and Stephen Rushmore—9. Gynecological operations.

Friday, October 27.

A. K. Paine and Stephen Rushmore—9. Gynecological operations.

UNITED STATES NAVAL HOSPITAL.

Tuesday, October 24.

Lieut. J. W. White—9. Orthopedic operations: Keller operation for hallux valgus; arthrotony of knee for internal derangement; osteotomy for mal-united humerus; repair of finger tendon.

Wednesday, October 25.

Commander J. J. Woodward—9. General surgical operations.

Thursday, October 26.

Lieut. D. A. Heffernan—9. Eye, ear, nose, and throat operations. Various manifestations of syphilis from an ophthalmological standpoint; enucleations of tonsils; nasal septum corrections. Demonstration of aural cases of acute nasal sinusitis requiring operation.

Lieut. J. W. White—2. Hallux valgus treated by the Keller operation, end-results and X-rays. Recurrent dislocation of the shoulder treated by the Charnier-Ehrlich operation, end-results. Finger tendon repair, end-results. Malunion of femora treated by osteotomy, end-results. Generalized osteitis fibrosa treated by conservative means, end-results. Two cord injuries; one a persistent spastic hemiplegia, the other a complete recovery after a Brown-Séquard syndrome at the level of the sixth dorsal vertebra.

THE PROPER USE OF THE HYPODERMIC SYRINGE.

PETER BENT BRIGHAM HOSPITAL.
Oct. 10, 1922.

Mr. Editor:

Apropos of the editorial on the "Lawful Possession of Hypodermic Syringes," in the BOSTON MEDICAL AND SURGICAL JOURNAL for September 21, 1922, it is quite evident that the Massachusetts law, there cited, works an injury to ill citizens of the Commonwealth. In the editorial a glandular product is cited as an example. Two such come at once to mind, pituitrin and adrenalin chloride. Pituitrin is the only known means of controlling diabetes insipidus, and in most cases must be given subcutaneously daily or twice daily. Adrenalin is more important. It often is the only means of controlling attacks of asthma. It is effective only if given subcutaneously. Asthma is a disease commonly met with. Often adrenalin must be used repeatedly. Frequently the asthmatic develops a severe paroxysm in the small hours of the night. Is it fair to him to so regulate matters by law that he must either have a nurse constantly on call or send for a physician, perhaps suffering prolonged discomfort because he must await while the physician dresses and travels to the patient? This is unnecessary expense to the poor, and needless discomfort to the rich, unless a nurse is taken out of general serviceableness to be on hand to give the hypodermic of adrenalin when needed. (This, too, is undesirable in the community.) This law should be modified to permit of a physician not only prescribing drugs which require hypodermic injection, but also prescribing the syringe with which the patient takes the prescribed medicine. We know that use of hypodermic syringes by patients under these and similar conditions is safe, sane and desirable.

Very truly yours,

HENRY R. CHRISTIAN.

NOTICES.

THE JOINT MEETING OF THE PLYMOUTH, BRISTOL NORTH, BRISTOL SOUTH, AND HARNSTABLE DISTRICTS.

By invitation of Dr. Sumner Coolidge, this meeting will be held Nov. 9 at the Lakeville Sanatorium, Middleboro. Those who attended last year were graciously entertained, and those who could not be present missed an enjoyable and profitable meeting. The program will be published later.

BOSTON SURGICAL SOCIETY, INC.

A special meeting of the Society will be held at Jordan Hall, Huntington Avenue and Gainsborough Street, on Wednesday evening, October 25, 1922. Dr. William Williams Keen, Emeritus Professor of Surgery, Jefferson Medical College, Philadelphia, will give an address entitled "Sixty Years of Surgery: 1862-1922." On this occasion will be made the second award of the Henry Jacob Bigelow medal.

WALTER C. HOWE, Secretary.

ROBERT W. LOVELL, President.

A joint meeting of the Worcester District and the Worcester North District Medical Societies will be held at Burbank Hospital, Fitchburg, Tuesday, October 31, 1922, at 4.30 p.m. sharp. State officers will speak on subjects of importance. Dr. John Bryant of Boston will read the paper of the day. Subject: "Hospital Convalescents." Buffet lunch. L. F. Baker, President. C. H. Jennings, Secretary.

SOCIETY MEETINGS.

DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District:—Ilyannia,—November 3, 1922, February 2, 1923, (Annual Meeting)—May 4, 1923.

Bristol South District:—Fall River,—November 2, 1922, May 3, 1923.

Essex North District:—Haverhill, (Semi-Annual Meeting)—Jan. 3, 1923, Y. M. O. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Hampden Districts:—With Hampshire District in Holyoke. Regular meeting in October.

Suffolk District:—Combined meeting of Boston Medical Library and Suffolk District, November 22, 1922; December 27, 1922; January 31, 1923; February 28, 1923; March 25, 1923; Annual Meeting, April 25, 1923.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Hist. The date for each speaker has not been assigned.

Middlesex North District:—Meetings Wednesday, October 25, 1922; Wednesday, January 31, 1923.

Worcester District meetings in Worcester, Nov. 8, Dec. 13, 1922, Jan. 10, Feb. 14, March 14, April 11 and May 9, 1923, the last named date being the annual meeting.

A joint meeting of the Worcester and Worcester North Districts will be held at the Burbank Hospital, Fitchburg, Oct. 31, 1922.

A joint meeting of the Plymouth, Bristol North, Bristol South and Barnstable Districts will be held at Lakeville Sanatorium, Middleboro, on November 9, 1922.

STATE, INTER-STATE AND NATIONAL SOCIETIES.

The American Association of Oral and Plastic Surgeons will hold their annual meeting at the Medical Library, Boston, on October 20th and 21st.

Clinical Congress of the American College of Surgeons will be held in Boston, Mass., on October 23-27, 1922, Franklin H. Martin, Chicago, Director-General.

Massachusetts Association of Boards of Health, October 26, 1922, Worcester, Mass., W. H. Allen, Mansfield, Mass., Secretary.

New York and New England Association Railway Surgeons, 32nd Annual Meeting at New York City, October 25, 1922, Donald Guthrie, Sayre, Pa., Secretary.

November, 1922. Massachusetts Society of Examining Physicians, (Date and place of meeting undecided), Hilbert F. Day, Secretary. National Cancer Week, November 12 to 18.

December, 1922. New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3.30 p.m., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

January, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston, W. H. Allen, Mansfield, Mass., Secretary.

February, 1923. New England Dermatological Society Meeting, February 14, 1923, at 3.30 p.m., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

March, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary.

April, 1923. New England Dermatological Society Meeting, April 11, 1923, at 3.30 p.m., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston, W. H. Allen, Mansfield, Mass., Secretary.

May, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided). American Pediatric Society Meeting, May 31, June 1 and 2, 1923, at French Lick Springs Hotel, French Lick, Ind., H. C. Carpenter, Secretary.

June, 1923. American Medical Association, San Francisco, June 25-29, 1923, Alexander R. Craig, Chicago, Ill., Secretary.

July, 1923. Massachusetts Association of Boards of Health, July 26, Nantasket, W. H. Allen, Mansfield, Mass., Secretary.

*Deceased Sept. 2, 1922.

The Boston Surgical Society.

INTRODUCTION OF DR. W. W. KEEN.

By ROBERT W. LOVETT, M.D.,

President of the Boston Surgical Society.

At the Special Meeting of the Society, in Boston, on October 25, 1922, for the Presentation of the Henry J. Bigelow Medal to Dr. Keen.

The accomplished surgeon, wherever he lives and whatever his surroundings, must needs be a man of more than average ability. He must possess a sound knowledge of the science of medicine and, in addition

to this, he must be familiar with and adept in the handicraft of surgery. If he is to attain national or even international repute it is obvious that he must be endowed with characteristics and powers of a grade far above the ordinary allotment.

These characteristics are of two kinds, professional and personal. His professional attainments may be in general or special surgery, and in these he may reach eminence in one or more of several directions. He may be a successful and highly accomplished operator with a sound knowledge of the principles of general surgery which lie at the root of all practical surgical performance; or he may be a man, who by research can add to our surgical knowledge and thus to our efficiency in saving life and preserving function. He may be a distinguished teacher who possesses the faculty of stimulating the student and imparting to him a real knowledge of the principles and practice of surgery by teaching him to think instead of teaching him to remember. He may be a sound and clear writer who can assemble existing facts and add new ones from his experience in such a way as to raise the level of surgical knowledge and thus add to the efficiency of the profession. He may possess such rare qualities that he excels in more than one of these departments. So much for his professional qualifications.

With professional qualifications alone a man may go far in any of the lines mentioned, but if to these he adds personal qualifications of a certain sort he becomes a man of eminence and distinction. The required personal qualifications are possessed by nearly all really successful surgeons to a greater or less degree. They are cleanliness of mind and body, straightforwardness and honesty, squareness and unselfishness. If in addition to these he possesses fearlessness, vision and idealism, he becomes a man to whom we all turn and whose example and advice we follow.

Such a man has been invited by the Boston Surgical Society to address us this evening.

Address.

SIXTY YEARS OF SURGERY.*

1862—1922.

BY W. W. KEEN, M.D.,

Emeritus Professor of Surgery,
Jefferson Medical College, Philadelphia, Pa

Henry J. Bigelow I admired at a distance as a superior being, as was becoming in a student and young teacher. The older I grew and the more I knew, the more I admired him. Little did I dream, when I first opened Gray's "Anatomy" and Gross' "Surgery"—both quite new books in 1860—that I should ever have my name linked with those of Gray and Gross, and now, by your unexpected kindness, also with that of Bigelow. I thank you most sincerely for this great and unexpected honor.

While turning over in my mind several possible topics for this address, one of my eminent but younger surgical friends remarked that he knew only vaguely the condition of surgery at the time of the Civil War. This at once gave me my topic.

I began my medical studies in September, 1860, and graduated in March, 1862. Accordingly, I have selected as my subject—

"Sixty Years of Surgery
1862—1922."

As you shall see, I decline to be a champion of the Past—a *laudator temporis acti*. The rôle I assume is that of a Herald of the Dawn. This early dawn will surely brighten, in your day, into the full light of day. We hand you the torch of learning and bid you God speed. Take courage, you fine, younger fellows, my cherished colleagues in the profession. Free from the many handicaps of our preceding generation, you have the greater responsibility. But I am sure that you will more than measure up to it—that you will more than make good.

I shall rapidly sketch surgical conditions during the 60's and 70's; and our then means and methods of surgical diagnosis and treatment. It is only by such a contrast and in some detail that one can appreciate the poverty of our knowledge and the meagreness of our resources in the 60's and your wealth of both in 1922.

This statement suggests a speculation as to what your orator sixty years later may have to tell. I dare not make the attempt; the actuality would doubtless put my prognostications to shame. Would that I could return in 1982 and

converse with the Bigelows, the Grosses, the Mayos, the Flexners and the Lovetts of that wonderful day!

In the 50's and 60's, medical students were in an early developmental stage, a good deal beyond the "Old Stone Age," of course, but with some of its feral antagonisms still manifest.

The police and the medical students were far more intimately acquainted then than now. The professors, too, were frequently obliged to mediate between them. Rather often one of the Jefferson Faculty was hauled out of bed to haul a student in turn out of the lockup.

Their belligerency may be judged by a story told me by Dr. Weir Mitchell. It must have occurred shortly before 1860. A young man desired to enroll with him as an "office student." In questioning him as to his educational qualifications, Mitchell fortunately asked if he had any "accomplishments," whereupon he put his hand to the back of his neck, drew forth a bowie knife, and, without a word, implanted it deftly in the frame of Mitchell's window between two panes of glass. It is needless to add that he was referred to a more martial preceptor.

Indian wars were almost constantly in progress and arrow wounds, therefore, were not uncommon. The first case I ever personally cared for was a Regular Army Officer, a patient of my preceptor, Dr. John H. Brinton. An arrow had penetrated deeply just below the left eye. Severe secondary hemorrhage from the internal maxillary artery—a very rare accident—required ligation of the external carotid.

In 1876, when "Sitting Bull" was on the war-path, our German governess, ignorant of the curious Indian names, came to me in great perplexity. "Herr Doctor," she said, "I cannot understand what my German paper says about a 'Sitzende Ochse.'" When one thinks of it, a bull sitting on its haunches like a dog would be a rather odd farm phenomenon.

Physiology was in an elementary condition; Pathology hardly existed. Gross' "Pathological Anatomy" (1839) was the first American book on that subject. My course of lectures at the Jefferson on "Pathological Anatomy," chiefly surgical and only in the "Summer Course" in 1866-67, was the first course ever given in Philadelphia. Tyson's course in General Pathology at the University of Pennsylvania began in 1879. Harvard founded a Chair of Pathology in 1847, but Surgical Pathology was first taught unofficially by Warren in the late 60's. The first official course in Surgical Pathology was authorized in 1897. A laboratory was added as late as 1901. At Columbia (then the College of Physicians and Surgeons), the lectures on Pathology and Pathological Anatomy were instituted in 1888.

In 1865-66, I was a pupil in Virchow's Laboratory, with his little railroad on the long,

*An address on receiving the Henry Jacob Bigelow Gold Medal of the Boston Surgical Society, October 25, 1922.

continuous table winding to right and left, to propel his microscopes from student to student. A year later, in the Philadelphia School of Anatomy and the Jefferson, I used a microscope on a horizontal wooden base, with a vertical stage between the lens and a kerosene lamp. This was passed from hand to hand. *Per contra*, almost all of you are contemporaries of the epidiascope and the projectoscope.

Artists for medical drawing were scarce, and by reason thereof, and also of the *res angusta domi* of a young doctor, I made my own, copying them from Paget, Virchow, Billroth, etc. Even in our text books, crude wood-cuts were the best illustrations we knew. The splendid illustrations of to-day were far away. The "American Text Book of Surgery" (1892) was one of the earliest to utilize the new school of artists.

Spontaneous generation was then the battlefield. Just after the Civil War, in Paris I was a pupil of Pouchet fils, whose father was Pasteur's tenacious opponent, so that for the time, I was near the center of that long and bitter fight. Experiment after experiment seemed to prove the truth of spontaneous generation, but Pasteur always found the weak spot in the experiments of Pouchet and others, and dealt a death stroke. By the 70's, spontaneous generation was as dead as Julius Caesar.

Evolution and Darwin's "Origin of Species" (published in 1859, the year I graduated at Brown), had caused a volcanic explosion which gradually subsided save for sporadic eruptions. The reemergence of this fight fifty years later is a curious but surely only a passing phenomenon.

Clinical surgery was well established in 1860, but it was very crude and simple. We had two clinics each in Medicine and Surgery on Wednesdays and Saturdays. Whenever there was a capital operation to be performed, such as even an amputation of leg or breast, it was known beforehand and then we all rushed to get front seats, as described in that medical classic, "Rab and His Friends."

Thank God, in the 60's we had one great boon—Anesthesia! My elders have described to me the horrible ordeal an operation was for patient, surgeons and witnesses before 1846. The screams and struggles of the patient were heartrending. To add to the horror, the then means for checking hemorrhage were primitive and largely ineffectual. The operating room resembled a slaughter house.

Observe the influence of the "Death of Pain," as Weir Mitchell justly called the result of the introduction of anesthesia. In the five years (1841 to 1846) in the Massachusetts General Hospital, only 184 operations were done; that is, 37 in a whole year, or three a month. Now, in any large hospital a score every day excites no remark.

Boston is rightly proud of her preëminence in the introduction of anesthesia. October 16, 1846, is a red-letter day, not only in the Annals of Surgery, but in the Annals of Mankind.

In December, 1847, Sir James Y. Simpson, of Edinburgh, first used chloroform. For years those two were the only anesthetics. Only for a few years have we had instruments of precision to measure accurately the dose of these anesthetics.

In 1884, local anesthesia by cocaine was introduced by Koller. The number of the local anesthetics is now large, and the end is not yet.

In 1909-10,¹ Meltzer and Auer introduced Insufflation Anesthesia, a great improvement in special cases.

Nitrous oxid, a long-established anesthetic for such brief operations as drawing a tooth or opening an abscess, later was combined with oxygen, and, largely through the efforts of Crile, the further combination of these two with novocain, or other local anesthetic, has been a most important advance, greatly reducing shock and mortality.

In the 60's, assistants in the dissecting room often came directly to the surgical clinics to assist in the operations, soap and water being the only disjunctive conjunction, for we knew nothing of germs and germicides. The same revolving table was used for the cadaver in the lectures of the Professor of Anatomy, and for the surgical operations in the clinic. The surgeons—Pancoast, Gross and all the others—operated in discarded, blood-stained coats, the veterans of a hundred fights.

There were no ward classes. Students only looked on at operations. Had I not been a private "office student" with Brinton and DaCosta, I should never have palpated, ausculted or percussed a patient's heart, lungs or abdomen, never have looked through a microscope, even then an infrequent privilege. No medical college had a microscope for instruction.

The microscopes of that day were far behind those of to-day in mechanical construction. There were no oil immersion lenses, no dark field illumination, no ultra-microscope. The only stain was carmine, followed by acetic acid to clear the specimen. There were no compound stains.

The whole teaching Faculty consisted of seven Professors and one Demonstrator (Anatomy).

All the sacred seven courses began at once. Hence, in my first surgical lecture, I heard about blood corpuscles and capillaries which I had never seen, and the buffy coat, of which my only idea was that it could not be an article of apparel, but had something to do with the blood. Even now I would not covet a too minute examination as to the said buffy coat. Forgive

¹ Medical Record, N. Y., March 19, 1910, p. 411.

me if I suspect that you, too, might pass by only a narrow margin.

The first operation I ever saw was removal of an upper jaw by that prince of operators, Joseph Pancoast. It is always a rather bloody one. I had just swallowed my luncheon. By throwing out all my grappling hooks, I barely succeeded in holding it down.

At the Jefferson, we had two rooms, with five or six beds each, for the most serious cases, over a saloon conveniently adjoining the College. When Gross reached his lecture on Suppuration, he usually said to the orderly, "Hugh, go over to the hospital to-morrow morning and get me a half tumblerful of pus for my lecture." He might well have been less modest as to the amount, for "laudable pus" was "on tap."

Save the dissecting room, not one laboratory existed. Now at the Jefferson we have eighteen laboratories.

The very first Laboratory of Research in the United States was established in 1884 by Mr. Carnegie, in connection with the Bellevue Hospital Medical School. The Blue Cross has recently published a list of eighty-six such laboratories, all doing fine work for science, for animals, and for mankind.

As late as the 80's, and even into the 90's, there were, in most hospitals, no trained nurses. The nurses were chiefly women of very moderate intelligence who had gained experience by the rough method of "trial and error," and the "error" might easily have been in your own case or in that of one very dear to you. If so, your fervent prayers were sorely needed.

Hospitals were then avoided as if leprous, instead of being our best refuge. The wards were full of fear and not seldom of despair, instead of, as now, of hope and alert expectation of recovery.

Even the surgeons themselves were none too well trained. I well remember, at the First Bull Run, when I was but a First Lieutenant, and had not even graduated, but had already been well trained by Brinton in operative surgery, I was holding an arm for an amputation at the shoulder joint. The operator's assistant, a Major, was vigorously compressing the subclavian artery *below* the clavicle. I felt compelled, for a life was at stake, to intimate very modestly that possibly the pressure might be more effective *above* the clavicle. He turned upon me a withering face and voice and said, "The very name of the artery is *subclavian*," leaving me wilted but not convinced. When the operator divided the great blood-vessels in the armpit, a violent gush of blood followed, which I quickly arrested by seizing the severed vessels, as Brinton had taught me.

On another occasion during the Civil War as the surgeon I was assisting in an amputation of the thigh was about to sharpen the stump

like a lead pencil by cutting the flaps upward, I averted disaster by suggesting, very *solito voce*, the reverse direction for the flaps, and this time was thanked for it.

The only speculum we had in common use to examine any internal organ was that abomination, the tubular uterine speculum.

Many surgeons had handled kitchen spoons, but it required the "prepared mind" of Marion Sims in 1849 to transform such a spoon into a wonderful surgical aid by simply bending the handle. But it did not come into general use for some years. The bivalve speculum came still later.

Helmholtz had devised the ophthalmoscope in 1851; Czermak, the laryngoscope in 1860, but so slight an impression had the latter made that when I asked my preceptor Da Costa, in 1861, what he thought of the statement of Green of St. Louis that he actually could see the vocal chords, he replied in a doubtful tone that he "thought it might be true." But I never saw them myself until after the Civil War.

Similarly, the medical use of the thermometer was practically unknown. We judged of fever by placing the hand on the arm or neck. But we never estimated it in degrees, only in adjectives as "none," "slight," "considerable," "high" or "very high." I doubt if there were half a dozen thermometers in the Army of the Potomac. Mitchell, Morehouse and I had to import those we used in Turner's Lane Hospital in 1863-64.

The first book on Medical Thermometry was published by Wunderlich in 1868. The first short "Clinical Thermometer" (devised by Sir Clifford Allbutt in 1867) I ever saw, was brought to me from London in 1876 by Weir Mitchell.

Imagine the mother of half a dozen children to-day without a thermometer as a guide to whether the doctor should be called!

To-day we all recognize the scientific value of the thermometer, but we sometimes overlook its value to the doctor as a life preserver against the garrulous. In severe cases of loquacity, I have known a certified one minute thermometer to require even more than five minutes to reach its acme of accuracy!

Again, you are the contemporaries of Radium, which gives promise of great usefulness, and of the X-rays. You know the value of these rays in diagnosing fractures, foreign bodies in the heart, lungs, intestines, and the tissues, and in the diagnosis of cancer of the stomach and bowel, and the arrest of their contents by any obstruction. Now you can even see a sclerosed artery in its course down the arm. Cerebral Ventriculography was unknown until 1919.

Of the blood, our knowledge was most primitive. We knew its two kinds of corpuscles, but nothing of leucocytosis in its relation to inflammation, or of the four different categories

of blood. Blood was simply "bloo l." We knew nothing of the color index, nothing of blood pressure (save as inaccurately estimated by the pulse), and its great importance in operative surgery. The electro-cardiograph was not even a dream.

In 1866 I visited Marey's laboratory in Paris to learn how to use his lately devised Sphygmograph. He tested my own pulse and told me it was weak. But time has shown that what it has lacked in vigor it has made up in pertinacity.

We had no knowledge of test meals. The stomach tube was practically used only in cases of poisoning. To-day, Charles Mayo writes: "I should prefer to see a stomach tube rather than a stethoscope hanging around the neck of my surgical intern."

I have a vivid recollection as a lad of my reluctance to acknowledge that I felt "sick" until I *had* to, because it meant invariably the nausea following a horrid home emetic and then the bitter epsom salt or castor oil—ugh! One of the advantages of Gross' famous "Antimonial and Saline Mixture" was that the two enemies went down arm in arm at a gulp.

Practically *every* patient in the hospital wards was taking alcohol. One of the staff of the Pennsylvania Hospital recently told me that now only two patients in his present large service were getting any alcohol, and he was in some doubt of its wisdom even in these two.

Here I must stress the chief advance in scientific and practical surgery ever made—the development of Bacteriology and its application to surgery by the antiseptic method of Lister.

Vaccination (May 14, 1796), Anesthesia (October 16, 1946), and Antisepsis² are the three greatest blessings in the realm of medicine conferred on man since the Christian era began.

Pasteur's work was fundamental. Lister's genius applied Pasteur's discoveries to surgery. This wrought the greatest revolution surgery has ever witnessed. The Germ Theory of Disease is no longer a theory, but an abundantly proved *Fact*. Those who deny that the Tubercle bacillus, the Typhoid bacillus, the Diphtheria bacillus, and other germs, do not cause the diseases named, have minds that are simply impermeable to any arguments addressed to reason or common sense.

Originally, the antiseptic ritual was complicated, now it is very simple. At first, the germs in the atmosphere were believed to be our chief enemies. Now we know that they exist on every material object, and that death hides especially under the shelter of the surgeon's finger nails. They exist on the skin of doctor, nurse and patient, on instruments, dressings, ligatures, in unboiled water and other fluids, and are carried by many animals and insects. In fact, deadly

germs are ubiquitous. *Everything* needs to be disinfected before the operator, assistants or nurses dare touch it or allow it to touch a wounded surface. All of this knowledge has been achieved since 1867.

While I was writing this, a non-medical friend told me that the birth of one of his children occurred unavoidably in the country. When the doctor, a dear old man beloved by the whole community, arrived, the nurse offered him a basin of bichlorid solution for his hands. He declined it, saying, "No thank you! I don't need it. I washed my hands just before I hitched up my horse." "The date?" you ask. Nineteen hundred and three. You and I may smile at such ignorance, but, in all soberness, may not this explain some needless tragedies of maternity in 1923?

No one particular year can be assigned as the date of the introduction of Antisepsis. Pasteur's famous papers on Lactic Acid Fermentation and on Alcoholic Fermentation were read in August and December, 1857. Lister's first paper was published in 1867. Bacteriology and Antisepsis went hand in hand. They had to fight for their lives. Their chief opponents, I am sorry to say, were the ultra-conservative surgeons. False friends betrayed them. Argument assaulted them. Ridicule tried to discredit them, as when one well known and able surgeon declared that he "stood at a distance and cast septic glances at the patient."

But Bacteriology and the Antiseptic Method marched steadily onward and finally *won* all the world by the late 70's and early 80's, saving a few fossil doctors and the ignorant antivivisectionists. Asepsis was a natural development. The scientific basis of both Antisepsis and Asepsis is identical, the only difference is the means by which to attain the same end.

Until the 80's or 90's we had no vaccines against the various disease-producing germs. Smallpox was the only enemy we could combat by vaccination. Even today we do not know its cause. That is a problem for *you* to solve. We had no serums. We knew not how to prevent tetanus, diphtheria, malaria, yellow fever and other diseases, of which we have now the whiphand.

Surgical tuberculosis could not be definitely diagnosed in bones, joints, or in what we called "serofula," because we knew not the real cause of tuberculosis until 1882. Not knowing the cause we could not know that tuberculosis was contagious and was spread by spitting, coughing and in food. No protective measures for the well were even thought of. The consumptive was thought to be doomed (and in fact was doomed) from the moment the diagnosis was made.

In a word, we had no knowledge of Bacteria and Bacteriology. That science was fragmentary even down to 1884, by which time it had

² Under Antisepsis I mean, of course, to include Bacteriology. In reality, Antisepsis and also Sanitation are largely "Applied Bacteriology."

become systematized and first acquired its name.

We knew nothing of endocrine glands and their important functions—nothing of hormones and their mechanism.

Of course, we had no Schick test, Noguchi test, Pirquet test, Wassermann reaction, etc. We knew nothing of the spreading of diseases by the fly, the flea, the mosquito, the louse, the rat, the cattle tick—and hence we could not take any protective and preventive measures against them.

The whole human race and our animal friends were besieged before and behind, on the right and on the left. We were not only defenseless, we were not even aware that these enemies existed.

The only barrier which could be erected was a quarantine against those persons and goods which might carry infection. It was believed that clothing, bedding, etc., could carry the infection of yellow fever. Quarantine at first meant forty actual days (*quaranta*) of detention, often under disgusting and sometimes brutal conditions, sometimes with shot guns ready for any attempt at evasion, and it was useless as we now know.

Our then so-called sanitation was ineffective because our real enemies—the bacteria—were unknown. Now sanitation is our principal reliance because its sound basis is Bacteriology.

The operative surgery of my surgical youth consisted briefly of—

- (1) Amputations, most of which we can now avoid
- (2) Ligation of arteries, especially for aneurism and secondary hemorrhage
- (3) Occasional excision of joints—not seldom fatal
- (4) Removal of external tumors, such as cancer of the breast
- (5) Ovariectomy. But this was not done until the tumor was so large as to imperil life.⁵

Surgeons who removed ovarian tumors were persecuted. As a student, I even heard them called murderers in the Jefferson Clinic because "two out of three of their patients died." It ought to have been worded, "one out of every three recovered," for every recovery was a rescued life.

In 1846, Mütter, one of my predecessors in the Chair of Surgery, said, "It is certainly hazardous but little to assert that in a very few years ovariectomy will be assigned to the oblivion it so well merits." Now, thanks to McBowen, the Atles, Pasteur and Lister, and many others, the mortality is less than one in a hundred.

In 1876, in reviewing American Surgery for the preceding century, Professor Samuel D. Gross could only quote⁶ seven operations for goiter by Greene of Portland, Maine, of whom five recovered and two died, and Maury's two cases, of whom one died, a mortality of respectively thirty-five and fifty per cent.

Of 1834 cases of operation on all varieties of goiter in the Mayo clinic in 1919, only twelve died, or two-thirds of one per cent.

6. Cutting for stone in the bladder had long been done. The method of performing lithotomy, in my early surgical days, was a legacy from pre-anesthetic days when speed was essential on account of the horrible pain. It was like the "hundred yard dash." Surgical guests (for it was a "show" operation), as well as students, watch in hand, timed the operator. He who could triumphantly hold up the culprit stone in the grasp of his forceps in ten or fifteen seconds less than any rival, was by so much the better surgeon. When every moment was like an hour of agony, no wonder that such "slap dash surgery" was imperative. Even a tyro can see that all our finer, delicate, painstaking and artistic surgery was impossible when a patient, bound hand and foot and also held in the grip of several strong men, was unwillingly but unavoidably writhing with excruciating pain. Prolonged pain also exhausted the patient and was a serious addition to the probability of death.

In 1878, Bigelow introduced litholapaxy, *i.e.*, crushing of the stone and evacuation of the fragments, at one sitting,—an immense forward step.

7. In 1867, Bobbs of Indianapolis was the first surgeon who ever removed gallstones from the gall-bladder. Before that other similar sufferers were left to Mother Nature and she generally slew them in due season.

8. In my student days I often saw couching for cataract, *i.e.*, pushing the opaque lens down into the vitreous done by Pancoast and Levis, both general surgeons—how horrible that sounds to us to-day! The oncoming flags of Ophthalmology and the other several specialties were then just becoming visible above the distant horizon.

9. On the head, the chest and the abdomen was writ large, "Hands off!" And no wonder! Before the days of Lister, death from meningitis, from violent pleurisy or pneumonia, and from virulent peritonitis was almost always the result of any operation in these three cavities.

Even the cause of appendicitis—then called "perityphilitis," "local peritonitis" or "abscess in the right iliac fossa"—was not known till Fitz's epochal paper in 1886 revealed the appendix as the real criminal.

⁵As an instance of this delay, years ago I removed a huge ovarian tumor, which weighed 111 pounds, from a young girl not yet sixteen years of age. After the recovery she herself, that a what better for aught, weighed only 48 pounds. Dr. Freeman, my son-in-law, who I had him of this, lifted a warning finger and said, "I hope you, Father, been very careful or some day you will be the wrong piece."

⁶American Journal of the Medical Science, January, 1876, pp. 431-484.

10. One strange exception was trephining. Archeologists have found even prehistoric skulls with multiple trephine openings in the same skull, the margins of the openings in the bone from previous operations being soundly healed. Trephining in my early surgical days was practically limited to compound depressed fractures of the skull with a large mortality.

11. There was occasional plastic surgery, especially in the making of new noses from the skin of the forehead, but the frequent failures left the patient still without any nose and with the unwelcome acquisition of a most unsightly scar on his forehead.

12. Before 1895, Tracheotomy for diphtheria,⁵ then called "membranous croup," was a frequent tragedy. How often I have stood, knife in hand, awaiting the decision of the agonized parents. Not only they, but I, too, knew by an only too frequent dread experience, that grim death was awaiting his almost assured victim.

In 1895, the blessed antitoxin was discovered and, presto! as if by magic, tracheotomy for diphtheria became infrequent, and for years past, one may say, has been unknown! Never can I forget, when I was twelve years old, the death of a darling younger brother who was allowed to be choked to death before our eyes by this now almost vanquished monster.

13. Operations for the radical cure of quiescent hernia were rarely done. They were often a failure, and always a danger. When a hernia became strangulated, its reduction by manipulation was first tried, and was often repeated two or three times under ether. Even if ultimately apparently successfully reduced, we took the chance of a reduction *en masse* with still persisting strangulation, or of a possibly gangrenous condition of the bowel promoted by the repeated manipulation itself.

To intestinal obstruction proper, Gross' "Surgery" in 1859 gave only two-thirds of one page. He said, "Internal strangulation is generally a fatal disease, its very obscurity forbidding interference." Why did he not advocate opening the abdomen quickly, before great damage had been done, and dispel this "obscurity" by the light of day? Because Bacteriology was yet unborn, because Pasteur and Lister had not yet, by experimental research, made abdominal operations safe.

What, then, was the treatment Gross and Erichsen's contemporary text-books in 1860 suggested? Let me recount it to your astonished ears! Calomel and opium, leeches, fomentations which sometimes, they said, relieved "even the most hopeless and complicated cases." If not, then "after three or four days" one might operate. Today, thank God, sharp steel quickly lays bare the cause, and provides the life-saving procedures at once.

Our methods of performing these dozen operations were simple—and often fatal. Our hands were, as a rule, as clean as those of a gentleman, but were never disinfected. The patient's skin was similarly clean or cleansed, but not disinfected.

For preventing hemorrhage we had only the Spanish windlass and Petit's tourniquet—no Esmarch's bandage, and elastic tubes.

Our instruments, from germ-gathering, velvet-lined cases, were laid out on a table—and not disinfected. If they needed a little sharpening, I have—not often, but actually two or three times—seen them stropped on the boot, and even on its sole. If an instrument fell on the floor, it was swished in a basin of unsterilized water, and plunged into the wound without disinfection.

We had no artery forceps, hence, primary hemorrhage was profuse. It was arrested by seizing artery after artery separately by a tenaculum—a hook with a handle—and tied with undisinfected silk. One end was cut short, the other left long. All these long ends were gathered in one or two bundles, and left protruding from the wound. After amputation of a fleshy thigh, I have seen twenty or thirty of them. The two or three ligatures on the larger vessels were identified by a knot, the largest by two knots. After a few days, each non-knotted ligature was pulled upon to ascertain whether it had rotted—mark the word—rotted loose. No traction was made on the knotted ones for a week or more. When they came away, if a clot had formed, well and good. If not, then a furious secondary hemorrhage followed, and often required the reopening of the wound to tie the artery again, or its ligation by a new incision higher up, or even a re-amputation. Sometimes the patient died almost immediately. In 2235 cases of secondary hemorrhage during the Civil War, 61.7 per cent. died.

During one night, when "Officer of the Day" at the Satterlee Hospital, ten days after Gettysburg, I was called to treat five cases of secondary hemorrhage and, I am glad to say, saved five lives. This was a larger number of such cases than I have seen in all my thirty-odd years of later antiseptic practice.

In 1869, Lister introduced absorbable catgut ligatures. They gradually won their way into favor. Now, as you well know, we cut both ends short, and close the wound entirely. This is usually followed by immediate healing, and we never hear of the ligatures again.

We had no modern retractors; the hypodermic syringes, and the aspirator were not in general use. These came into common use toward the end of and after the Civil War. The systematic use of the hypodermic syringe at Turner's Lane Hospital by Mitchell, Morehouse and Keen was exceptional.

⁵ So called from the tough "leather" like membrane, which forms in the throat and extends into the windpipe.

Only marine sponges—round, flat, and “elephant-eared”—were used, both in clean and in suppurating cases! After using them in pus cases, we did wash them as thoroughly as possible, but knew not how to disinfect them. In fact, “disinfection” was a word unknown in the language of surgery in the 60’s. Gauze “sponges” came into general use, as nearly as I can remember, in the late 70’s or early 80’s.

How were our wounds dressed? Take an amputation as a sample. Simple cerate was spread on a square of patent lint or on any old linen sheet, shirt, etc., clean but undisinfected. Then, by cutting from the four corners part way towards the center, we made a sort of Maltese cross. This was applied “cup-wise,” one might say, to the stump, and covered with clean linen rags held in place by a recurrent bandage. This was pinned on, as we had no rubber plaster. The first “absorbent cotton” I ever saw I bought in 1876 at the Centennial Exposition. The amputation was redressed daily, and when “laudable pus” began to flow freely, twice or thrice daily.

On the second or third day the patient became restless and sleepless from pain and thirst, with a temperature, as I now judge, of $103\frac{4}{5}^{\circ}$. In a week to ten days, when free supuration set in, the fever fell to probably $100-101^{\circ}$, the appetite would improve somewhat, and sleep would be bettered; hence, the adjective “laudable.”

If all went well, the wound would be healed in four, five or six weeks. But very often all did not go well. Secondary hemorrhage, erysipelas, gangrene, blood poisoning would develop, and then the patient who escaped with life, after two, three or four months, was fortunate. The many ligatures, until they sloughed away, caused constant supuration, with constant danger of blood-poisoning. The mortality was dreadful, as compared with our present almost certain recovery.

My happy, younger surgical colleagues, you cannot imagine the Paradise you have been born into, compared with the Purgatory in which we lived for so many years.

In dislocations of the hip, and sometimes of the shoulder, the barbarous block and pulley were used. They could apply great force. In the old Jefferson amphitheater there were heavy hooks opposite each other for using this apparatus. The patient was anesthetized and laid on the floor. A strong perineal band, to hold the patient in place, was fastened to one hook, and the pulley to the other. By stout linen bandages or a broad leather band, the pulley was then fastened to the leg or arm, and then tremendous force was applied till it seemed as if the leg or arm would be literally torn away from the trunk. What a blessed relief your own may find now say our own. Bigelow (1869), and

later Kocher and others brought to these unfortunate patients by using gentle manipulative methods based on anatomical and surgical studies and experiments, in hip and shoulder dislocations!

More than once, too, in Paris, I saw tumors removed by Chassaignac’s “Eraseur.” A strong wire or linked steel chain encircled the base of the tumor, and passed through a small opening. Gradually, by the handle, the wire or chain was screwed tighter and tighter until it mechanically crushed its way through the tissues. You may thank God you never saw such diabolérie.

Fractures of the base of the skull were almost uniformly fatal, because we had no means of disinfecting the epharynx. Indeed, we did not even know that such disinfection was either needful or possible!

Look up what Gross and Erichsen, in 1859, say about “Mastoid Disease.” You will look long and look in vain.

Sir William Macewen of Glasgow, the protagonist of cerebral surgery, and happily still living and working, has given an authoritative chronology of its beginning in his presidential address before the British Medical Association on July 25, 1922.⁷

His opening words, “In my student days physiologists taught us that the brain acted as a whole,” vividly recall to my mind the notable symposium on Cerebral Localization, in Washington at the First Congress of American Physicians and Surgeons in 1888. Among the speakers were Charles K. Mills, Roswell Park, Allen Starr, Robert F. Weir, Dr. (now Sir) David Ferrier and Mr. (later Sir) Victor Horsley, both of London, and myself.

I then compared the head with the abdomen, each containing a number of viscera, wholly separate physically in the abdomen, but in the head physically fused into one mass—the brain—but separable physiologically and pathologically. This is today commonplace, but then was a novelty.

In 1867, Hughlings Jackson had foreshadowed cerebral localization. In 1870, Fritsch and Hitzig had applied electricity to the brain of dogs. In 1883, Ferrier had emphasized the idea of cerebral localization of functions, and had urged surgical interference in proper cases. The *Lancet* (Nov. 10, 1883), in a long two-page editorial, rejected this proposal, and closed with these words: “If Dr. Ferrier’s suggestions meet with much practical response, it is to be feared that cerebral localization will soon have more deaths to answer for than lives to boast of.”

Yet Macewen, in his address, states that, in 1879 a cerebral tumor had already been diag-

⁷ B. M. 1731, 1732, 1733, 1734, 1735, 1736, 1737, 1738, 1739, 1740, 1741, 1742, 1743, 1744, 1745, 1746, 1747, 1748, 1749, 1750, 1751, 1752, 1753, 1754, 1755, 1756, 1757, 1758, 1759, 1760, 1761, 1762, 1763, 1764, 1765, 1766, 1767, 1768, 1769, 1770, 1771, 1772, 1773, 1774, 1775, 1776, 1777, 1778, 1779, 1780, 1781, 1782, 1783, 1784, 1785, 1786, 1787, 1788, 1789, 1790, 1791, 1792, 1793, 1794, 1795, 1796, 1797, 1798, 1799, 1800, 1801, 1802, 1803, 1804, 1805, 1806, 1807, 1808, 1809, 1810, 1811, 1812, 1813, 1814, 1815, 1816, 1817, 1818, 1819, 1820, 1821, 1822, 1823, 1824, 1825, 1826, 1827, 1828, 1829, 1830, 1831, 1832, 1833, 1834, 1835, 1836, 1837, 1838, 1839, 1840, 1841, 1842, 1843, 1844, 1845, 1846, 1847, 1848, 1849, 1850, 1851, 1852, 1853, 1854, 1855, 1856, 1857, 1858, 1859, 1860, 1861, 1862, 1863, 1864, 1865, 1866, 1867, 1868, 1869, 1870, 1871, 1872, 1873, 1874, 1875, 1876, 1877, 1878, 1879, 1880, 1881, 1882, 1883, 1884, 1885, 1886, 1887, 1888, 1889, 1890, 1891, 1892, 1893, 1894, 1895, 1896, 1897, 1898, 1899, 1900, 1901, 1902, 1903, 1904, 1905, 1906, 1907, 1908, 1909, 1910, 1911, 1912, 1913, 1914, 1915, 1916, 1917, 1918, 1919, 1920, 1921, 1922, 1923, 1924, 1925, 1926, 1927, 1928, 1929, 1930, 1931, 1932, 1933, 1934, 1935, 1936, 1937, 1938, 1939, 1940, 1941, 1942, 1943, 1944, 1945, 1946, 1947, 1948, 1949, 1950, 1951, 1952, 1953, 1954, 1955, 1956, 1957, 1958, 1959, 1960, 1961, 1962, 1963, 1964, 1965, 1966, 1967, 1968, 1969, 1970, 1971, 1972, 1973, 1974, 1975, 1976, 1977, 1978, 1979, 1980, 1981, 1982, 1983, 1984, 1985, 1986, 1987, 1988, 1989, 1990, 1991, 1992, 1993, 1994, 1995, 1996, 1997, 1998, 1999, 2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010, 2011, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019, 2020, 2021, 2022, 2023, 2024, 2025, 2026, 2027, 2028, 2029, 2030, 2031, 2032, 2033, 2034, 2035, 2036, 2037, 2038, 2039, 2040, 2041, 2042, 2043, 2044, 2045, 2046, 2047, 2048, 2049, 2050, 2051, 2052, 2053, 2054, 2055, 2056, 2057, 2058, 2059, 2060, 2061, 2062, 2063, 2064, 2065, 2066, 2067, 2068, 2069, 2070, 2071, 2072, 2073, 2074, 2075, 2076, 2077, 2078, 2079, 2080, 2081, 2082, 2083, 2084, 2085, 2086, 2087, 2088, 2089, 2090, 2091, 2092, 2093, 2094, 2095, 2096, 2097, 2098, 2099, 2100, 2101, 2102, 2103, 2104, 2105, 2106, 2107, 2108, 2109, 2110, 2111, 2112, 2113, 2114, 2115, 2116, 2117, 2118, 2119, 2120, 2121, 2122, 2123, 2124, 2125, 2126, 2127, 2128, 2129, 2130, 2131, 2132, 2133, 2134, 2135, 2136, 2137, 2138, 2139, 2140, 2141, 2142, 2143, 2144, 2145, 2146, 2147, 2148, 2149, 2150, 2151, 2152, 2153, 2154, 2155, 2156, 2157, 2158, 2159, 2160, 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2172, 2173, 2174, 2175, 2176, 2177, 2178, 2179, 2180, 2181, 2182, 2183, 2184, 2185, 2186, 2187, 2188, 2189, 2190, 2191, 2192, 2193, 2194, 2195, 2196, 2197, 2198, 2199, 2200, 2201, 2202, 2203, 2204, 2205, 2206, 2207, 2208, 2209, 2210, 2211, 2212, 2213, 2214, 2215, 2216, 2217, 2218, 2219, 2220, 2221, 2222, 2223, 2224, 2225, 2226, 2227, 2228, 2229, 2230, 2231, 2232, 2233, 2234, 2235, 2236, 2237, 2238, 2239, 2240, 2241, 2242, 2243, 2244, 2245, 2246, 2247, 2248, 2249, 2250, 2251, 2252, 2253, 2254, 2255, 2256, 2257, 2258, 2259, 2260, 2261, 2262, 2263, 2264, 2265, 2266, 2267, 2268, 2269, 2270, 2271, 2272, 2273, 2274, 2275, 2276, 2277, 2278, 2279, 2280, 2281, 2282, 2283, 2284, 2285, 2286, 2287, 2288, 2289, 2290, 2291, 2292, 2293, 2294, 2295, 2296, 2297, 2298, 2299, 2300, 2301, 2302, 2303, 2304, 2305, 2306, 2307, 2308, 2309, 2310, 2311, 2312, 2313, 2314, 2315, 2316, 2317, 2318, 2319, 2320, 2321, 2322, 2323, 2324, 2325, 2326, 2327, 2328, 2329, 2330, 2331, 2332, 2333, 2334, 2335, 2336, 2337, 2338, 2339, 2340, 2341, 2342, 2343, 2344, 2345, 2346, 2347, 2348, 2349, 2350, 2351, 2352, 2353, 2354, 2355, 2356, 2357, 2358, 2359, 2360, 2361, 2362, 2363, 2364, 2365, 2366, 2367, 2368, 2369, 2370, 2371, 2372, 2373, 2374, 2375, 2376, 2377, 2378, 2379, 2380, 2381, 2382, 2383, 2384, 2385, 2386, 2387, 2388, 2389, 2390, 2391, 2392, 2393, 2394, 2395, 2396, 2397, 2398, 2399, 2400, 2401, 2402, 2403, 2404, 2405, 2406, 2407, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417, 2418, 2419, 2420, 2421, 2422, 2423, 2424, 2425, 2426, 2427, 2428, 2429, 2430, 2431, 2432, 2433, 2434, 2435, 2436, 2437, 2438, 2439, 2440, 2441, 2442, 2443, 2444, 2445, 2446, 2447, 2448, 2449, 2450, 2451, 2452, 2453, 2454, 2455, 2456, 2457, 2458, 2459, 2460, 2461, 2462, 2463, 2464, 2465, 2466, 2467, 2468, 2469, 2470, 2471, 2472, 2473, 2474, 2475, 2476, 2477, 2478, 2479, 2480, 2481, 2482, 2483, 2484, 2485, 2486, 2487, 2488, 2489, 2490, 2491, 2492, 2493, 2494, 2495, 2496, 2497, 2498, 2499, 2500, 2501, 2502, 2503, 2504, 2505, 2506, 2507, 2508, 2509, 2510, 2511, 2512, 2513, 2514, 2515, 2516, 2517, 2518, 2519, 2520, 2521, 2522, 2523, 2524, 2525, 2526, 2527, 2528, 2529, 2530, 2531, 2532, 2533, 2534, 2535, 2536, 2537, 2538, 2539, 2540, 2541, 2542, 2543, 2544, 2545, 2546, 2547, 2548, 2549, 2550, 2551, 2552, 2553, 2554, 2555, 2556, 2557, 2558, 2559, 2560, 2561, 2562, 2563, 2564, 2565, 2566, 2567, 2568, 2569, 2570, 2571, 2572, 2573, 2574, 2575, 2576, 2577, 2578, 2579, 2580, 2581, 2582, 2583, 2584, 2585, 2586, 2587, 2588, 2589, 2590, 2591, 2592, 2593, 2594, 2595, 2596, 2597, 2598, 2599, 2600, 2601, 2602, 2603, 2604, 2605, 2606, 2607, 2608, 2609, 2610, 2611, 2612, 2613, 2614, 2615, 2616, 2617, 2618, 2619, 2620, 2621, 2622, 2623, 2624, 2625, 2626, 2627, 2628, 2629, 2630, 2631, 2632, 2633, 2634, 2635, 2636, 2637, 2638, 2639, 2640, 2641, 2642, 2643, 2644, 2645, 2646, 2647, 2648, 2649, 2650, 2651, 2652, 2653, 2654, 2655, 2656, 2657, 2658, 2659, 2660, 2661, 2662, 2663, 2664, 2665, 2666, 2667, 2668, 2669, 2670, 2671, 2672, 2673, 2674, 2675, 2676, 2677, 2678, 2679, 2680, 2681, 2682, 2683, 2684, 2685, 2686, 2687, 2688, 2689, 2690, 2691, 2692, 2693, 2694, 2695, 2696, 2697, 2698, 2699, 2700, 2701, 2702, 2703, 2704, 2705, 2706, 2707, 2708, 2709, 2710, 2711, 2712, 2713, 2714, 2715, 2716, 2717, 2718, 2719, 2720, 2721, 2722, 2723, 2724, 2725, 2726, 2727, 2728, 2729, 2730, 2731, 2732, 2733, 2734, 2735, 2736, 2737, 2738, 2739, 2740, 2741, 2742, 2743, 2744, 2745, 2746, 2747, 2748, 2749, 2750, 2751, 2752, 2753, 2754, 2755, 2756, 2757, 2758, 2759, 2760, 2761, 2762, 2763, 2764, 2765, 2766, 2767, 2768, 2769, 2770, 2771, 2772, 2773, 2774, 2775, 2776, 2777, 2778, 2779, 2780, 2781, 2782, 2783, 2784, 2785, 2786, 2787, 2788, 2789, 2790, 2791, 2792, 2793, 2794, 2795, 2796, 2797, 2798, 2799, 2800, 2801, 2802, 2803, 2804, 2805, 2806, 2807, 2808, 2809, 2810, 2811, 2812, 2813, 2814, 2815, 2816, 2817, 2818, 2819, 2820, 2821, 2822, 2823, 2824, 2825, 2826, 2827, 2828, 2829, 2830, 2831, 2832, 2833, 2834, 2835, 2836, 2837, 2838, 2839, 2840, 2841, 2842, 2843, 2844, 2845, 2846, 2847, 2848, 2849, 2850, 2851, 2852, 2853, 2854, 2855, 2856, 2857, 2858, 2859, 2860, 2861, 2862, 2863, 2864, 2865, 2866, 2867, 2868, 2869, 2870, 2871, 2872, 2873, 2874, 2875, 2876, 2877, 2878, 2879, 2880, 2881, 2882, 2883, 2884, 2885, 2886, 2887, 2888, 2889, 2890, 2891, 2892, 2893, 2894, 2895, 2896, 2897, 2898, 2899, 2900, 2901, 2902, 2903, 2904, 2905, 2906, 2907, 2908, 2909, 2910, 2911, 2912, 2913, 2914, 2915, 2916, 2917, 2918, 2919, 2920, 2921, 2922, 2923, 2924, 2925, 2926, 2927, 2928, 2929, 2930, 2931, 2932, 2933, 2934, 2935, 2936, 2937, 2938, 2939, 2940, 2941, 2942, 2943, 2944, 2945, 2946, 2947, 2948, 2949, 2950, 2951, 2952, 2953, 2954, 2955, 2956, 2957, 2958, 2959, 2960, 2961, 2962, 2963, 2964, 2965, 2966, 2967, 2968, 2969, 2970, 2971, 2972, 2973, 2974, 2975, 2976, 2977, 2978, 2979, 2980, 2981, 2982, 2983, 2984, 2985, 2986, 2987, 2988, 2989, 2990, 2991, 2992, 2993, 2994, 2995, 2996, 2997, 2998, 2999, 3000, 3001, 3002, 3003, 3004, 3005, 3006, 3007, 3008, 3009, 3010, 3011, 3012, 3013, 3014, 3015, 3016, 3017, 3018, 3019, 3020, 3021, 3022, 3023, 3024, 3025, 3026, 3027, 3028, 3029, 3030, 3031, 3032, 3033, 3034, 3035, 3036, 3037, 3038, 3039, 3040, 3041, 3042, 3043, 3044, 3045, 3046, 3047, 3048, 3049, 3050, 3051, 3052, 3053, 3054, 3055, 3056, 3057, 3058, 3059, 3060, 3061, 3062, 3063, 3064, 3065, 3066, 3067, 3068, 3069, 3070, 3071, 3072, 3073, 3074, 3075, 3076, 3077, 3078, 3079, 3080, 3081, 3082, 3083, 3084, 3085, 3086, 3087, 3088, 3089, 3090, 3091, 3092, 3093, 3094, 3095, 3096, 3097, 3098, 3099, 3100, 3101, 3102, 3103, 3104, 3105, 3106, 3107, 3108, 3109, 3110, 3111, 3112, 3113, 3114, 3115, 3116, 3117, 3118, 3119, 3120, 3121, 3122, 3123, 3124, 3125, 3126, 3127, 3128, 3129, 3130, 3131, 3132, 3133, 3134, 3135, 3136, 3137, 3138, 3139, 3140, 3141, 3142, 3143, 3144, 3145, 3146, 3147, 3148, 3149, 3150, 3151, 3152, 3153, 3154, 3155, 3156, 3157, 3158, 3159, 3160, 3161, 3162, 3163, 3164, 3165, 3166, 3167, 3168, 3169, 3170, 3171, 3172, 3173, 3174, 3175, 3176, 3177, 3178, 3179, 3180, 3181, 3182, 3183, 3184, 3185, 3186, 3187, 3188, 3189, 3190, 3191, 3192, 3193, 3194, 3195, 3196, 3197, 3198, 3199, 3200, 3201, 3202, 3203, 3204, 3205, 3206, 3207, 3208, 3209, 3210, 3211, 3212, 3213, 3214, 3215, 3216, 3217, 3218, 3219, 3220, 3221, 3222, 3223, 3224, 3225, 3226, 3227, 3228, 3229, 3230, 3231, 3232, 3233, 3234, 3235, 3236, 3237, 3238, 3239, 3240

nosed by this means, and successfully removed by operation, and several others also had been operated on up to 1883. Apparently, this was not generally known. Horsley's paper on the Topography of the Cerebral Convulsions⁹ was to me a revelation as novel and illuminating as the mapping of Central Africa by Livingstone and Stanley. All of these motor centers have been determined by experiments on animals, confirmed later by clinical and pathological data in man.

I embodied the contents and the illustrations of Horsley's paper in my edition of Gray's "Anatomy" (1887). Also, at the Congress in 1888, I presented the three specimens, and the three patients constituting my first three cases of modern cerebral surgery, all diagnosed absolutely by cerebral localization. My very first case was that of a large tumor, removed in December, 1887. This patient lived until 1917, thirty years after operation. During all of that long period he had lived with no roof to his left lateral ventricle save the scalp.

To name even a partial list of our own colleagues who have contributed to the development of cerebral surgery is impossible for want of time. But all of us will gladly pay tribute to the eminent services of your distinguished townsman Harvey Cushing.

In 1888, Gowers' and Horsley's paper¹⁰ describing the first localization and subsequent removal of a tumor of the spinal cord, was a momentous forward step.

The institution of drainage for empyema in 1854, by Henry I. Bowditch, your own distinguished townsman, was a wonderful boon. The modern, open treatment of surgical affections of the lungs and pleura, needed the Great War to develop its greatest usefulness.

Chevalier Jackson—who has created and developed a wholly new department in Surgery, removal of foreign bodies in the air passages and the esophagus through the mouth—was not born till 1865. Tracheotomy for such foreign bodies disappeared when Jackson waved his magic wand. Foreign bodies, such as coins, etc., if swallowed, it was hoped, would pass, and if they did not, rarely indeed was any surgeon bold enough to remove them by operation in that day of infection and death.

Even in gunshot, stab, and other similar wounds, in which the three forbidden cavities were already opened, we operated reluctantly, and with a timidity justified by the lethal results.

So far in this rapid review, I have told you what we *dared* not do and *could* not do in the past. Let me now swiftly recount by glorious contrast some of the things that we now *can* do, what in fact are *almost a daily routine* in every great hospital.

After a single battle in the Russian campaign,

Farrey, Napoleon's great surgeon, performed not less than 200 amputations. Today, of 200 similar cases, sometimes even with wounds involving joints—a great additional danger—we can conserve the majority of these useful limbs without amputation.

External tumors of any size are now removed from all parts of the body without fear of a frequently fatal erysipelas, which a century ago so worried Sir Astley Cooper before he operated on the King for a simple wen.

The mere fact that any tumor is internal—inside the head, chest, abdomen or pelvis—has little influence on the decision whether it should be removed or not.

In the head, the new surgery trephines without hesitation, for trephining *per se* now involves very slight danger. Tumors of the brain are removed, abscesses opened, the ventricles are punctured with impunity or distended with air for diagnostic purposes. Foreign bodies are removed and the Gasserian ganglion, and even the hypophysis and the pineal gland are no longer beyond the surgeon's reach. Spinal tumors are now exactly located, and are constantly removed.¹¹

I have already given you the data for goiter and tracheotomy for diphtheria.

In the chest, that very citadel of life, the heart lies in a straight line only one inch from the surface, yet, as Frederic Lee has strikingly said, it took surgery, with laggard step, twenty-four centuries to travel that one inch. Now, the heart is sutured for stab and gunshot wounds, with a recovery of over 50 per cent. Foreign bodies, revealed by the uncanny x-rays, have been removed even from its interior.

As I am writing this, Allen and Graham¹² have shown that in dogs it is possible to make a small opening into the cavity of the left auricle of the heart, insert a small tube with a lens at the further end, illuminated by an electric lamp, and study—not in less than three minutes, as heretofore, but at some leisure—the condition of the mitral valve, and, by a delicate knife, operate upon the valve itself. The mortality in the dogs, of course, has been high, but certainly will be greatly lessened with a larger experience. I fully expect that in time this method may be made safe enough to be applied to man himself. And yet there are those who wish to prevent such a beneficent research!

The esophagus is attacked for cancer, large portions of the chest wall are excised, foreign bodies removed, and the lungs can now be operated on at leisure, thanks to insufflation anesthesia!

The stomach is opened with impunity for the extraction of foreign bodies; portions of its walls are removed for cancer, and for ulcers,

to prevent these latter from developing into cancers; even the entire stomach has been removed, and at least temporary recovery has followed. Early operations may hereafter enable us to say permanent recovery has been achieved.

As to the intestines, we have yet to find any condition or injury which prohibits our interference, and nearly always with success, unless the disease has gone too far, and the injury is too extensive. We open the bowel to remove foreign bodies which, if they have escaped us in the esophagus and the stomach, become our prey in the bowel. We remove even many feet of the bowel, and, unless the removal is too extensive, without any appreciable effect on the political economy of the abdomen. When we have abstracted a part, we unite the two open ends of the bowel, and thus re-establish the continuity of the alimentary canal. Of this, happily, after even eleven years, I am, myself, a surviving, grateful witness.

We short-circuit the intestinal contents. We remove the appendix almost "while you wait." If done early, its mortality is negligible. If the appendix is healthy, we can utilize it as a means for irrigating an inflamed colon.

Hernia is now a curable condition, with no appreciable mortality. Strangulated hernia and intestinal obstruction, if quickly operated on, have now only a small mortality.

We remove tumors of the liver, and successfully treat wounds of its substance. Gallstones and even the entire gall-bladder are removed every day or two. In one case I removed 301 gallstones. That last one I was particularly glad to find, and record as a proof of meticulous truthfulness.

The spleen is anchored, sutured, or even removed at will. We wonder why there should be any appendix, gall-bladder or spleen, for the patients seem to get along quite as well without them as with them. Possibly they persist by the forgetfulness of some animal ancestor; and incidentally, for the benefit of us surgeons.

The pancreas is no longer inaccessible; the kidney is sutured in place, drawn outside the body for inspection, decapsulation, or incision if, as the x-ray will have informed us, there are stones in its interior. A portion of the diseased kidney can be removed, or even one entire kidney, if hopelessly damaged by disease or accident. Stones in the ureter are also readily removed.

In the pelvis, the bladder is opened to remove stones or for tumors, and may be partially or wholly removed, in which case the ureters are made to débouche into the bowel. Removal of the prostate is almost an everyday operation, for which the aged patients are most grateful for their relief in most cases from intolerable suffering. The uterus, ovaries, and the parovaria have a long list of life-saving, comfortable and operations to their credit.

Was I not right when, years ago, I called the abdomen "the surgeons' playground"?

Listen again to Charles Mayo, in 1922: "In many years of active surgical work I have not seen death occur as a result of an unnecessary [abdominal] exploration . . . but many have died solely because exploration was done too late."

We suture and anastomose nerves or divide their roots, even within the spinal canal. We suture blood-vessels, even in the new-born, in case of life-threatening hemorrhage. We criss-cross arteries and veins to prevent gangrene, and Matas' endo-aneurismorrhaphy has saved many a limb.

We successfully transplant skin, bones, joints, and even half-joints—a much more difficult procedure.

We are gradually throttling disease at its very birth, and *preventing* its onslaught upon the health of the world.

I end as I began. As a representative of the passing, and at my age I may say the past generation, with uplifted hand I thank Almighty God for the wonderful progress He has enabled our generation to achieve. I crave for you, my younger brothers, His abundant blessing. To you may it be vouchsafed to win still greater victories for Humanity.

New England Hospital Association.

ANNUAL MEETING WEDNESDAY, MAY
17, 1922, AT BOSTON MEDICAL
LIBRARY.

(Continued from page 555.)

AFTERNOON SESSION.

Meeting called to order at two o'clock, by Dr. Howland.

DR. HOWLAND: The first business is the report of the auditing committee,—Mr. Lee.

MR. LEE: I wish to state that the committee has examined the books of the treasurer and has found them correct, and as stated in his report, and has endorsed them as correct as of May 17th.

DR. HOWLAND: You have heard the report of the auditing committee; what is your pleasure?

It was moved and seconded, and *Voted*, that the report of the treasurer be accepted.

DR. HOWLAND: The next business is the paper on "The Hospital as an Educational Factor in a Community," by Dr. Brown.

THE HOSPITAL AS AN EDUCATIONAL FACTOR IN A COMMUNITY.

By DR. THOMAS S. BROWN, Supt. of Mary Fletcher Hospital, Burlington, Vermont.

I desire to say at the beginning that I lay no claim to being the originator of all the ideas advanced in this paper; very many of them in fact I have acquired from others, but as they seem reasonable I should like to pass them on for your consideration. I am especially indebted for these ideas to Drs. Louis Jermain and H. C. Burdette.

The practice of medicine or physie, from which latter term is derived the word "physician," is as old as the human race; and is supposed from legendary accounts to have had its origin among the Chaldeans, Assyrians and Babylonians, the oldest known peoples of the earth.

The science of medicine, however, received its first real impetus in Egypt, where the opening of bodies after death to ascertain the cause of death was tolerated, and as early as 1100 B.C. there is said to have been a college of physicians in Egypt. Not only men, but women also became practitioners, so that we need not be at all disturbed at the increase of women physicians in this day.

Pliny, the historian, says that certain of the doctors were paid officers of the State, and were required to treat the poor free. They were not, however, required to go to the patients' homes, hence it is supposed that in Egypt, as in Athens at a later time, there were certain houses to which the poor came, something after the order of our dispensaries. These physicians were allowed to take fees from private patients even when in the employ of the State,—from this it would seem that State medicine may not become an immediate danger, since it has threatened so long. There has been considerable discussion in our section as to the proper relation of the public health official and the general practitioner and just how far the former should "hand out" his services without charge to the general public.

In the third century B. C. the king of India commanded that hospitals for the sick be established throughout the kingdom, and this was done by the nobles and landowners. Here patients from all lands were given free treatment. Many such hospitals were established in the fourth century and were described by a Chinese traveler in India.

By the first of the present century only one of these hospitals was still in existence and that was devoted to the care of animals instead of humans. This hospital covered an area of about twenty-five acres, and people of all castes could bring their aged animals here for care; and so much were these animals revered that bread and milk was furnished for them when they became too old to crop grass.

Among the first isolation hospitals were those established for the segregation of people suffering from leprosy. Such a "House of Separation," as it was called, was connected with a large hospital built by St. Basil at Caesarea.

This would seem to be the first attempt at preventive medicine, as the isolation was no doubt due more to the desire to protect the well than to care for the sick.

The ancient cities of Mexico had hospitals that were well endowed and attended by experienced physicians, according to Prescott's History of Mexico; and one writer stated that they were not only better than those of Europe, but that "they did not protract the cure in order to increase the pay." All of which goes to show that there are no new tricks even in the practice of medicine.

Of the early hospitals in modern countries we find that Hotel Dieu was founded in Paris in 600 A.D. St. Bartholomew's in London in 1123 A.D., or about that time. The hospitals in Germany came a little later, while in the United States the Pennsylvania Hospital is probably the oldest.

Until recent years hospitals have had as their sole object the care of the sick, and the restraint of the insane. It is only very recently that hospitals in this country have realized how large a part they should take in the education of the healthy; and that their obligation to humanity does not end with their treatment of the sick. However, some hospitals find it very difficult to meet this obligation; in fact, do meet it only partially and rather indifferently.

The true and full service which hospitals may and should render to the public has been very aptly set forth in a paper by Dr. Louis Jermain, Dean of Marquette University Medical School, entitled "The Educational Function of Hospitals." The ideas there set forth are relatively new in this country, although they were in a large part advocated by Henry C. Burdette, formerly Secretary and General Superintendent of Queens Hospital in Birmingham, England, and Registrar of the Medical School, in his extensive work on "Hospitals and Asylums of the World," which was published in 1893. Many, yes, most of the features which seem to be desirable and possible in a hospital were in operation in England at that time, which is about thirty years ago, and have since been seized upon by our American medical educational reformers. It would seem as if the ideas and reforms designed for the betterment of medical education in America were borrowed from a practice well established in England thirty years ago. Nevertheless the aim seems good, so we may perhaps review it with profit.

Dr. Jermain says: "All hospitals in cities where there is a medical school owe it to themselves and to the public to seek some touching connection with such school. Hospital authorities should hold themselves responsible in a large measure for the training of the future practitioners of medicine, and the members of the staffs of hospitals." Granted that this statement is true and that such a relation does

exist, what is the field open to a hospital as an educational factor in a community?

For convenience let us take it up under these heads:

First—Education of medical students.

Second—Education of staff and medical profession.

Third—Education of nurses.

Fourth—Education of internes.

Fifth—Education of the public.

Education of Medical Students.

It is rather interesting to note that in 1893, according to Dr. Burdette, there were in this country only a very few medical colleges which had anything but the very loosest connection with hospitals. The University of Pennsylvania had its own hospital; Johns Hopkins also had its hospital as part of the medical department of the college; but Harvard had not as yet any direct connection with the hospitals of Boston. Many of the medical schools were giving only a two-year course; some three, and a few a course of four years. Yet at that time English medical students were receiving their training on the wards of English hospitals. In the last few years the training of students by bedside observation has become a general practice in this country, and all thinking people appreciate that it is of great benefit to the medical student in the third and fourth years of his course to come in actual contact with patients. He then has an opportunity to observe the theory which has been given to him by didactic lectures put to the practical test. Truly the clinic and bedside study of patients is the "laboratory test" which makes real the statements of teachers which would otherwise be dry and meaningless.

What then are the advantages to the student? 1st, it trains him to meet patients with tact; to be gracious, and to secure the confidence of the patients. 2nd: By history taking, he is taught to ascertain from the patient's own story all that may bear on the case. 3rd: It trains him to observe carefully, thus adding his own opinions to the facts brought out by the history. 4th: It teaches him not to jump at conclusions, but to delay making a diagnosis in obscure cases until all the known tests have been used either to corroborate or to contradict his impressions. 5th: It gives him a chance to familiarize himself with the technique of many of these tests by actually doing them or by securing the material for someone else to do the work, when the process is too complicated for him to do it personally. 6th: It gives him a chance to observe the results of certain lines of treatment which are under the direction of the most competent doctors connected with the institution. This includes the treatment of medical cases and the pre- and post-operative treatment of surgical cases.

What are the advantages or disadvantages to the hospital and patients of having the stu-

dents on the wards? At first sight it would appear to be only a source of annoyance to the patients, and a nuisance to the hospital. But Burdette, commenting on hospital conditions in England, says, "The condition of residence in a hospital must always be strange at the outset to all patients. At first the presence of students may even be felt to be embarrassing, but this feeling soon wears off and is replaced by quite an opposite one, for by their kindness and skill students quickly win the confidence of the patients and their presence is a great element of brightness on the ward, and does very much to relieve the ennui and loneliness which might otherwise be felt. It is well known that patients are delighted, not grieved, when they find that their case is one of special interest to the students and one on which frequent demonstrations are made. Of course discretion is constantly called for that repeated examination is not harmful, but this discretion is rarely, if ever, wanting.

Dr. Osler says, "The work of an institution in which there is no teaching is rarely first class. It is, I think, safe to say, that in a hospital with students on the wards the patients are more carefully looked after, their diseases more fully studied and fewer mistakes are made.

Dr. Jernain says, "Medical students in a hospital are in a measure a guarantee of thorough work on the part of the staff and internes." May I add, if the staff and internes do their part. In a meeting of this sort I realize that there are many hospitals represented which do not have an opportunity to admit students to their wards, and I want to say that I believe this is a decided misfortune, for there can be no doubt that the student is a good stimulant to the members of the staff.

Education of Staff and Medical Profession.

If the hospital is a good place to begin the education of a doctor, or, perhaps, to educate the beginning doctor, it certainly is a place to *continue* the education of the doctor who is already at work. Plato tells us, "Education is a life-long process." No one will deny that the doctor who ceases to study and keep in touch with the rapid progress of medical science might better change his business. The hospital affords a place where the doctor can not only study his own cases but he is constantly rubbing elbows with other physicians. He learns what they are doing and is stimulated by this contact. Here he is able to make use of all the latest methods of diagnosis which the rush of his own private practice would not give him time to utilize even if he were thoroughly familiar with the technique. But best of all, and most serviceable to the doctor, is his contact with the students. He must at all times be at his best. Incompetency and bluff are quickly detected and sharply criticised by the students. Again Dr. Osler says, "There is not the keen

interest nor the thorough study of cases, nor, amid exigencies of the busy life is the hospital physician able to escape clinical slovenliness, unless he teaches and in turn is taught by internes and students."

But it is not to the students and internes alone that the doctor with hospital facilities can disseminate the benefits of his training. The man from a distance, who sends his patients to the hospital for treatment, frequently gains some new ideas on his visit to the hospital if the staff man does his duty and explains how he arrived at his diagnosis and what the nature of the treatment is. Every man's duty is to the public at large, and the more widely a man's influence is felt the greater the benefits.

The Education of Nurses.

So essential has the trained nurse become to the physician in order to accomplish the best results in every case and to secure any results at all in some cases, that it is impossible to comprehend what would be the state of affairs in the world without trained nurses.

And yet it is only since hospitals have taken such a prominent place in the care of the sick that it has been possible to train women for this useful service to humanity,—certainly nurses could not be trained without hospitals, nor could hospitals be run without nurses. The life of the nurse is one of the most arduous, and as a recompense she should receive the best of instruction; this she can receive to perfection only from the staff doctors. And it is her right to expect and demand her full measure of instruction as well as a liberal amount of criticism. The latter is always administered without stint, but altogether too frequently the doctor finds no time to carefully explain the why and wherefore of doing or not doing certain things. It is only by such a constructive procedure that a nurse can be given a well-rounded training. Many nurses are good imitators, and the result is a copy of some older nurse whose knowledge is often far from sufficient or satisfactory. It is the duty of the doctor to see that nurses receive intelligent criticism, which means patient and painstaking explanation of the way they like things to be done; if the way they have been done has not been satisfactory. All of this the nurse is entitled to in addition to the best of instruction from the training school teachers, but I am not in favor of making the educational requirements so high that every nurse would be trained for positions of responsibility, for though there is great need of efficient and responsible heads, we must not forget that what the patient needs is care and not a boss.

If the training of a nurse is what it should be it will prove a liberal education to her and make her not only a good nurse, but a useful citizen and the highest type of home-maker.

Education of the Interns.

The additional training and perfecting influence of the hospital has been so fully recognized that at the present time many medical colleges and some State boards are requiring a fifth year to be spent by the student as an interne in an approved hospital or in other acceptable clinical work before the degree of M.D. is granted.

While a student, a man is so crowded with new impressions and is so rushed from one thing to another that he has little time to digest what he hears and sees. But when he becomes an interne he perfects his laboratory technique; he learns care in diagnosis; he analyzes treatment; he learns to read people; he acquires a confidence in himself; he is invaluable to the hospital staff. Many a man who is an indifferent book and theory student becomes a cheerful and consistent worker when he is placed in charge of a ward of patients. The interne should have the benefit of association with the best of the profession; and if the hospital is a teaching hospital he has this association. The interne is the future guardian of the public health and every possible advantage should be given him to acquire skill and confidence. The average medical graduate is a man with a smattering of medical knowledge which he is unqualified to use. The hospital is a finishing room which turns a valuable raw product into a real public asset.

The Education of the Public.

How is this last and most important branch of hospital education to be accomplished? It is indeed a difficult task to make the public understand that by its service to the student, the staff, the nurse, and the interne, it is in reality serving the community. How many people state that "they won't be pawed over by students," little realizing that this "pawing over" is really the true and only scientific basis on which a diagnosis can or should be made. Only by a thorough and exhaustive examination can the real facts of a case be brought out, and the sooner the public learns that the student and the interne must be trained in the hospital or else go into practice untrained, the better. Without this the public would be in the hands of young and inexperienced physicians who would not have had the benefit of carrying out treatment under the direction of thoroughly competent older physicians.

It is altogether probable that few people die of mis-treatment at inexperienced hands; but it is also certain that some patients are constantly suffering from the effects of inefficient treatment due to a physician's lack of study sufficiently exhaustive to make an accurate diagnosis and to carry out the best treatment in each case.

We are still resorting too much to the old custom of treating symptoms. The public must learn that diseases are not properly studied

when we look simply at the patient's tongue; count his pulse and listen to his story.

We must therefore teach them that a careful examination may require several days; that the more men engaged in the study of the case the greater the probability that the real cause of the trouble will be ascertained and that students and internes take nothing for granted; consequently they are the best of assurances of thorough investigation. They must be taught that the staff doctor who is being watched and questioned by students and internes is much more eager and persistent in securing results than the man who is joggling along at his own pace. We must teach the people that the hospital is not a place of last resort, and to be avoided as the very entrance to Hades, but a place where early treatment produces the best results; that it is not a place where the impossible can be accomplished, but where certain advantages by way of diagnosis and treatment can be carried out more completely and successfully than at home; that the hospital is not a place where experiments in medicine and surgery are tried out regardless of the welfare of the patient. They should be made to understand that the well-being of the patient is always the first consideration and that the next is the study of all patients in order that the increase in medical knowledge may become a public asset available to all whether rich or poor.

The patient who refuses to have his case studied thoroughly is doing just so much to hinder the progress of medical science and is withholding from humanity just so much of benefit.

Thus far in this discussion we have proceeded as if all hospitals had a teaching connection with some medical college and were large enough to have internes and a nurses' training school. This of course is not true. There are very many hospitals which have no connection with any medical school, others which have no internes, and there are some which are not large enough to maintain a satisfactory training school. All of these things are a serious handicap. With the advent and recognition of the small community hospital now being advocated by the Rockefeller Foundation the number of hospitals with a limited service is constantly increasing. The directors and staffs of such hospitals should realize the tremendous responsibility resting upon them to maintain high standards of treatment. The hospital should furnish every possible advantage in the way of equipment and then require of the staff an unusual amount of devotion and considerable attention to details which is not required of the staffs of larger hospitals if they are to keep the hospital service from falling to a low grade. Unless carefully managed, these small hospitals will afford a place for men of very mediocre ability to impose their services upon the public. The welfare of the patient is the thing of primary

importance. It must never for any reason whatsoever be replaced by any other interest.

The medical profession stands ready to give unstinted service; with the coöperation of the public every hospital should not only give good treatment (this is the least that it can do), but should also, to the full measure of its opportunities, contribute to the public welfare a well-planned program of education.

DR. HOWLAND: Dr. Brown's very interesting paper is open for discussion. Dr. Washburn of the Massachusetts General Hospital has thought of a good many ways of utilizing a hospital besides caring for the sick. Will you not open the discussion, Dr. Washburn?

DR. WASHBURN: Mr. Chairman, Ladies and Gentlemen:

One way occurs to me in which the hospital can be of great service to the community, and that is by furnishing an opportunity for the education of the physicians of the community who are not on the hospital staff. For a good many years—if I may be excused for speaking of my own hospital—certain devoted men on the staff of the Massachusetts General have given weekly clinics for the doctors in the community. Dr. Smith and Dr. Cabot, in conjunction with the pathologist of the hospital, Dr. Oscar Richardson, have given these clinics once a week, and the busy practitioners of the towns round about have given their afternoons to come in and get brushed up a bit in medicine, and the methods of the study of clinical records in conjunction with autopsy findings. That has, not only the value of keeping the physicians round about with their medicine brushed up a little and up to time, but has the advantage to the hospital of creating a friendly atmosphere with the medical profession. That is one way in which we try to keep in touch with physicians. Another way is to try to keep the doctor who sends in the patient informed as to the progress of that patient. We try to let him know when the operation is coming, and urge him to be present, and we let him know when the patient is discharged, what the findings are, and we try to send the patient back to him.

The matter of education in the hospital itself with pupils who come to the hospital goes a good deal further, or should go, certainly in a large hospital, a good deal further than the training of the doctor and the training of the nurse. For instance, dietitians can well be educated in hospitals. We have our trained dietitians and graduates who are paid by the hospitals, and in many larger hospitals we have pupil dietitians, who get practical training in the hospital in conjunction with a course at some college.

The training of hospital superintendents is one of the most important branches of hospital education. He comes in just like Topsy; he just

grows. In the past, the hospital directors, as they are coming to be called now, the hospital superintendents, have got their training by being assistants to older men in charge of superintendents, until gradually they got their own hospitals, which was a pretty poor way. That is not the way it should be, and in the future it is going to be better, I know. In fact, a committee on this subject is just issuing a report on the Training of Hospital Executives. The Rockefeller Foundation was good enough to meet the expense of such a committee. Dr. Edsall was the chairman, and certain hospital men and women composed the committee. We employed an executive secretary, who was paid by the Rockefeller Foundation, and who went about the country learning what he could on the subject. He has just written a report, which will be published within a month, I think. It is in the hands of the printer now. That report, I can't go into in detail, advocates a training of men and women for this work, so that in the future those who go into hospital administration shall have university education on such questions as public health, the social relation of the hospitals to the community, vital statistics, and business management, and such things as that; something that every one of you will admit that he would have been a more able man or woman, done his job better, if he had had that education. I have wished many times that I had had that education. What we have acquired, we have had to pick up by outside reading, and so on. It is hoped that some foundation, perhaps the Rockefeller, will start some such combined endeavor between hospitals and universities, and start on the training of hospital superintendents,—the Lord knows we need it.

Regarding the community hospital, of which Dr. Brown spoke, we have got to do something for our rural problem, which is getting very serious, and in many of our back country districts, as you know, they can't get a doctor without offering to build them houses, offering to pay them to come into the town. It has always seemed to some of us—these ideas are not at all original—that that thing can be met by these community hospitals. The small general hospital has grown up wherever the community has had a rich man who has given the foundation, or where the community has been urged by doctors to have a hospital, and it has grown up without any planning whatever. We have a lot of small hospitals in Massachusetts and throughout New England, and throughout the rest of the country, not more than half doing their jobs. Architects like to have hospitals built. The result is that there are little towns—and I could name half a dozen right near Boston—little towns side by side each with a hospital, whereas they ought to have concentrated all their endeavors in one good hospital, so that a patient could get all those things which we claim a patient can have and ought to

have. How can you duplicate the man at the head of the staff? How can you duplicate the expert pathologist? the facility for making metabolism tests, and all the tests? You can't do it, and you don't do it. You are misleading people. If we could study these problems, and get our hospitals where they ought to be, and concentrate all the resources of a community on the right side, in one place, and bring to them the skill which they need, and from that centre send out all your visiting nurses, and to that centre bring all your skilled men; perhaps once a week from some larger centre have a man go down and do the tonsils and adenoids for that hospital, or a man to go down and do the orthopedic work, and have clinics,—then they could have the best of service in that one place and from that centre. You can educate your community in these health matters, and educate them to demand the kind of service they ought to have and need in the way of hospital service.

DR. HOWLAND: One of the chief things I had in mind in asking for a paper on this subject was to bring out, if possible, what the hospitals are doing to educate the people of the community; not merely in caring for the sick and educating doctors, but what they are doing to educate the people in regard to diseases. The Harvard Medical School has for some years given public lectures in which specialists talk to the community on various health problems. What is being done throughout New England, away from the big educational centres, in educating your own community, by the hospitals? Are you getting your doctors to teach the people the importance of early diagnoses and treatment, the dangers of pregnancy, and how to ameliorate those dangers? Will some of you not tell what you are doing?

DR. STETSON, Greenfield: I plead guilty. I don't think we are doing very much—not as much as we should do. One or two things that we do is in the education of our own nurses. We have improved very much in five years in that respect, and that, I think, is something toward the education of the public, indirectly. We have once a month a visit from a representative of the Northampton Insane Hospital, and generally once a month a visit from a representative of the hospital for epileptics. Those men see anyone who desires to see them in reference to any nervous or mental ailment, either of themselves or any of their family. There are a number of persons who are insane, or were insane, or epileptics, who are out on parole, and they are asked to report at these times for observation, and to meet the representatives of the hospital in which they were patients.

I can most heartily commend the statement made by the reader of the paper, and also by Dr. Washburn, that the hospital has a great

deal of influence in improving the medical work as a whole, and among men not directly on the staff. They come into the hospital, and they find men on the staff doing certain things, and nurses in the hospital expect them to do the same things. But so far as the staff doing any direct instructive work, I don't think we are doing very much, except, perhaps, we have utilized the graduation exercises of our nurses to get someone to talk on some health matter. That has been of value. Dr. Richardson came up once and gave us a good deal of valuable information, and that is an occasion that a good many people remember. That is, I think, about all that we are doing.

MR. RICHARD BORDEN, Fall River, Union Hospital: I have been very much interested in Dr. Brown's paper. I have always believed that education is a much more powerful influence than legislation, and as the topic has broadened out by discussion, the possibilities of hospital education of the community seem to be much larger than has been appreciated. I think, first of all, the most valuable educative feature of the hospital is the education of doctors who graduated from the medical schools many years ago,—an education that will never stop as long as rapid progress in science goes on; and in that connection one of the most valuable things done recently is the minimum standard requirement of hospitals. We have a monthly meeting of the staff, and those staff meetings have been so valuable to members of the staff that we have concluded to make them monthly clinical meetings, open to all members of the profession. There we have a discussion of subjects, or a demonstration of certain cases under treatment. A large number of general physicians in the town come to these meetings; we have a larger attendance, I think, than the branch of the Medical Society, and I feel that a great deal is being learned by physicians at these meetings.

Coming to Dr. Howland's suggestion about the education of the public; of course I love the doctors, but I don't hesitate to express some opinions about them once in a while. Before you go much further in educating the public in provincial towns you must educate the physicians to feel that they must have regard not only to their own pocket-books but also to their professional standing in the community. Their pocket-books won't suffer if people have a high regard for their professional ability. We now find patients coming to the x-ray department, and patients inquiring about radium treatment, who come to the hospitals, ignoring their physicians, telling that the x-ray man wants to see them, etc. Through the newspapers and other ways, education is getting very broad, education as to what may be done for them in health matters; and I can't help but see that a very considerable number of the medical pro-

fession are being outdistanced in possibilities of diagnosis and treatment by the reading and talking of the public. I think it is extremely important, where it can be done, to have these mysteries of hygiene disclosed to the public by the profession. They used to know nothing, only what they read in patent medicine or quack doctors' advertisements; but they are now getting more direct knowledge of what the truth of the matter is; and where it can be done with the coöperation of the medical members of the community it is an extremely valuable thing to do. But I imagine a large proportion of these doctors come from the smaller cities, and I suspect that they have more or less of the same difficulty with medical members that I have, and that such troubles as we have are not confined to our own city.

There is another way in which, I think, the educative function of the hospital is progressing, and that is by various bodies associated with hospitals in carrying on this work. The Women's Board of our hospital has a certain definite function. It is interested, not in the professional care of the patients, but in the more or less social welfare of the patients, and quite a number of the younger women serve on those committees. So that quite a number acquire knowledge of the effect on the community of disease, and what can be done to remedy it, and I think that knowledge is being spread by younger generations in the community life.

DR. HOWLAND: I have had a feeling for a long time that the doctor in the small community did not take the attitude of not wanting to teach the public because he feared for his pocket-book, but because he was afraid, if he talked in public, other doctors would think he was advertising himself, or would be afraid that one doctor was getting ahead of another. There must be some way to overcome that; and use all the good one could get in a series of lectures.

DR. RICHARDSON: I was at a convention at Washington recently, and I heard Dr. Vaughn say that the trustees of the American Medical Association had promised to establish a popular medical journal, which I think would be of very great importance along this line. If such a journal is established, it certainly will be up to the Hospital Association to have their interests represented, and printed in this journal from time to time.

MISS DOHERTY: Not much educative work is being done by our hospital. In "Cancer Week" we had prominent speakers from Boston both at Springfield and at Holyoke. Our doctors there are very fine in speaking before our Nurses' Association. I think they have also spoken for the Parent-Teachers' Association, and various organizations where they would reach mothers, and I think, perhaps, quite a little has been done in that way. We have a child-welfare commis-

sion, under the control of the city, and the doctors there, I think, reach a great many mothers. We also have free school-age clinics, and various things of that sort, where a great deal of work is being done. We do not have popular lectures such as Boston has at the Harvard Medical School. If anything special is being done, like tuberculosis work, or any of those things, we try to do our part. We have a Tuberculosis Society and various organizations, and our doctors give their services there, perhaps to a greater extent than in some smaller towns. I have found that the doctors are very ready to do anything we ask of them.

MISS STEVENS, Laconia, N. H.: A few years ago, there was practically nothing being done in the way of educational work in the town. People came to the hospital, but we did not seem to be reaching out. We had no public health nurse, or any sort of public health work. I asked the trustees if we might send out one of our training school nurses to people, and I did that for a year. I went to different churches and told them what I should like to do, and that the trustees and the doctors were all willing to help us. I kept that up for five years, and at the end of that time the work had grown, and I felt that it was time to withdraw the training-school nurses from public service, and then the people in the town had come to feel that they couldn't get along without this work. Through the efforts of the hospital, the city has put in a full-time public health nurse and a full-time school nurse, and we now have a tuberculosis nurse, who covers our county and goes into another county.

DR. FAXON, Massachusetts General: Dr. Washburn has hit upon a subject which has come under my consideration, not from the viewpoint of the hospital, but from the viewpoint of the practitioner. I studied the question in connection with other doctors in the community where I practised, and we were led irresistibly, in our own minds, to the opinion that the solution of many problems lay in the founding of small hospitals. These hospitals would stretch out in two directions, one to the general public. They would be collecting places, and the proper places to care for very sick people and for certain kinds of sickness. They would be the places from which visiting nurses should go out. They would be the natural places from which to send forth instruction from the boards of health to the people of the communities. They would be the centres from which to educate the communities in health matters. They would also be the places where doctors would receive education from specialists, who would come to the small community once in a while, once a week, or as often as necessary. In that way, they would keep in touch with the progress of the world. The chief thing that holds back doctors and medicine and everything in the way

of treatment in the country is the fact that doctors have no time to go to larger communities for education. It isn't because they don't want to, or are afraid to, but because they don't have the time. In this way, you bring education to them, and they can get time to receive it, and will receive it, I am very sure. So I think putting forth this idea to a body of superintendents, who can, if they approve, of course, go out and spread this idea, is going to be a great help in solving these problems. It isn't an entirely original idea. I have found that others have preceded me, and that I was not the only one who had arrived at this conclusion. It seems to be a rather slowly growing idea. I hope it appeals to you, because I think it carries great promise.

MAN: One thing we have done for the education of the public has been the giving by different doctors of popular talks to women's clubs; that is rather a good field through which to give popular medicine to the public.

The only objection that I see to the small community hospital is that the men in charge must be very carefully chosen. Unless they do receive some special training for the work, they will not be well prepared. The idea is fine. Undoubtedly, there are many rural communities suffering from lack of physicians, in northern New York, New Hampshire, and Maine. Massachusetts is not so badly off. There are towns where they have had physicians in the past and have none now; where one doctor is taking care of several towns. These men don't go away, because they can't; they have all they can do if they meet the demands made upon them to answer calls. Just because they are so busy, if a small hospital is started in the community where there is a group of such men, it is rather necessary that it should have at its head a man of superior ability, and not a man who without additional training takes on additional functions for which he is not qualified.

(To be continued.)

Book Review.

Medical Record Visiting List for Physicians.

William Wood & Co.

The new edition of this record of a physician's work is an amplification of former issues. The 28 pages of tables and special information which precede the memoranda pages furnish valuable information in condensed form.

The record pages are no longer dated for any specific year, so that the diary can be begun at any time.

This record is published in sizes to cover 30-60 and 90 patients per week.

Current Literature Department.

MEDICINE, VOLUME 1, NUMBER 1.

The initial issue of "Medicine" of 210 pages, is given entirely to two excellent articles, one by Robinson on "The Therapeutic Use of Digitalis," and one by Blackfan on "The Treatment of Meningococcus Meningitis." Both articles successfully fulfill the purpose of the periodical in providing authoritative reviews of the recent advances in clinical medicine.

Robinson's presentation of digitalis therapy is comprehensive and well arranged, and clears up many misconceptions regarding the use of the drug. After a brief historical survey of the use of digitalis he discusses the digitalis group and the potency of the digitalis bodies. Animal experimentation and the newer methods of clinical study of digitalis are next mentioned. The toxic effects of the drug are described and discussed in detail. Gastric symptoms seem to be largely, if not entirely, due to a central rather than a local effect of digitalis, and are inseparable from the therapeutic effect of the heart. The toxic effect on the heart, due to an overdose of the drug, may result in irregularities of impulse production, extrasystoles, partial heart block, pulsus alternans, etc.

In discussing the occurrence of fatalities in connection with the use of digitalis bodies, the point is made that in the practical use of the drug the therapeutic dose is very close to the toxic dose, but on the average is only about 50% of the lethal dose. "The maximum therapeutic effects are probably produced in man by the administration of from 30% to 40% at most of the lethal dose."

The therapeutic effects of the digitalis bodies are divided into four groups—those on the heart muscle, those on the cardio-inhibitory mechanism, those on the blood vessels and those on the kidneys. Proofs for the direct action of the drug on the heart muscle are given in detail. The relation of digitalis to cardiac hypertrophy is left an open question. The effect of digitalis in decreasing the rate of the heart is considered to be due to stimulation of the cardio-inhibitory center and also to a depression of conduction of the cardiac impulse from the auricles to the ventricles. In individuals with normal hearts digitalis produces slowing only when the vagus center is unusually sensitive to stimulation. The evidence seems to prove that the production of heart block by digitalis can occur only in hearts in which the conducting mechanism is already damaged. The benefits derived from the production of heart block in certain types of diseases are emphasized. In discussing the evidence against any direct action of digitalis in the blood vessels, Robinson states that arterial hypertension does not contraindicate the use of digitalis, and may in fact be advantageously effected by its action. The action of digitalis on the kidneys or its vessels is said to be "as yet unsettled, although it has been abundantly demonstrated that digitalis has no diuretic action except under very special conditions."

The discussion of the use of digitalis in heart failure occupies some twenty-five pages, and concerns itself in detail with the various types of cardiac

failure, auricular fibrillation, auricular flutter, cardiac contractions of abnormal origin, paroxysmal tachycardia, heart block, myocardial insufficiency, pulsus alternans, valvular defects as such, effort syndrome, and hyperthyroidism are all considered. The point is distinctly made that in considering the therapeutic use of digitalis, it is as necessary to take into account the various cardiac derangements responsible for heart failure as it is the effects produced by the drug.

In the treatment of auricular fibrillation, where digitalis achieves its best results, the evidence at hand seems to establish the fact that ventricular slowing is brought about by the dual action of digitalis on the cardio-inhibitory center and on the conduction pathway. Cases in which auricular fibrillation follows the so-called rheumatic infections in young or middle-aged persons as a rule show the most striking benefit from digitalis. The reduction or disappearance of a pulse deficit is mentioned as an important guide for the proper dosage of the drug. The evidences of heart block or of pulsus bigeminus occurring during digitalization should be taken as immediate signs for discontinuance of the drug. Thorough digitalization of patients with auricular flutter is considered to be a valuable procedure. Premature contractions are largely disregarded except when they occur during the administration of the drug. In paroxysmal tachycardia digitalis has been proved to be of no value. In partial heart block digitalis is contraindicated. Complete heart block, however, is not a contraindication and the drug may be of value in this condition. "In myocardial insufficiency," to quote, "it is evident that digitalis is of definite value, especially where edema is present." The manner in which the drug acts in such cases is still a matter of uncertainty. Regarding the treatment of pulsus alternans there is a difference of opinion and it "would seem that in many of these cases the margin between no therapeutic effect and a serious toxic effect is a very narrow one."

In discussing valvular heart disease Robinson states that in determining the indications for the use of digitalis, valvular lesions as such should be ignored, and other evidences of cardiac disorder should always serve as the guides for use of the drug. Aortic insufficiency is not a contraindication. In mitral stenosis without arrhythmia, the mechanical condition may be benefited, as suggested by Cohn and Fraser. As to the disturbances of the nervous mechanism of the heart Robinson emphatically states that whenever the diagnosis can be established with certainty it should be considered unwise to use digitalis in the cardiac neuroses with any expectation of obtaining beneficial results.

The use of digitalis in acute infections needs further observation. The evidence at hand, however, especially in cases of pneumonia, shows that the action of the drug is the same as in non-infective conditions. It is probably of little or no value. In diphtheria there seems to be a distinct contraindication to the use of digitalis, on account of the close resemblance between the effect on the heart of diphtheria toxin and of digitalis.

In discussing the proper dosage of the digitalis bodies Robinson points out the wide ranges in the doses recommended by various authorities. He emphasizes particularly the necessity of regulating the dose of the drug by its action, and quotes Withering, the first to recognize and publish an account of the action of digitalis. Withering's advice in 1757 for the use of the drug, though frequently disregarded, is still sound. He said: "Let the medicine be continued until it either acts on the kidneys, the stomach, the pulse or the bowels; let it be stopped on the first appearance of any one of these effects." Various attempts to establish the dose of digitalis for man are described, and the work of Eggleston is mentioned in particular. Eggleston's method of administering the drug in massive doses where rapid action is desired are given

in detail, with a clear warning of the danger of this method "if digitalis has recently been given in any form or by any route." The total dosage for a single or combined massive dose in adults is calculated and Pardee's rule of giving one minim of the tincture for each pound of body weight, in a single dose, is mentioned as a logical and safe proceeding. The necessity of knowing the strength in biological units of the preparation is emphasized. The work of McCulloch and Rupe on children indicates the necessity of employing about 50% more of the drug per pound of body weight than in adults.

The question of the absorption of the digitalis bodies is discussed in full. According to Eggleston "digitalis alone is well absorbed from the alimentary tract of man. Strophanthus, convallaria, squills, etc., are alike poorly absorbed and irregularly absorbed." Strophanthus is especially mentioned as a drug that "should never be used for oral administration to man on account of the danger of serious accident." The tincture of digitalis is better absorbed than digitoxin, digitalin and digitaloin. Evidence for any important destructive action on any of the digitalis glucosides following their therapeutic administration by mouth seems to be lacking. The size of the dose of digitalis when administered by mouth, rather than the delay in the absorption of the action of the drug, is the most important factor in regulating the speed of action of the drug. Intravenous administration is rarely necessary. When such a method is indicated strophanthin had best be used. Subcutaneous and intramuscular injections are dismissed as being undesirable and of no advantage over other methods. Rectal administration is mentioned as a possibility in selected cases.

The use of the term "cumulative action" of digitalis is criticized as tending to perpetuate a misconception. That the action of digitalis persists for some time after administration is recognized, although the various bodies differ in this. The point is made that "every digitalin is a synergist of every other member of the group."

As regards the elimination of the drug, Pardee's average figure of 22 minims per day seems to afford a fairly satisfactory basis for continued medication.

Finally in discussing the various preparations of digitalis and its allies the following statements are of interest. "Of the many preparations and specialties which are offered with high claims for oral administration, none is superior to the powdered leaf, or a tincture of high grade, and most are *decidedly* inferior." "The infusion has no advantage over the tincture or powdered leaves." "None of the preparations claiming to be devoid of effects on the gastrointestinal tract should be used on that account. The absence of this effect must be viewed as evidence of inactivity, because of lack of potency or poor absorption, and if gastric symptoms are not produced the desirable effect cannot be expected." Crystalline strophanthin is the most satisfactory drug for intravenous use, provided it is protected against deterioration by regulation of its reaction, and by its being marketed in hard glass containers. Squill apocynum and convallaria as shown by White and his collaborators, have "no place in the rational treatment of heart failure." In conclusion Robinson states that "the selection of the form in which the drug is used is relatively unimportant if activity, and especially dosage, are controlled, and if the use of unsuitable members of the digitalis group are avoided."

The second article of this issue concerns itself with the treatment of meningococcus meningitis. After a brief résumé of the history of the disease and of the mortality existing before the discovery of specific therapy, Blackfan describes in detail the meningococcus and its strains and the discovery of a specific anti-meningococcus serum. In discussing the diagnosis of this disease and the importance of bacteriological proof in individual cases he points out the difficulty

of demonstrating the meningococci in subacute and chronic cases. This is also true in the presence of a block existing between the ventricles and the spinal sub-arachnoid space. An important point is made that cases do occur in which meningococci cannot be demonstrated in smears or by cultivation, but which do recover under specific therapy.

Prophylactic measures are discussed at length, with especial reference to the carrier problem. The high incidence of carriers is emphasized, and the necessity of isolation of such individuals whenever possible. Local treatment of the rhino-pharynx of such individuals seems to be of no value. Passive and active immunity for prophylactic measures are considered. The evidence at hand would seem to favor prophylactic meningococcus vaccination in epidemics.

It is of interest in considering the epidemiology of the disease to note the author's statement "that the majority of observers are of the opinion that the meningococcus gains access to the blood stream through the upper air passages and then becomes localized in the meninges."

The remainder of the article deals mainly with the details of the specific treatment of the disease. Lumbar puncture as a means of diagnosis is strongly advocated in spite of any theoretical dangers attributable to its use. The intravenous administration of serum is the method of choice. The serum should be given by the gravity method and special attention should be paid to symptoms of collapse. It is essential that the serum should be of high potency, and certain antibodies specific for the causative type of organism; that it be maintained within the cerebrospinal system at high concentration, and in direct contact with the meningococcus. Free drainage should be obtained from time to time by spinal puncture. The symptoms accompanying the intraspinal injection of the serum are outlined and more especially those connected with too rapid injection and the sudden increase of intracranial pressure.

The dosage and frequency of injection and the indication for the discontinuance of intravenous treatment are fully considered. The early intraventricular injection of serum in small infants and in patients with a thick plastic exudate, with or without hydrocephalus is recommended. For general use polyvalent sera are desirable. Drugs, except for the relief of symptoms, have proved valueless. Other measures such as venesection, the intraspinal injection of human serum and antiseptics, salt injections, the use of lumbar puncture alone are all considered and dismissed as unsatisfactory. In subacute and chronic cases the use of vaccines would seem to be indicated as worthy of trial.

Hydrocephalus, as a complication of the disease, is discussed fully, and the necessity of intraventricular treatment is clearly pointed out. In chronic cases with obstructive hydrocephalus, early surgical interference is indicated. Other complications and sequelae of the disease and their treatment are discussed. Serum sickness and the subject of anaphylaxis are briefly considered.

The favorable influence of serum therapy upon the disease is clearly outlined in a brief series of statistics of cases, taken before and after the discovery of specific serum. The present mortality is about 25% as compared with the mortality of 70% some 15 years ago.

In conclusion Blackfan emphasizes the great importance of the potency of the serum employed and declares that "experience has demonstrated that the commercial manufacturer cannot be permitted to determine the method of preparation and choose his own standard of potency."

POSTTRANSECTION REACTIONS.

LEAVINE and SEGALL (*Surg., Gyn. and Obstet.*, Sept., 1922) write as follows:

The compatibility of the recipient's and donor's bloods must be determined prior to each and every transfusion.

No transfusion must be done during or within 24 hours after prolonged ether anesthesia, even when the donor has been found suitable previous to the beginning of anesthesia.

Much depends upon the accuracy of the test. It is, therefore, preferable to do both the indirect test (Moss, 28) to determine the group of donor and recipient, and also the direct (Cocca, 9) test, to corroborate the compatibility of the bloods, thus checking up one test by the other.

In a very recent article Robertson and Rous (39) conclude that in cases of repeated transfusion it is necessary to test for autoagglutination in the recipient's blood, and also point out that serum separated at 37 degrees C. contains more agglutinins than that separated at room temperature, whereas agglutination is more marked at room temperature than at 37 degrees C.

[E. H. R.]

THE THERAPEUTICS OF EMETINE.

CHOPRA and GHOSH (*Ind. Med. Gaz.*, July, 1922) present a valuable paper from the pharmacological laboratory of the Calcutta School of Tropical Medicine on the therapeutics of emetine. They emphasize the fact that emetine is a very powerful drug, having a toxic and cumulative action. Its value has been fully established in amoebiasis, but the administration of the drug demands most careful consideration. The patient should be kept in bed, carefully dieted, and the pulse rate watched. The drug must be stopped on the appearance of any toxic symptoms. Convalescents who have undergone a course of emetine should be allowed up gradually, and if there is any increase in the pulse rate, sent back to bed.

One grain subcutaneously every day for 12 days will cure most cases, but a maximum of 15 grains may be given. Some physicians give half a grain by mouth in addition, making a total of 18 grains. Larger doses than this in a single course are not advised. If amoebic cysts are found after treatment the course should be repeated, but, if possible, not within one month.

Emetine-bismuth-iodide is given in three-grain doses for 12 successive days.

[L. D. C.]

A SYMPOSIUM ON CANCER AND ITS TREATMENT.

Annals of Surgery, September, 1922, contains thirteen articles on this general subject and brings the subject of the treatment of carcinoma in certain regions well up to date.

Mayo shows how the end-results in cancer are influenced by type, reaction, location, and age. He states that the views of most investigators seem to harmonize in accepting the regression or degeneration of the cells, of loss of function, and of proliferation, as the processes in cancer, together with that of chronic irritation, which are most liable to be factors in its onset. The action of x-ray on carcinoma causes a complex, physicochemical change in which the cell becomes edematous, the nuclear substance fragments, and finally all powers of cell regeneration are lost; the debris is carried away by phagocytosis and replaced by connective tissue.

Elliott makes the following statement in regard to recurrence versus metastasis:

"Careful consideration of the clinical features of the cases herewith reported fails to disclose any positive etiological relationship between the primary growth and those that developed secondarily. That carcinoma shares with many varieties of benign tumors the clinical manifestation of independent multiplicity cannot be advanced. There is no reason,

however, why more than one glandular organ should not be exposed to the exciting cause of carcinoma, whatever that may be, either at about the same time or many years after the successful removal of the initial growth. This is certainly true of persistent and long-continued mechanical or other form of irritation which is recognized as the most important predisposing etiological factor in this justly dreaded lesion.

"If, for the sake of argument, the possibility of the independent development of two or more carcinomatous foci is granted, the wisdom of the thorough excision of each focus cannot be gainsaid. While metastasis ordinarily contra-indicates surgical interference, analysis of the majority of cases herewith cited leads to the conclusion that a wide excision of carcinomatous foci without evident interdependence yields encouraging results, and the propriety of adopting such a surgical principle will, I believe, be concurred in by all."

Ochsner finds in cancer of the jaw that the destruction of the growth with the actual cautery seems to give better chances of permanent cure than excision with the knife. He is convinced that early and very extensive operation with the cautery followed by carefully planned after-treatment with x-ray or radium is quite worth while in these cases, and that occasionally even advanced cases will be permanently cured by this method.

The following conclusions are drawn by Lower regarding carcinoma of the bladder:

"A large percentage of the malignant cases are of papillary origin, which means that they were referred late to the surgeon.

"The percentage of recurrence is great whatever the method of operation, whether excision or cauterization.

"Recurrence is no contra-indication for treatment, as some of the best results have resulted from operation on cases with recurrences.

"Repeated observation after operation is absolutely essential if the mortality of carcinoma of the bladder is to be reduced.

"The good results of the treatment of recurrences are due to the fact that recurrences are nearly always local and very seldom metastasize."

Lee makes the following statement regarding the radiation of carcinoma of the breast:

"Primary inoperable carcinoma of the breast has shown good results by radiation.

"The patient must be kept under constant clinical observation.

"The type of radiation must be properly selected for each individual case. No routine prescription will suffice.

"Over-treatment by radiation must be avoided.

"Very advanced cases are unsuitable for any form of treatment.

"The palliative operation following properly planned radiation is of service in well-selected cases.

"A co-operating Social Service Department makes a follow-up system effective and gives humanitarian relief to the hopeless cases.

"The results to date are very gratifying and encouraging. As the disease itself and the technique of radiation becomes better understood, we believe that more and more satisfactory results will follow, and that the possibility of still further control of the disease by radiation may ultimately be realized."

Jones and McKittrick present a very well-stated and analyzed article on carcinoma of the rectum, and describe in detail the type of operation fitted to the various types of carcinoma in patients in varying conditions of health.

Davis analyzes the results in carcinoma of the cervix and stands firmly for the use of pan-hysterectomy as opposed to radium in early cases of this disease.

THE NEW STATE HOSPITAL FOR MINOR WARDS.

The opening of this new hospital at Canton is an event of more than local interest as it marks progress in the remarkable work of the commonwealth of Massachusetts in its care of the afflicted and neglected children, a work in which Massachusetts has always been preeminent and a leader. The minor wards in our Commonwealth have for many years been placed under careful supervision, not grouped in large institutions but in carefully selected private homes; but diseases incidental to childhood necessarily occur in the several thousand minor wards placed in families throughout the State. These children have been taken, when ill, to local private hospitals or placed under the care of physicians of the vicinity or in many instances sent to the State Infirmary, already overcrowded with the care of adults. For many years it has been thought desirable to establish separate provisions for this group of children. After the proper legislation for the purpose, steps were taken for the erection of a hospital for sick minor wards at Canton, under the direction of the State Department of Public Welfare, and the immediate supervision of the trustees of the Hospital School for the care of crippled children. The excellent record of this latter institution in the treatment, cure and education of crippled children, with marked economy in administra-

tion and in effort, seemed to justify the action of the legislature.

The trustees of the State Hospital School for crippled children hesitated in assuming the additional responsibility of the care of sick minor wards, as they were unwilling to impair the excellence of their work in the education of the physically handicapped. It was, therefore, stipulated that the two divisions of work should be sharply separated, although for economy of administration, association in the direction of the two institutions might be desirable. It is with this understanding that a new hospital has been built under the direction of the superintendent of and in close vicinity to the school for crippled children. It is unnecessary to refer here to the remarkable work already done at Canton in the education and surgical and medical care of those children afflicted with orthopedic diseases, but reference should be made to the equally unusual work in providing an efficient method of ventilation which secures for the tuberculous and slim crowded children absolutely fresh air at all times. In almost all of our schools and hospitals the need of fresh air is either entirely disregarded or made imperfectly in a way satisfactory to the plans of the sanitary engineer but entirely inadequate to the physician. This fact can be determined by anyone visiting the wards of any hospital in the winter in the early hours of the morning or late at night from one to three, or in visiting our public schools at the hours of crowded activity. The theory of ventilation, which has seemed satisfactory to the sanitary engineer, is based on the plan of plenum or exhaust method of removing carbon dioxide. The complete inadequacy of this method needs no description, as it is demonstrable in practical experiences.

The trustees of the Canton State Hospital School were fully aware of the need of furnishing fresh air to the children placed under their care and they erected buildings furnished with direct roof ventilation except in a few school rooms where they were obliged by the State laws governing school rooms to use an indirect system. As by smoke experiments the latter method was shown to be absolutely imperfect, open air school was provided. The result proved in the many years' experience of the school, the wisdom of the plan of the trustees of the institution. Adenoids, tonsils, threatening disastrous results have returned to normal and no operative interference has been necessary. In the twelve years' work at the school there has been a marked absence of respiratory diseases and a notable freedom from contagious diseases, although exposure from the visits of parents and the entrance of new patients was unavoidable. The general health of the children, their activity and development in energy as well as ruddy appearance was remarkable. It is for this reason that in planning the new hospital the trustees

stipulated that in their opinion it was essential that the building should not be constructed according to the ordinary lines of hospital construction with flat ceilings and corners impossible of adequate ventilations by the indirect method. The experience obtained in the erection of several buildings, both of one and two stories, enabled the trustees to construct a building to house at once a hundred patients at a minimum cost but of maximum efficiency with necessary laboratories completely equipped to furnish fresh air night and day in all weathers without exposure of the patients and without reliance upon balconies not always practical in the worst weather. To all patients placed in the institution the efficacy of the plan of ventilation is without question, as can be seen in several of the buildings already erected, but the plan is more thoroughly carried out in the new institution and the ventilation has been tested before the occupancy of the hospital by thorough smoke tests. There is in the institution also excellence in planning for economy of administration and in the presentation of well lighted, attractive rooms and corridors.

THE NEW ENGLAND TUBERCULOSIS CONFERENCE AT AUGUSTA, ME.

THE conference opened Thursday, September 28th, in the morning, with addresses of welcome by Maine officials and health administrators with appropriate responses from Massachusetts, Canada and National Tuberculosis Association representatives.

At the meeting of the Medical Section on Thursday afternoon, heliotherapy was the striking subject. Dr. Harry Lee Barnes, Superintendent of the Rhode Island State Sanatorium, presented a study of the apical changes of the lung based on a study of 1,111 patients at his institution. Dr. Hugh B. Campbell, Superintendent of the Norwich State Sanatorium, and Dr. Edward J. Lynch, Superintendent of the Shelton State Sanatorium, Connecticut, continued the discussion on x-ray diagnosis, agreeing that it should not be used independently, but is of great value when employed in cooperation with other means. The emphasis of the session was laid on the success of heliotherapy, not only for bone and glandular tuberculosis in children, but for the pulmonary forms also. The speakers were Dr. Cole B. Gibson of the Meriden State Tuberculosis Sanatorium and Dr. John F. O'Brien, Superintendent of the Seaside Sanatorium at Niantic, Connecticut. The general claims of these speakers were that all forms of disease yield to the sun cure. Pure sunlight instead of sunlight through windows is demanded. Exposure of the bodies of the patients to out door conditions even in the coldest weather causes no discomfort if the patients are properly accustomed to the change. It was as-

serted that the intense suffering of children ill with bone tuberculosis stops quickly under heliotherapy. Surgical operations are considered unwise by these speakers for the treatment of diseased glands, and it was asserted that the removal of tonsils and adenoids instead of being beneficial led to aggravation of the symptoms.

At the same time the Nursing Section had a meeting, at which Miss Hazel Wedgewood of the American Child Hygiene Association, Washington, discussed the "Standardization of Public Health Training." She emphasized the need of a definition of public health nurse and in supplying this definition stated that she should be a graduate hospital nurse, of at least two years' training, doing any form of public work in which her training as a nurse is useful. The nurse should have a knowledge of normal health, orthopedies, mental hygiene and the causes of mal-adjustment. She should be able to recognize the early cardinal symptoms of communicable diseases. She should keep herself in good health and have clerical ability.

Miss Edith L. Soule, State Supervising Nurse of the Maine State Department of Health, set forth the "Essentials for Standardization" under a number of headings: special training in public health nursing; study of local, county, state and national health programs; close cooperation with county and state medical associations; standing rules and standard technique; careful supervision; accurate record keeping, and frequent group conferences of nurses and supervisors.

Miss Mary E. Edgecombe of the Providence District Nursing Association spoke on the "Relations of the Nurse in the Home," and spoke especially on the duties of the tuberculosis nurse.

Thursday evening the first speaker was Dr. Edward O. Otis, President of the Massachusetts Tuberculosis League, who outlined the place of the National Tuberculosis Association, speaking of the recent International Tuberculosis Congress in Washington and the work of the N. T. A. in developing ways and means for fighting the disease. Rapid diminution in tuberculosis has been noteworthy since the initiation of organized effort against it, but in the opinion of the speaker there will be a minimum of the disease so long as human nature is what it is and people are neglectful of its beginnings. He emphasized the need of protecting the health of children so that in later life they may not develop tuberculosis, and approved the present methods of surveys and the advantage of co-ordinating health agencies for the eradication of tuberculosis.

Dr. B. L. Bryant, Secretary of the Maine Medical Association, outlined the work of his organization, which has established an advisory health committee of the three state-wide organizations,—the State Department of Health, the Maine Medical Association, and the Maine Pub-

lie Health Association. An effort is under way to secure similar federations of county activities. Work along lines of periodic examinations is advocated, and effort is made to secure coöperation and support of public health nurses, and the plans contemplate a public relations committee as a clearing house for the various medical groups. Maine hopes through these measures to establish a harmonious self-supporting health unit in every community in the state.

There was a discussion on the question, "Should there be a consolidation of all voluntary health agencies?" with Dr. E. T. Merrill, President of the Maine Public Health Association in the affirmative, and Mr. Hubert M. Sedgwick, Secretary of the Connecticut Tuberculosis Commission, in the negative. Dr. Merrill's summary is that the voluntary health workers should be united in one organization with one staff, one office expense, one appeal for funds, and at the same time refer through definite committees the specialized interests of the different movements, such as the campaign against tuberculosis, against cancer, the control of social diseases, infant welfare, prevention of blindness, etc. Mr. Sedgwick feels that the "health trust" weakens the individual campaign against a disease by failing to focus the local units upon it. His attitude was not that of discouraging coördination, but combating the idea of a public health association as a cure-all for the organization weakness.

On Friday there were six meetings of sections together with meetings of affiliated associations, and in the evening a social diversion. At the meeting of the Medical Section, Dr. J. Perkins, President of the Providence Tuberculosis League, discussed "The Diagnosis of Tuberculosis," bringing out the point that the diagnosis of tuberculosis is not a science, but an art. Dr. Estes Nichols of Portland, late Lieutenant Colonel, M. C., U. S. A., spoke on occupational therapeutics for tuberculosis, illustrating his talk with stereopticon views. He emphasized the point that occupational therapeutics will bring comfort and happiness, and strengthen morale of the patient.

Dr. D. C. Jarvis of Barre, Vt., presented a paper on dust inhalation, carrying further the researches that have already been published.

At the meeting of the section for secretaries and nurses, the procedure in all the New England States was set forth by someone connected with the State Board of Health.

At the meeting of the Sanatorium Section, Dr. Henry D. Chadwick, Superintendent of the Westfield State Sanatorium, spoke on "Tuberculosis of Children." He called attention to the fact that the infantile form of tuberculosis usually results fatally where the infection occurs before the age of two years. From this point on there is a steadily increasing immunity. After the age of five the juvenile form of tu-

berculosis largely predominates. This he characterized as "a golden interval of low mortality" between the infantile form and the adult form. The adult type of tuberculosis rarely develops before the age of twelve. His paper discussed the points on which the diagnosis of the various kinds of tuberculosis, especially the juvenile, should be based.

Dr. Thomas A. Foster of the Children's Hospital at Portland emphasized the need of special wards to care for children with tuberculosis of the bone. It is generally possible to effect a cure of a child with this form of disease if he can be kept long enough under proper supervision.

One of the afternoon sessions on Friday was devoted to the Christmas Seal Sale, with Mr. Basil G. Eaves, Campaign Secretary of the National Tuberculosis Association, chairman.

The concurrent session was that of the health officers, with Dr. Eugene R. Kelley in the chair, at which Dr. Charles Dalton, Secretary of the State Board of Health of Vermont, spoke on the relation of the voluntary health worker to the state and local health officer; Dr. Thomas Tetreau of Portland, on the enforcement of health laws, and Dr. Howard A. Streeter, Health Officer of Manchester, New Hampshire, spoke on the question of politics and the health officer.

In the evening the great social event of the meeting took place in the State House in the form of a husking bee.

Saturday morning was devoted to two general topics—general consideration of health, by three speakers, and the discussion of rest cure in the home treatment of tuberculosis by Dr. S. Adolphus Knopf of New York. The concluding exercise was a Modern Health Crusade luncheon at the Augusta House on Saturday noon.

THE MASSACHUSETTS MEDICO-LEGAL SOCIETY.

This society has been in existence 45 years, it meets every four months, on the same date and in the same place as the Council of the Massachusetts Medical Society. Its active membership consists of the Medical Examiners and Associate Medical Examiners of the State, with honorary membership of experts in various branches of legal medicine, members of the medical or legal profession who have contributed to the advancement of legal medicine, and retired active members.

The Society was founded in 1877 and in earlier years its work was fostered and largely contributed to by the revered Professors, Edward S. Wood, F. D. Draper and Wm. F. Whitney, and many men of ability who served in various sections of the state.

In absence of any central controlling body the Medical Examiners have found the Society to be the only means whereby anything approaching uniformity of procedure in the various districts could be attained and it has rendered a notable service to the Commonwealth by bringing the Examiners of the remotest districts into intimate contact with those of the Metropolitan areas and with the best teachers of legal medicine.

The Massachusetts law places very large discretionary powers upon those medical men whom she honors by appointment to the office of Medical Examiner and it can be fairly claimed that those powers have never been abused. Moreover, the medical investigations by expert men, often independent of and preceding, or, in cases of death from obvious unnatural cause, always supplementing those of the regular police, have been of undoubted utility in the detection of crime and convicting of the criminals. Such investigations at present play an important part in industrial accidents, accidents on the highways and railroads, deaths from alcohol, drugs or vocational poisonings, in most of which there is no criminal liability, but in which the victims are covered by various forms of insurance.

At the recent meeting—Wednesday, Oct. 4th—a subject of very great moment to the medical profession in general was considered—namely “The Medical Examiner’s Duty in Relation to Surgical Deaths.” The problem, as Medical Examiners face it, was stated by Dr. Hunt (11th Worcester) to hinge upon the interpretation of that portion of Section 38 (General Laws) which provides “if upon such view, personal inquiry or autopsy the Medical Examiner is of the opinion that the death may have been caused by the act or negligence of another, he shall at once notify—a justice—. The court or trial justice shall thereupon hold an inquest.” It was pointed out that this phraseology was adopted in 1916 in an effort to reduce the number of inquests on cases of simple accidents, suicides, etc., but the possibility of bringing surgical deaths into the class for which inquests were necessary was probably overlooked. As instances which might come to a Medical Examiner’s attention, a case of death resulting from gastro-enterostomy by an eminent surgeon in which the anastomosis was made to the large intestine instead of to the jejunum, and a case where an inexperienced operator in attempting to do a vaginal hysterectomy opened the bladder, and then proceeded to complete the operation by the abdominal route with the result that the patient died of peritonitis, were quoted from a book by Norman Barnesby. Hon. E. P. Saltonstall, District Attorney for Middlesex County and Legal Advisor to the Massachusetts Medical Society, was present as guest, and the question as to the application of the clause quoted was

referred to him. He said in part—“the mere fact that a death was caused by the negligent act of another isn’t sufficient to make it a crime, but as to reporting it the statute does not make any such distinction. It reads ‘by the act or negligence.’ If you think the death was caused by the act, whether it was negligent or not, or if death results from injury caused by negligence of another, I think you are taking great chances if you don’t report every such case. It is your duty to do it.” Specifically referring to the two cases cited he said, “it would be your duty to report such a case as that. I don’t know enough about surgery to know whether removing the womb through the vagina was a reckless thing to do. The first case was mere negligence; but if a man willfully does something which common sense should have told him he didn’t have the experience to do, I should think such a case should be reported.

“Your President introduced me as Medical Advisor of the Massachusetts Medical Society. I have not tried many cases yet, but one of the difficulties I have to overcome is the prevailing thought in the minds of the jurors that all doctors stand together, and that they are willing to go to great lengths to protect each other in suits arising from acts of carelessness, oversight or bad judgment. Now anything that you gentlemen do to encourage that prevailing opinion is going to make it harder and harder to overcome, and it is going to make it harder and harder to bring these cases into court. They have been increasing. I think anything that doctors do that is not absolutely above board, if they are not laying their cards on the table, is encouraging that feeling. I think the law requires that where we find death has been caused by a mistake—certainly by negligence—and I would almost go so far as to say a serious mistake of judgment—that such a death should be reported to the district attorney and a justice of the court or trial justice in the usual way.”

The discussion was participated in by several Medical Examiners. Some expressed the opinion that the intent of the law did not contemplate inquests on such cases. Dr. G. B. Magrath said that since the passage of the law it had been his practice in Suffolk district to report such cases, the Medical Examiner’s function being to ascertain the medical facts and form an opinion on them and the story of the case as he obtains it from inquiry. He then informs the justice, whose responsibility it is to decide whether there be criminal act or negligence. An inquest may, at the discretion of the judge, be strictly private.

This opens up interesting possibilities for control of the practice of surgery by an agency outside of the Board of Registration in Medicine. While its strict application might occasionally prove embarrassing, should it become a recognized fact that a judicial inquest would

follow every death resulting directly from a mischance of operation or anesthesia, it might well prove a valuable restraining influence upon inexperienced or injudicious use of surgery.

Another feature of the Meeting was a valuable paper by Mr. Chester H. Clark from the Internal Revenue Service upon Drug Addiction in Massachusetts and its Medico-legal Relation. This paper will later be published in detail in this Journal or in the Proceedings of the Society.

AMERICAN COLLEGE OF SURGEONS OCT. 23-27.

Boston hospitals and Boston surgeons are doing and showing their best for the annual meeting of the College with its distinguished foreign guests and the two thousand Fellows assembled.

No doubt the meeting is by way of being a success—so much has been promised in the program.

Perhaps a word may be in place here and now, to speak more at length of the College and its aims and what it has done in its nine short years of existence.

Because American Surgery, vigorous, vital, mostly fine, yet stood in need of standards more nearly fixed, because there was need of a body to represent its ideals, the American College came into being.

It was conceived in the first instance as a means of raising the standard of surgery by setting and raising the standard qualifications of surgeons.

Beginning with the original committee of ten, then with the 450 "founders"—men of acknowledged standing and character, increased by careful picking of other established surgeons, chosen by state committees as measuring up to set standards of training, skill, experience and decency, now growing by additions in the last few years from the younger men, younger Fellows, chosen for all that marked the older ones, but tested also by careful examination. So founded and enlarged, the college includes 4000 surgeons and practitioners of the surgical specialities, and stands as the acknowledged surgical body of the United States and Canada.

That part of the work is well on the way in the face of opposition expected and met and needs but a continuance of careful recruiting with standards slowly and steadily trending upward.

There was a serious evil in the "fee-splitting" so prevalent in some states that it menaced the work of the College. The practice had been frowned on from the start, forbidden by the College's fellowship pledge, and never got any foothold in its ranks. But so general was the practice in some states that it was hard for the Fellows to keep going and keep clean.

The College took up this matter and scores of meetings—doctors' meetings, meetings of

hospital trustees, public meetings—were part of an educational campaign in many places in many states, mostly conducted, and very ably conducted, by Mr. John G. Bowman, then Director for the College.

No one pretends that fee-splitting is dead but it is at least less deadly.

Because hospitals needed standards no less than the men who served them the College got the American Hospital Association to join in a campaign.

Resultant, a campaign now six years old, that has had no fanfare of publicity, that has coerced no one, that has, none the less, brought hospital standards to a definitely higher grade.

Today we all have records, pre- and post-operative diagnoses and all the rest.

They are a nuisance we all feel at times, but goodness knows they have been a blessing in disguise. Daily we sputter, and read, and sign, and then sometimes think how casual we all used to be.

We have laboratories, x-ray plants and men to run them far more generally than before this campaign set standards.

Best of all, everywhere in the country now are the stated monthly staff meetings dedicated to free discussion of hospital problems. Six years ago such meetings were held by few hospitals. Nothing has been more helpful than this simple innovation in promoting cooperation and efficiency.

Hospitals already half standardized and in order, and the work progressing.—what next?

Next comes surgical teaching and training with much to be done and changed.

The schools are doing their best with undergraduate training and one wonders sometimes if they are not doing too much; at all events they are not the immediate concern of the College.

It is the graduate training, the training of a decade and more after medical school and hospital internship that concerns us most.

Has not our teaching carried out by the written word and the open clinic contained a bit more propaganda, a bit less sound surgery than it should?

It is not long since that Codman, talking ceaselessly of end-results, was as one crying in the wilderness.

This year we are again pledged to report for publication a year later all the end-results of cases operated on before the visiting surgeons.

That is an excellent plan but it is not all.

The emphasis in the actual presentation of clinics this year has come to be not on the operative clinic but on the "dry" clinic; we are stressing not surgical technique but surgical results—for the dry clinics mean only this,—that the surgeon shows what he has done, and finished, and talks withal what he has learned and is ready to pass on to his Fellows, with demon-

strated reasons why they should receive it, or why not.

Surgery up to a few decades ago was the exhibition of the marvellous technical skill of the master.

It was in a way a show.

Times have changed.

The surgeon today, not less skillful, recognizes that the logical thing to present is *not a surgical show but a surgical "show-down."*

That he is ready to do this represents a changed sense of values which the College has had no little share in promoting.

NEWS ITEMS

DEATH RATE IN BOSTON.—During the week ending Oct. 14, 1922, the number of deaths reported was 192, against 188 last year, with a rate of 13.11. There were 37 deaths under one year of age, against 22 last year. The number of cases of principal reportable diseases were: Diphtheria, 83; Scarlet Fever, 24; Measles, 37; Whooping Cough, 50; Typhoid Fever, 4; Tuberculosis, 33. Included in the above, were the following cases of non-residents: Diphtheria, 21; Scarlet Fever, 4; Typhoid Fever, 1; Tuberculosis, 4. Total deaths from these diseases were: Diphtheria, 2; Scarlet Fever, 1; Whooping Cough, 2; Typhoid Fever, 1; Tuberculosis, 14. Included in the above, were the following cases of non-residents: Diphtheria, 2; Typhoid Fever, 1; Tuberculosis, 1.

THE ONE HUNDREDTH ANNIVERSARY OF THE BIRTH OF PASTEUR.—The New York Academy of Medicine has organized a celebration of the 100th anniversary of the birth of the late Louis Pasteur, which is to consist of a public exhibition, in the building of the Academy, commencing on December 27, 1922, the anniversary date, and culminating at the end of a fortnight in an evening of public addresses by distinguished members of the medical profession. The exhibition will consist of a collection of Pasteur memorabilia, such as books, manuscripts, photographs, engravings, medals, etc., illustrating the life work of Pasteur.

THE ANNUAL MEETING OF THE Cambridge Anti-Tuberculosis Association was held Oct. 10 at the Phillips Brooks House. The report of the year's work was read by the Executive Secretary, Mrs. Mabel Greeley Smith, and of the East Cambridge Health Center by Mrs. J. G. Thorp. The chief activities reported upon were: Cooperation with the Cambridge School Committee in the support of two summer day camps for undernourished children with an attendance of 312. Nutrition work in public and parochial schools. The beginning of Occupational Therapy at the Cambridge Tuberculosis Hospital. Health Center in the foreign section of the city. Educational work.

Officers Elected for 1922-1923: *President*, Eugene A. Darling, M.D.; *Vice Presidents*, Mrs. Rufus P. Williams, Edward A. Andrews; *Secretary*, Miss Louise W. Jackson; *Treasurer*, Miss Eva H. Bowe, Harvard Trust Company, Harvard Square.

Board of Managers: Rev. James T. Addison, Sumner C. Andrews, M.D., Rev. Hugh F. Blunt, Mrs. Raymond Calkins, Miss Bernice W. Cannon, Merrill E. Champion, M.D., Mrs. Leslie L. Cleveland, Hiram W. Colton, Bronson Crothers, M.D., Arthur Drinkwater, M. E. Fitzgerald, Rabbi Aaron Gorovitz, Thomas Hadley, Rev. Frank O. Holmes, Mrs. Edward Ingraham, Harry W. Joel, Mrs. Oliver D. Kellogg, Mrs. Kirsopp Lake, Mrs. Herbert Langfeld, Roger I. Lee, M.D., Felix McGirr, M.D., Miss Penelope B. Noyes, Mrs. J. Arnold Rockwell, Mrs. Charles R. Sanger, Mrs. Winthrop Slade, John J. Smith, M.D., John H. Taylor, M.D., Mrs. Joseph G. Thorp, Mrs. Charles P. Vosburgh, Joseph M. Wadden, M.D., George C. Whipple.

PLYMOUTH DISTRICT MEDICAL SOCIETY.—The regular quarterly meeting was held Thursday, October 19th, at 11 o'clock, at the Brockton Hospital. There was an opportunity to inspect the hospital. At 10 o'clock there were Surgical, Medical and X-ray Clinics. Speaker: Dr. Lesley H. Spooner, of Boston; subject: "The Specific Diagnosis and Treatment of Lobar Pneumonia."

BEVERLY HOSPITAL.—A demonstration clinical meeting was held at the Beverly Hospital Tuesday, October 17, 1922, at 4 p. m. Interesting cases were shown and discussion followed.

REGISTRATION OF NURSES.—Two hundred and ninety-seven graduate nurses were present during the October examinations conducted by the Board of Registration of Nurses.

THE REGULAR MEETING OF THE Springfield Academy of Medicine was held Tuesday, October 10, at 137½ State Street, at 8:30 p. m. Dr. Wyman Whittemore of Boston read the paper of the evening, entitled "Some Surgical Diseases of the Chest."

DINNER TO DR. FAXON.—On October 11th a dinner was given at the St. Botolph Club to Dr. Nathaniel Faxon, who is about to leave his position as Assistant Administrator of the Massachusetts General Hospital in order to assume the duties of Director of the Strong Memorial Hospital in Rochester, New York. Dr. Faxon will have oversight of the building of the hospital, for which a provision of ten million dollars has been made. The Strong Memorial Hospital will be connected with the School of Medicine and Dentistry of the University of Rochester. The dinner was given to Dr. Faxon by his

friends at the Massachusetts General Hospital. There were many expressions of regret for the loss of his services here, and at the same time many congratulations because of the splendid opportunity which he will have in Rochester. A cigarette case was presented to Dr. Faxon by his friends as a token of their great appreciation of his work at the Massachusetts General Hospital and as an expression of their personal esteem.

Miscellany.

INFANT MORTALITY IN THE BIRTH REGISTRATION AREA OF THE UNITED STATES.

The Department of Commerce will soon issue a bulletin, based on 1921 figures compiled by the Bureau of the Census, showing for each State and each city in the birth registration area the number of births and the infant mortality rate, together with figures for 1920 for comparison. These 1921 figures for a population of 70,425,705 show 1,714,261 births, 825,511 deaths at all ages, and 129,588 deaths under 1 year of age, which give a birth rate of 24.3 per 1,000 population, a record low death rate of 11.7 per 1,000 population, and a record for low infant mortality rate of 76. In 1920 the rates for the birth registration area were: Birth rate 23.7 per 1,000 population; death rate 13.1 per 1,000 population; and infant mortality rate 86.

For the State the lowest 1921 infant mortality rate (51) appears for Oregon, and the highest (98) for Delaware; for cities of 100,000 population or more the lowest infant mortality rate (50) appears for Portland, Oregon, and the highest (114) for Fall River, Mass.

1921 birth rates and infant mortality rates for cities of 100,000 population or more in Massachusetts:

	Birth Rate.	Deaths of Infants Under One Year of Age per 1,000 Births.
Boston, Mass.	25.6	77
Cambridge, Mass.	27.6	64
Fall River, Mass.	30.7	114
Lowell, Mass.	27.8	90
New Bedford, Mass.	29.2	95
Springfield, Mass.	25.0	72
Worcester, Mass.	26.2	77

INSTRUCTIVE DISTRICT NURSING ASSOCIATION.

MONTHLY HEALTH BULLETIN, OCTOBER, 1922.

September has, as usual, been a very quiet month, with less illness than at any other period of the year.

Two thousand two hundred and ninety-one new patients were admitted. A unique fact in

connection with these new patients was that fully one-half of them were babies or pregnant or newly delivered women.

The unseasonable activity of bronchitis and pneumonia, which marked July and August, and which, with the absence of digestive diseases, have been the outstanding features of the season, continued during September, 41 cases of each being admitted. On the other hand there were fewer cases of all the other diseases.

Continuing the gratifying decrease of the last few months, there were only three new cases of typhoid fever, a big decline from the number admitted in September of last year. Measles dropped to the lowest point in months, twenty-nine cases, but whooping cough increased, twenty-eight cases, as compared with four of last September.

The baby clinics showed an unusually good attendance.

A MODEL MEDICAL MEETING.

A program of the Second Annual Clinical Meeting of the doctors of central and western Alabama has been received. The subjects discussed embraced those which are especially useful to those physicians who are striving to give most efficient service.

Surgery, general medicine and public health problems were well covered.

Officers of medical societies who are responsible for details of meetings could use the information found in the program to advantage.

Alabama has certainly created a standard which could be adopted in a general New England meeting.

UNION DES FEMMES DE FRANCE.

This section of the French Red Cross has had a remarkable career. During the war, in addition to other activities, it is credited with the following achievements:

It maintained 400 hospitals with a total of 32,000 beds, and afforded in all 17,300,000 days maintenance. They organized the voluntary co-operation of 775 Red Cross doctors and of 20,000 nurses, of whom 1,000 were attached to nursing units in the Army Zone (administrative personnel not included).

Ten doctors and 55 nurses died at their posts; 310 were awarded the Croix de Guerre; 51 received the Legion of Honor, and 70 were awarded foreign decorations.

Four hundred and two U. S. F. F. nurses served with military hospitals in Morocco (Rabat, Casablanca, Meknes).

Nursing units with the army of the East, and in allied countries counted 90 nurses; 70 nurses went to Russia.

A hundred model ambulances were placed at the disposal of the Army Medical Service; 30,000 wounded were transported in the Paris district alone; a convoy of motor stretchers was in operation for a period of two months, and undertook the transport of 100 severely wounded men.

Station canteens undertook the despatch of parcels to soldiers at the front, and to prisoners of war throughout the duration of hostilities. In Paris alone, 165,000 parcels were dealt with. An information service was maintained for soldiers' families and relatives of prisoners of war. Soldiers on leave (French, Belgian, Serbian) were cared for, and warm clothing distributed.

OLD CATHERINE HOSPITAL.

THE following appeared as a communication in the *New York Times*, under date of Oct. 5, signed by John Haynes Holmes:

"In the city of Moscow, some two miles from the Kremlin, is a hospital which promises to be the scene of one of the most important and beneficent chapters in the history of American relief in Russia. This is the historic old Catherine Hospital, which had its beginnings in the reign of Catherine II. It was my happy fortune, this last summer, to visit this institution as a member of a committee of the American Medical Aid for Russia. The hospital had some 400 beds, with accommodations for 450 workers. In happier days it provided for a total population—patients, physicians, nurses, orderlies, servants, etc.—of more than 2,000 persons. The grounds are now rough and unkempt, and the buildings in disrepair, several of them mere ruins.

During the last year the American Medical Aid for Russia, organized under the direction of a group of American physicians, raised a fund sufficient to purchase a hospital equipment adequate for a first-class institution, which is being shipped to Russia as rapidly as possible. The society has sent in equipment and donations in kind approximately \$60,000.

Under an agreement formulated between the Moscow health authorities and the society, the old Catherine Hospital is now being put in first-class repair by the Soviet authorities and placed in charge of the American Medical Aid for a period of one year. Having already equipped the hospital, the society agrees to provision both patients and staff, and maintain the institution as a modern hospital of the highest standard.

For this great work the sum of \$200,000 is promptly needed. My colleagues and I are agreed that such an undertaking, initiated in the name at once of American science and beneficence, will make an irresistible appeal to our fellow-citizens, and enlist their generous support.

Local groups of the American Medical Aid for Russia are being organized in the great cities

of the country for the raising of funds. The officers of the organization are Mrs. Henry Villard, Chairman; Arthur S. Leeds, Treasurer; Frances Witherspoon, Executive Secretary. The National Advisory Committee of scientific men includes such names as those of Dr. Charles H. Mayo, Dr. M. J. Rosenau, Dr. Lewellys F. Barker, Dr. Haven Emerson, Dr. Harvey Cushing, Dr. Morton Prince, Dr. M. W. Ireland, Dr. Joseph Goldberger, Dr. Walter B. Cannon, and Dr. Jacques Loeb. Individual contributions may be sent to the American Medical Aid for Russia, 103 Park Avenue, New York."

SUMMARY OF WEEKLY HEALTH INDEX.

Telegraphic returns from 64 cities, with a total population of twenty-eight millions, for the week ending September 30, indicate a mortality rate of 10.7 as against 10.6 for the corresponding week of last year. The highest rate (18.0) appears for Memphis, Tenn., and the lowest (5.0) for Youngstown, Ohio. The highest infant mortality rate (178) appears for New Bedford, Mass., and the lowest for Albany, N. Y., which reported no infant mortality.

THE DIPHTHERIA MENACE.

The daily papers report that the Schick test now being used by the Boston Health Department has demonstrated that forty-five per cent. of the children are possible victims of diphtheria, when treated with toxin-antitoxin. In order to carry on the work effectively more physicians and nurses will be assigned to this work under Dr. John A. Ceconi.

THE MOSQUITO PEST.

The papers have published an alleged statement of Professor George C. Whipple to the effect that it is possible by concerted action to eliminate the mosquito in the inhabited parts of this State. This is a public health measure of importance, for in addition to the annoyance of the mosquito, irritation, loss of sleep and physical poise may lower resistance and thereby make a person susceptible to infection.

VORONOFF'S WORK ON GLAND TRANSPLANTATIONS.

ACCORDING to the daily papers, the medical profession of France is antagonistic to Voronoff's methods. He claims that great benefits have resulted from the grafting of the glands of apes onto man.

His recent lecture was largely boycotted by physicians, but a large concourse, including many women, seemed very much interested in the methods employed and assertions made.

RELIEF FOR RUSSIAN SCIENTIFIC MEN.

THE "Friends of Russian Scientists," an organization sponsored by a hundred professors and social workers in and around Boston, for the purpose of raising contributions to be known as the Gorki Fund for the Relief of Russian Scientists, has just received the following letter from Maxim Gorki:

In reply to your letter let me make the following statement: "The House of Scientists" in Petrograd is a charitable organization for mutual benefit, founded by Petrograd professors. I have the honor to be its chairman. The full name of the organization is "Committee for the Betterment of the Condition of Scientists" (Kommissia Ulutshenia Bita Utschenich—abbreviated: KUBU). Address: C. Oldenburg, Member of the Academy, House of Scientists, 27 Millionaia, Petrograd.

The "House of Scientists" brings together all the scientific workers of Petrograd—there are about 3,000 of them, and together with their families they comprise about 12,000 souls. They are undergoing great privation, and are in particular need of sugar, flour and fats.

Most of the scientists are men of middle or advanced age, enfeebled by years of undernourishment and the numerous worries of present-day life in Russia.

A ten dollar "A. R. A." parcel is a great help. The work of the American Relief Administration with Hoover at the head is one of the most brilliant pages in the history of the United States.

It seems to me that there is no need to describe in great detail the extent of misery among the scientists.

Do make every possible effort to sustain at least ten of these precious lives—precious in the broad sense of serving all mankind, the work of science being truly international and universal.

I wish you success in your good work!

M. GORKI.

SUPPLIES FOR THE CANCER CAMPAIGN.

The proceeds of the Lasker Memorial Fund, established by the family of Mrs. M. Lasker, in memory of her son, Harry M. Lasker, are this year being applied to an activity which the Society has hoped for two years to be able to accomplish. We refer to the reproduction of the colored cancer exhibit which has now been lithographed in six colors on cardboard 14 in. x 22 in. A copy of this striking and instructive exhibit will be available for each of the Society's committees (some 700 in number) and will be sent direct by the Acme Lithograph Company, New York.

The Society is ordering 1,000,000 copies of the little circular "Vital Facts About Cancer," which will also be sent about that time. Will

State and Provincial Chairmen kindly make known their wishes with regard to this shipment. If they prefer that the material not be shipped to them for transmittal to their district, county and local committees, information as to whom they should be sent, and the proportion which each should receive, will be greatly appreciated.

The letter written by Dr. Frank Billings of Chicago for special reading in churches will be printed in an edition of 500,000. May we ask once again that the State and Provincial Chairmen notify their various committees concerning this in order that arrangements may now be made with the clergy throughout the land for the reading of this short, earnest and authoritative letter? Remember that it is also suitable for reading before lodges, clubs, and all manner of assemblages where time will not permit of a longer address.

The Metropolitan Life Insurance Company has submitted and secured the Society's endorsement of another excellent cancer circular entitled "A Message of Hope." Besides supplying this to all its managers and agents for distribution to policyholders, the Company has liberally allotted 500,000 to be sent to our Cancer Committees.

HEALTH ESSAY CONTEST.

THE Board of Health of Brookline has offered the following prizes to the school children of that town for the best essays on subjects relating to health: A first prize of ten dollars, a second prize of seven dollars, to children of all grades; a third prize of five dollars to children in the grammar school grades only, and a fourth prize of three dollars for children in the six lower grammar school grades.

THE SALARY OF A HEALTH OFFICER.

THE Medical Officer of Health of the city of Manchester, England, resigned a few months since. The city fathers, in a fit of economy, put forth an advertisement for a new officer, to be paid a salary of seven thousand dollars. On the ground that this salary was not only inadequate for the responsibility attendant on the duties of the office, but also insufficient when compared with the salaries of other city officials (the town clerk receiving eleven thousand dollars), the *British Medical Journal* and *Lancet* refused to publish the advertisement. This was, of course, not only a protest of the journals but of the physicians whom they represent. As a result, the City Council took the hint, and appointed a committee to confer in the matter with a committee representing the British Medical

Association. The outcome of this conference was a compromise, the health officer to receive for the first two years seventy-five hundred dollars, for the succeeding two years, eighty-seven hundred and fifty dollars, and thereafter ten thousand dollars.

Had an inadequate salary been offered a health official in any city of the United States, we fear the profession would have found the matter of little concern. This is partly because politics, rather than preparation, enters into such appointments, but also due to the fact pointed out by an anonymous writer in the *Century*, who uses a caustic pen, but seems to know what he is writing about, that the average physician is antagonistic to, rather than favorably interested in, the local departments of health and their doings. [Excerpt from an editorial in the *New York Medical Journal and Medical Record*.]

Obituary.

ROBERT WORTHINGTON HASTINGS, M.D.

Dr. Robert W. Hastings died October 13, 1922, at his home in Brookline, at the age of fifty-six, after a short illness. For many years he had suffered with a cardiac affection.

A native of Warren, Mass., he was born August 4, 1866. Amherst gave him her A.B. and A.M. in 1888, and, entering Harvard Medical School, he graduated in 1893, then, after serving as medical house officer at Boston City Hospital and at the Boston Insane Hospital, he settled in practice in Brookline. He was instructor in Theory and Practice of Medicine and assistant in Pediatrics at Tufts College Medical School, where he was thrown into contact with the late E. W. Cushing, editor of the *Annals of Gynecology and Pediatrics*. Dr. Hastings acted as associate editor of this periodical, and on Dr. Cushing's retirement, in 1896, was editor until 1902.

Dr. Hastings served as resident physician and visiting physician to the Boston Floating Hospital, medical inspector of the Brookline Board of Health and Councilor from the Norfolk District of the Massachusetts Medical Society from 1903 to 1912.

He wrote many articles for the medical press besides his editorial duties. Among them may be mentioned "Noise as a Factor in the Causation of Disease," 1898; "Fresh Air in the Treatment of Children's Diseases," 1903; "The Boston Floating Hospital," 1903; "Clinical Study of the Bacillus Dysenteriae in Boston and Vicinity," 1904.

Dr. Hastings married, June 8, 1904, Miss Edith A. Earhart of Hagerstown, Md., who survives him, as do two daughters.

RECENT DEATHS.

PROFESSOR JAMES P. PAIGE, in charge of the Department Veterinary School of the Massachusetts Agricultural College, died Oct. 5th, 1922. He had been professor of veterinary medicine since 1891. He was a man of scholarly habits and scientific attainments, in addition to strong capacity for leadership. His legislative experience gave him influence so that he was able to secure an appropriation to build the veterinary laboratory. He was born in Prescott in 1862, graduated from the Massachusetts Agricultural College in 1882 and McGill University in 1888. He studied also in Munich. He leaves a widow, a daughter and two brothers.

FRANK WILLIAM ANDERSON, a fellow of the Massachusetts Medical Society, died at the home of his parents in Roslindale, September 29, 1922, at the age of 37. He had been associate in the section on radium and roentgen-ray therapy at the Mayo Clinic, Rochester, Minn., since October, 1920.

Correspondence.

THE WARREN TRIENNIAL PRIZE.

Mr. Editor:

At a meeting of the Trustees of the Massachusetts General Hospital, held October 13th, 1922, the following vote was passed:

Voted: That two prizes instead of one be awarded this year, the first prize to be \$500 and the second prize to be \$250; the award of the second prize this year, however, shall not be taken as establishing a precedent.

There were twenty-one essays submitted, the contestants being from the following countries: Poland, Germany, Italy, Hungary, England, United States.

The first prize went to the essay, "The Circulation in the Mammalian Bone-Marrow," written by Cecil K. Drinker, M.D., Katherine M. Drinker, M.D., and Charles C. Lund, M.D., all of Boston.

A second prize was awarded to the essay, "The Effect of X-rays on the Nuclear Division," written by James Mott Mayor, M.D., Union College, Schenectady, New York.

The reason for awarding a second prize this year was because of the difficulty in determining the relative merits of the first two papers.

Yours very truly,

F. A. WASHBURN, Director.

CORRECTION.

429 Washington St., Brighton, Mass.

Mr. Editor:

In the October 5th number, page 513, you refer to Kala Agar. Is not Kala Agar meant?

A. STANTON HUDSON.

[The JOURNAL is appreciative of the correction.—Editor.]

A DISCLAIMER.

17th October, 1922.

Mr. Editor:

In the *Advertiser* of Sunday, October 15, in an article by Elizabeth Rintels advertising the pretensions of Dr. Albert Abrams, I am quite falsely accused of having approved of Dr. Abrams' theories and methods. As I consider him one of the most gigantic frauds of the century, and as a number of persons have asked me whether I believed in Dr. Abrams, I wish to take this opportunity to state as emphatically as I can that neither he nor any other

person has had any authorization to use my name in this way, and that I feel the same disgust and indignation against his fraudulent methods that any other reputable physician must.

RICHARD C. CABOT, M.D.

MASSACHUSETTS MEDICAL BENEVOLENT SOCIETY

The annual meeting will be held at the Boston Medical Library at 5:30 P. M., on Thursday, October 26, 1922. The Council will meet at the same place at 5:15 P. M.

R. M. GREEN, Secretary.

BOOKS RECEIVED FOR REVIEW.

THE JOURNAL acknowledges the receipt of the following books for review:

Oto-Rhino-Laryngology for the Student and Practitioner. Second English edition. By Georges Laurens. Authorized English translation of the fourth revised French edition by H. Clayton Fox. Published by William Wood & Co., New York. 350 pages. Price \$4.50.

A Text-Book on Gonorrhea and Its Complications. By Dr. Georges Luys. Translated and edited by Arthur Foerster. Published by William Wood & Co., New York. Price \$6.50.

A Synopsis of Surgery. By Ernest W. Hey Groves. Published by William Wood & Co., New York. 621 pages. Price \$4.50.

Stedman's Medical Dictionary. Seventh edition. By Thomas Lathrop Stedman. Published by William Wood & Co., New York. 1144 pages, 15 plates. Price \$7.

Functional Nervous Disorders: Their Classification and Treatment.—By Donald E. Core. Published by William Wood & Co., New York. 371 Pages. Price \$6.

The Heart as a Power Chamber. A Contribution to Cardio-Dynamics.—By Harrington Sainsbury. Oxford Medical Publications. 248 Pages. Price \$3.75.

Ashby & Wright's Diseases of Children—Medical and Surgical. 6th Edition. Revised by H. T. Ashby and C. Roberts. Oxford Medical Publications. 769 Pages. Price \$12.50.

Clinical and Operative Gynaecology.—By J. M. Munro Kerr. Oxford Medical Publications. 832 Pages. Price \$15.

Studies from the Rockefeller Institute for Medical Research. Reprints—Volume XLII. Privately published. 616 Pages. Price \$2.

Kirke's Handbook of Physiology. Tenth American Revision.—By Charles Wilson Greene. Published by William Wood & Co., New York. 820 Pages. Price \$5.

A System of Clinical Medicine—Dealing with the Diagnosis, Prognosis and Treatment of Diseases, for Students and Practitioners.—By Thomas Dixon Savill. Published by William Wood & Co., New York. 951 Pages. Price \$9.

Medical Record Visiting List for Physicians. Published by William Wood & Co., New York. Prices \$1.75, \$2 and \$2.50.

The Elements of Scientific Psychology.—By Knight Dunlap. Published by C. V. Mosby Co., St. Louis. 368 Pages. Price \$3.50.

Physical Diagnosis.—By W. D. Rose. 3d Edition. Published by C. V. Mosby Co., St. Louis. 755 Pages. Price \$8.50.

Physiology and Biochemistry in Modern Medicine.—By J. J. R. MacLeod. 4th Edition. Published by C. V. Mosby Co., St. Louis. 992 Pages. Price \$11.

UNITED STATES CIVIL SERVICE EXAMINATION. X-RAY MECHANICIAN.

Receipt of Applications to Close November 14, 1922.

The United States Civil Service Commission announces an open competitive examination for x-ray

mechanician. A vacancy in the Veterans Bureau, Washington, D. C., at \$200 a month, and vacancies in positions requiring similar qualifications, at this or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

Applications.—Applicants should at once apply for Form 1800, and form for county officer's certificate, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C.

ELECTIONS AND APPOINTMENTS AT HARVARD UNIVERSITY.

The following elections and appointments of the President and Fellows of Harvard University have been consented to by the Board of Overseers:

Robert Bayley Osgood, Professor of Orthopedic Surgery, to serve from September 1, 1922. Leroy Matthew Simpson Miner, Professor of Clinical Oral Surgery, to serve from September 1, 1922. Fred Alexander Beckford, Professor of Prosthetic Dentistry, to serve from September 1, 1922. Lawrence Willis Baker, Professor of Orthodontia, to serve from September 1, 1922.

The following were appointed for three years from September 1, 1922:

Frank Turner Taylor, Assistant Professor of Clinical Dentistry. Amos Irving Hadley, Assistant Professor of Ceramics. John William O'Connell, Assistant Professor of Materia Medica and Therapeutics. Horace Leonard Howe, Assistant Professor of Clinical Orthodontia. Norman Beverly Nesbitt, Assistant Professor of Prosthetic Dentistry.

NOTE.

An unsigned criticism of an advertisement in the JOURNAL has been received. We are always appreciative of constructive criticism, but the general policy of editorial offices is to ignore unsigned communications. A written opinion only carries weight when the author is known.

THE NORFOLK DISTRICT MEDICAL SOCIETY.

A stated meeting of the Society will be held Tuesday, October 31, at the Massachusetts Hospital School, Randolph Street, Canton, at 3:30 p. m. sharp. The Hospital School is about six miles from Mattapan Square via Blue Hill Parkway, Canton Ave., past the Blue Hill Station through Ponkapog, bearing right at end of road, taking road marked Canton and Sharon, about one and one-half miles beyond, sharp left on Randolph Street. The buildings can be seen from this corner. Fellows not having an automobile will please be at Mattapan Square not later than 3 p. m., so that transportation may be furnished. Arrive at 3:30 p. m. Inspect buildings and school. Out-of-doors activities of the pupil patients of the school. Demonstration of the work and training. Inspection of the new one-hundred bed infirmary, probably the best equipped building of its kind in this country. Presentation of cases by the staff, with special reference to modern treatment of tuberculosis of the hip. Moving pictures and stereopticon. Business meeting 6 p. m.

A full attendance is urgently requested, as the work done by this institution is very remarkable. It may be well to mention that here can be found the greatest number of orthopedic cases in America.

The Censors meet for the examination of candidates, Thursday, Nov. 2, 1922.

Collation.

DISEASES REPORTED TO MASSACHUSETTS

MEDICAL SOCIETY OF THE MISSOURI VALLEY.

The thirty-fifth annual meeting of the Association was held at St. Joseph, Mo., September 21-22, 1922, under the presidency of Dr. Paul E. Gardner, of New Hampton, Iowa. The guests of this Society included Dr. Frank Smithies, of Chicago, who gave an illuminating lecture on "The Modern Meaning of Biliousness"; Dr. John B. Wood, of Kansas City, gave a most excellent paper on the "Vitamines" (illustrated by lantern slides); Dr. E. P. Shoun, of Bloomington, Ill., presented a movie picture demon-

stration of his operation for "Goiter" under local anesthesia; Dr. Norman M. Keith, of Mayo Clinic, read a very instructive paper on "Hypertension in Cardio-Vascular Disease." The session closed with a symposium on the "Early Diagnosis of Cancer."

Officers elected for the ensuing year were as follows: President, Dr. Floyd D. Spencer, St. Joseph, Mo.; First Vice-President, Dr. W. S. Stotter, Shenandoah, Iowa; Second Vice-President, Dr. Palmer Findley, Omaha, Neb.; Treasurer, Dr. O. C. Gebhart, St. Joseph, Mo. (re-elected); Secretary, Dr. Charles Wood Fassel, Kansas City, Mo. (re-elected). Next meeting, Omaha, September, 1923.

SOCIETY MEETINGS.

DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District:—Hyannis, November 3, 1922, February 2, 1923, (Annual Meeting)—May 4, 1923.

Bristol South District:—Fall River, November 2, 1922, May 3, 1923.

Essex North District:—Haverhill, (Semi-Annual Meeting)—Jan. 3, 1923, Y. M. O. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Suffolk District:—Combined meeting of Boston Medical Library and Suffolk District, November 22, 1922; December 27, 1922; January 31, 1923; February 23, 1923; March 28, 1923; Annual Meeting, April 25, 1923.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Bartoo Cooke, Hist. The date for each speaker has not been assigned.

Middlesex North District:—Meetings; Wednesday, January 31, 1923.

Worcester District meetings in Worcester, Nov. 8, Dec. 13, 1922, Jan. 10, Feb. 14, March 14, April 11 and May 9, 1923, the last named date being the annual meeting.

A joint meeting of the Worcester and Worcester North Districts will be held at the Burbank Hospital, Fitchburg, Oct. 31, 1922.

A joint meeting of the Plymouth, Bristol North, Bristol South and Barnstable Districts will be held at Lakeville Sanatorium, Middleboro, on November 9, 1922.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

Massachusetts Association of Boards of Health, October 26, 1922, Worcester, Mass., W. H. Allen, Mansfield, Mass., Secretary.

New York and New England Association Railway Surgeons, 32nd Annual Meeting at New York City, October 23, 1922, Donald Guthrie, Sayre, Pa., Secretary.

November, 1922. Massachusetts Society of Examining Physicians, (Date and place of meeting undecided), Hilbert F. Day, Secretary. National Cancer Week, November 12 to 18.

December, 1922. New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3.30 p. m., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

January, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston, W. H. Allen, Mansfield, Mass., Secretary.

February, 1923. New England Dermatological Society Meeting, February 14, 1923, at 3.30 p. m., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

March, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary.

April, 1923. New England Dermatological Society Meeting, April 11, 1923, at 3.30 p. m., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston, W. H. Allen, Mansfield, Mass., Secretary.

May, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), American Pediatric Society Meeting, May 31, June 1 and 2, 1923, at French Lick Springs Hotel, French Lick, Ind., H. C. Carpenter, Secretary.

June, 1923. American Medical Association, San Francisco, June 25-29, 1923, Alexander R. Craig, Chicago, Ill., Secretary.

July, 1923. Massachusetts Association of Boards of Health, July 26, Nantasket, W. H. Allen, Mansfield, Mass., Secretary.

*Deceased Sept. 2, 1922.

Address.

THE PHYSICIAN AND THE SURGEON.*

BY HARVEY CUSHING, M.D., BOSTON.

"Why, in God's name, in our days, is there such a great difference between the physician and the surgeon? The physicians have abandoned operative procedures to the laity, either, as some say, because they disdain to operate with their hands, or rather, as I think, because they do not know how to perform operations. Indeed, this abuse is so inveterate that the common people look upon it as impossible for the same person to understand both surgery and medicine. It ought, however, to be understood that no one can be a good physician who has no idea of surgical operations, and that a surgeon is nothing if ignorant of medicine. In a word, one must be familiar with both departments of Medicine."

"No one can be a good physician who has no idea of surgical operations, and a surgeon is nothing if ignorant of medicine." This, Gentlemen of the College, is my chosen theme, and lest you think it a novelty of my own, I hasten to add that the paragraph quoted is transcribed from writings which exist for us only in manuscript, since Lanfranchi, called the father of French surgery, who expressed this sentiment, lived two centuries before Gutenberg.

When one considers the healthy unification of Hippocratic medicine, why *was* there such

a difference in Lanfranchi's time, and must we admit that the difference he lamented still exists in ours? Does the shadow of the mediaeval schism dividing medicine and surgery, and both from the church, which originated, history tells us, in a thirteenth-century papal decree forbidding the participation of the clergy in any procedure involving the shedding of blood—does the shadow of this schism still lie upon us? What difference, after all, is there between physician and surgeon except in the kind of cases each of them chooses to treat and in the variety of therapeutics applied? And in view of many centuries of separation, do we tend toward reunion or further separation? These are questions which concern in no small degree the very existence of this College.

THE PHYSICIAN'S PROGRESS.

We certainly have stumbled along widely divergent therapeutic ways, we lay physicians and lay surgeons. The great physicians of ancient days were first of all given over to a polypharmacy inherited from the Arabians, then to the Law of Signatures with its astounding botanical therapeutics, then to a period of heroic bleedings and purgings and sweatings. Homeopathy followed, and taught the profession a much-needed lesson, and finally cellular pathology and bacteriology came to revolutionize physic by arousing a profound skepticism in regard to the efficacy, whatever the dose, of most of the drugs abundantly prescribed for symptomatic purposes. This gave to the tradi-

* Presidential Address before the American College of Surgeons, Boston, October 27, 1922.

† Cf. Henry E. Henderson's *Gilbertus Anglicus*. Privately printed. The Cleveland Medical Library Association, 1918, p. 77.

tional practices a staggering blow, and the coal-tar products with synthetic chemistry finally closed the physic-garden, drove plants, with a few notable exceptions, from the pharmacopœa, and Botany from the curriculum.

While all this was going on, much time was spent in evolving "systems" of therapeutics based upon bizarre interpretations of pathology which followed one another in succession, the Erismian doctrine being one of the last, whereby diseases were either sthenic or asthenic; and a century and a half later we still hear "asthenic states" spoken of as ones which need supporting treatment by alcohol, so that even in these dry days the physician is privileged to prescribe the drug that was Brown's personal undoing, though he lived north of the Tweed.

It is an old saying that the wisest physician is he who knows the uselessness of the most medicines. Nevertheless, in an unfortunate alliance with the apothecaries, at about the time the surgeon was entangled with the barber, the eighteenth-century physician was accustomed to write prescriptions for patients he hadn't seen, while enjoying good company in the coffee-house. Some measure of common sense in matters therapeutic was finally knocked into the profession by the growing appreciation of the self-limitation of many diseases, by the success first of Hahnemannism, and later of other cults like Mother Eddy's, which revived the therapeutic importance of a neglected principle well known in the Aesculapian temples—the influence of the mind upon body ailments, particularly when imaginary in large part, as so many of them are. Mr. Dooley once sagely remarked that "if the Christian Scientists had a little more science and the doctors more Christianity, it wouldn't make much difference which you called in—provided you have a good nurse." And there is no doubt but that Florence Nightingale and her successors have also had much to do with modifying our modern therapeutics.

But the profession has not entirely regained its therapeutic sanity under these benign influences. Those uncritical and poorly trained physicians who live in glass houses and give welcome to the prescriptions of certain pharmaceutical establishments which elbow their way to our desks on leaflets and postcards, cannot throw stones at the laity who give no less a welcome to nature-healers, herbalists, chiropractors, bone-setters, patent-mediciners, and other charlatans beyond enumeration. Little wonder that the wiser heads, both lay and professional, have about come to the conclusion that we had better limit the number of students in our schools, and let a smaller number, better trained, devote themselves to the prevention of disease, and, through public-health measures, keep the bulk of the community well in spite of itself, in much the same way that we protect our livestock.

THE SURGEON'S PROGRESS.

While all this has been going on through the centuries, in physic, the surgeon was pursuing an entirely different way, independent of tradition, and, for the most part, be it said, in rather bad company. A handicraftsman, often a rude, uncultivated, and ignorant though practical fellow of itinerant proclivities, he was rarely utilized in the schools, and when so employed, merely as the tool of the more learned and socially more respected physician. He had broken away from established authority; he ventured to write in the vernacular, and sometimes to operate without the physician's permission. Indeed, he did many unorthodox things. However, he was greatly needed, especially in time of war, as Charles V used Vesalius; as four successive Bourbons used Paré; Elizabeth, William Clowes; Charles I, Richard Wiseman; and, to give an example from more modern times, as Napoleon used Larrey. Thus he came to be respected at court, even though he was kept out of the faculties, where he was looked upon with scorn not untinged with jealousy. An outcast both of church and profession, he finally climbed into professional and some measure of social esteem about the middle of the eighteenth century by way of the barber-pole. But his long and quarrelsome alliance with the Guild of Barbers, humiliating enough, was peaceful when compared with the quarrels of the physicians and apothecaries.*

A short century after the surgeons succeeded in breaking away from this alliance with "barbery" and were readmitted into the schools on the same footing as the physician. There came Lister on the heels of Pasteur, to revolutionize, not only surgical therapeutics, but, at the same time, by the introduction of surgical cleanliness, the very hospitals in which both physic and surgery are practised. And so it has come about that while the physician today has busied himself in perfecting elaborate methods of diagnosis for many chronic disorders, he rather shrugs his shoulders over therapeutics; whereas, on the other hand, treatment by operative methods has developed amazingly, and there is no gainsaying that in the hands of some it tends to run away with itself as a therapeutic measure.

REUNION OF PHYSICIAN AND SURGEON.

There, in very rough outline, the two main

* Sir William Stokes in an article entitled "The Altered Relations of Surgery to Medicine" (*The W. Lond. Medico-Chir. Soc.*, 1888, vii, 124-7), wrote as follows:

"... In the infancy not only of the social, but also of the scientific position of the surgical profession, the injunction, such as it was, of the two co-operators (the Surgeons' and the Barbers' Company) was undoubtedly a calamity, and it helped to give the physicians the advantage which they occupied so long, and in which they were still further strengthened by an enactment made in Elizabeth's reign prohibiting surgeons from prescribing internal medicines. As a proof that the inferior position, socially and scientifically, was maintained up to a comparatively recent period, I may mention as a fact which I learned from Mr. Colles, who informed me that his father, Abraham Colles, had stated that at the commencement of his professional career in Dublin, when a consultation on any important case was held, the surgeon was not as a rule permitted to be in the room where the physicians held their deliberations; but, after the consultation was over, he was informed whether his services would be required or not."

clinical branches of Medicine, long separated both socially and professionally, have grown in ways so divergent that the fact of their origin from a common stem has become obscured by an accumulation of therapeutic débris left by a succession, on the one hand, of theorists who, like the modern endocrinologist, may perhaps see the patient as a whole, but through a mist, and by the modern surgical specialist who sees only a part, but that part so disproportionately he is tempted to remove some of it.

Should these therapeutic groups be allowed to riot in their growth unmolested, branching in all directions at will, or will they bear better fruit if grafted or fertilized or cut back remorselessly? All agree that the time is at hand at least for some judicious pruning, both in physic and surgery, and for the removal of sufficient rubbish to permit the main stem of Medicine and its roots of Science to be properly exposed and aerated. This process will be good for both root and branch, and more particularly will it benefit the branches if it has the effect of making the surgeon less of a pure technician and more of a physician, and the physician more capable of utilizing some of the minor procedures of surgery and with a better understanding of the major ones.

"In a word, one must be familiar with both departments of Medicine," and this is no less true today than in the thirteenth century or in the days of Hippocrates. By no means did Lanfranc, in the statement which has been quoted, mean to imply that physicians must practise surgery—merely that they will be the better physicians the better their understanding of surgical therapeutics; and, on the other hand, that no surgeon should be regarded as qualified to undertake operative procedures who is not primarily and thoroughly grounded in medical diagnosis. A graduate in Medicine may have a very wide knowledge of surgery or even be a successful teacher of the subject without necessarily being himself an operator, just as one may have a thorough knowledge of music without being a performer. So, also, there may be many activities in which a physician may engage, beneficial to his profession, without necessarily "practising" or prescribing drugs.

However, when in common parlance we differentiate physician and surgeon we do so only on the basis of therapeutics, and, granting the same underlying knowledge of disease, this is all that separates, from Medicine proper, homeopathy and osteopathy and all the other therapeutic cults, each of which reaches some degree of sanity so soon as it undertakes to perform surgical operations, as in time it is inevitable each one of them should do. There is nothing homeopathic about the scalpel, and when surgery was permitted to creep into this doctrinaire school it was near its end. The osteopath and chiropractor and eclectic and all the others

may beware of this, for so soon as they come to engage in surgery, then a thorough medical grounding will be necessary, so that the natural end of all such cults is, that, dead or alive, they will become swallowed in time by the general profession, distasteful as the dose may be.

METHODS OF TEACHING.

Unquestionably, what chiefly influences the direction of its growth is the way in which Medicine as a whole is taught—the way in which its various subdivisions are presented to the student, and the relative stress laid upon them. Whatever their spirit of altruism, most of our students enter the profession as a means of livelihood, and are likely to be influenced by what seems to them, given an ordinary degree of ability, to be the most likely road to an income-producing end, whether it be as a laboratory worker, or public-health official, or physician, or surgeon, or specialist of any sort. A disproportionate amount of teaching, or better and more personal teaching in one subject over another, whereby the student's interest is aroused and he begins to feel a certain amount of confidence in his knowledge, will inevitably lure in that direction the larger number.

The periodical turnover in our curricula is an evidence of the fact that faculties show a perennial dissatisfaction with existing conditions, and strive each of them to find the proper average allocation of subjects, little realizing that it makes no great difference—that the fault lies with us the teachers, not with the curriculum, for Medicine can be successfully taught from many angles if only students are properly stimulated and encouraged to observe and think and do for themselves. But what has become particularly apparent of late is that the curricular tree has become overloaded by grafting upon the clinical branches an undue profusion of specialties, few of them of fundamental importance even though they doubtless bear fruit of marketable value which dangles before the student's eyes so alluringly that he is prone to forget, or to overlook entirely, the source of origin of the specialty in general Medicine.

There has been a great reaction against this, and our supposedly more progressive schools are engaged in lopping off a number of these clinical branches. Some schools, indeed, have come to pay so much attention to the root and stem that, if we do not beware, the top will be cut back so far that there will be neither foliage nor fruit—no medical practice whatsoever—and thereby encouragement will be given to the growth of every conceivable form of quackery, which will spring up around us as have the schools of the chiropractor, to fill the depleted ranks of the profession; and the indifferent public is probably worse off than it was before. Far better than this would it be for us to send out after two years of clinical study alone, with some additional knowledge of public

health, a group of men to be licensed as Bachelors of Medicine, who at least could attend to the ordinary ailments and health of the rural districts, where public opinion is largely made and from which legislation, detrimental or otherwise to the interests of the profession in its campaign for sanitary measures, is likely to emanate.

TEACHING WITHOUT THE PATIENT.

It is a curious commentary on our methods, that, while we have come to emphasize the importance of teaching the pre-clinical sciences by practical laboratory exercises so that the student may at least have some first-hand knowledge of the scientific method and may learn to interpret and observe for himself, we have tended, if not to abandon, at least to postpone to the end of the course, these very methods so far as the clinic is concerned. To be sure, we have long outgrown the time-honored quiz as the basis of teaching, than which nothing could have been less practical. A student may know his textbook thoroughly—may, for example, give without hesitation, when asked for them in an examination, all the symptoms of that vanishing disease, typhoid fever; but if he has to utilize his own observation, senses, and wits, and dig out, himself, the essential symptoms and signs which make the diagnosis possible, he is so incapable of reversing his acquired mental processes that the idea of typhoid fever never enters his bewildered head. Only by prolonged contact with the patient at the bedside can he come to take a good history, to make a proper examination, to learn to separate the wheat from the chaff of the patient's complaints; all of which must precede the interpretation and the treatment of the existing disorder.

The so-called case system of teaching has become highly developed and popularized in certain schools—a diagnostic exercise whereby, through the process of elimination and logic, the predigested data acquired by a variety of people are presented for discussion and analysis. Such a method is excellent for training in the law, since in the legal profession one argues on the basis of authority and accumulated testimony, in accordance with which satisfactory judgments can be rendered and punishments meted out without even seeing the culprit. But the medical profession has long since broken away from dogma and authority, and though the case system, given a lively instructor, provides an interesting exercise in medical diagnosis far superior to the old-time quiz, when carried far it has the great danger of making logicians of the students, rather than practical physicians. There is some danger lest the student be led to feel that it is unnecessary, for a diagnosis, to examine the patient oneself—someone may get the history, another make a physical examination, still others supply the x-

ray findings, the laboratory tests, and so on, while all that the modern physician needs to do is to sit and expound, as did the mediæval anatomist while the barber did his dissections for him. Excellent as they may be, there is nothing practical about such exercises, and if over-emphasized they are bad for both teacher and student. For the teacher because he gets out of the habit of making his own thorough examination of the patient; for the student, who gets an impression that the diagnosis, which an autopsy may confirm or otherwise, is the only thing of importance, and treatment for the most part futile. Meanwhile the patients in their homes, in the dispensary, even those in the wards, would like to know what these professors who admittedly are having difficulty in telling, without looking at the organs, what certain people died from, are going to do to relieve their individual backaches or troublesome coughs—and perhaps it would be just as well to go to a chiropractor next time. Indeed, it takes a good deal of explaining to make clear that a lumbar puncture, bismuth studies under the fluoroscope, a blood-urea examination, metabolism observations, Wassermann tests and electrocardiograms made by as many different people, most of them technicians at that, each in their several laboratories—that all these things are necessary preliminaries to the recognition of his malady. All too often, alas, the knowledge thereby gained fails in any way to make him more comfortable or to prolong his expectation of life. The patient submits to all this and is very glad to know, in the abstract, that diagnosis has become a laboratory science which employs the modern principle of piece-work, and that the medical profession looks forward to the prevention of many existent diseases from which posterity will be exempt—but “meanwhile, doctor, what can you do to relieve my present discomforts so I may get back to work?” He is inclined like the Irishman to ask, “What has posterity ever done for me?”

THE HOME-TRAINING IN MEDICINE.

The curriculum in all of our schools still retains one essentially practical clinical course to which attention may be drawn—a course forced upon us by Boards of Registration, else even this might be curtailed or lost. It exists in the case of obstetrics, for no student is allowed to get his degree unless he has actually, himself, supervised a certain number of confinements. Here is an actual test of the medical novice's resources, the one practical test of what he may be able to do in a possible emergency in a patient's home. Nor would any of us wish to see the students robbed of this invaluable experience. On the contrary, it would be an admirable thing if the principle could be extended and every student, before his graduation, required under the control and supervision of his teachers or the district physician of the community, to engage in an actual house-to-house practice,

armed perhaps with nothing more than a clinical thermometer, a stethoscope, his fingers, and wits, supplemented perhaps by a microscope and a few anilin dyes. In this way he might learn something at least of the living conditions which modify the health of the people he now only meets in the dispensary, surrounded by all of the paraphernalia and instruments of precision supposed to be necessary for a diagnosis. It is a leaf one might take from the book of certain of the training-schools for nurses whose candidates must prove their capacity to engage in actual home-practice before they can qualify for a degree. One of our highly trained young physicians, long-time resident in a teaching hospital, recently confessed to me that he had just been through one of the most valuable experiences of his ten years of medical study. He had passed his summer on an island where was a large summer community, and in the absence of any local physician he had volunteered to hold office hours and prescribe for the needs of his fellow-sojourners, his principal armament being a thermometer, his microscope, some bandages and a few simple drugs. Never before had his powers of observation and his common sense been so thoroughly exercised.

THE SURGEON IN OTHER COUNTRIES.

It is a curious anomaly that the British surgeon, taken as a whole, is probably in practical ways a better trained physician than is the American surgeon, and yet he rarely possesses a full medical degree, and is apt to pride himself on not being called a doctor. Here, on the contrary, the surgeon, though graduated a Doctor of Medicine, not infrequently lapses into the state of being little more than a craftsman who, except for the external parts of the body, makes little or no pretence at diagnosis but expects the "internist," often without any expression of an independent judgment, to show him the way.

Different countries—indeed, different parts of the same country—vary greatly in the attitude of physicians or surgeons toward their problems. An illuminating experience of this past summer, during an all-too-short service as *locum tenens* for Mr. George Gask at St. Bartholomew's Hospital, has left me with the impression that the British student gets a more practical clinical course based upon far better training in anatomy and gross pathology than do most of our students, and that he is far less inclined to lean upon laboratory accessories in making his diagnosis. He, for a longer time and more intimately, is brought in contact with the ninety per cent. of human ailments upon which complicated laboratory tests have no special bearing, and through practical experience is apt to arrive at a reasonably sound conclusion in regard to his patient's disorder, and have a shrewd idea of the appropriate form of treatment. True, he may miss some of the more rare conditions, for which, after all, little can be done therapeuti-

cally—conditions which our students, with their vastly better laboratory facilities, might recognize in all likelihood. But, should we put side by side at work in a small town the average product of these two methods of teaching, I am inclined to think that the former would be the more resourceful, and exercise greater wisdom though possessed perhaps of less learning. And, after all, the strength of a profession, as of a nation, is represented by its average product.

CARE OF THE MINOR AILMENTS.

One looks in vain in the curriculum for a course on the common-sense treatment of minor ailments. It has been said by a wise and philosophical lay observer of the profession that so far as he can see, the only difference between the so-called "practical" doctor and the "scientific" one who has had a thorough laboratory training, is that the latter is more likely to cure his patients. But with all personal sympathy for this point of view, the community, particularly its rural portion, still has an enormous need for the common-sense practitioner, who for his four undergraduate years, under careful supervision, has seen less of complicated laboratory methods and more of the handling of sick people afflicted with the common everyday minor injuries and maladies. Otherwise we shall utterly abandon this all-important work to quacks and charlatans, who may become very skilful at it, in spite of their chicanery. I am not at all sure but that, for most of our schools, some measure at least of the French system would be best, whereby from the very outset of their course medical students are brought in direct contact with patients, and the laboratory courses are given conjointly and possibly prolonged throughout the four years.

We must somewhere and somehow strike a middle ground between over-training in the laboratory and under-training at the bedside, or the reverse. Certainly at the present time our graduates—many of them at least—no longer feel that the rôle of the country doctor, or even the general practitioner in the town or city, is at all an alluring one, even a possible one, so dependent have they become on complicated laboratory findings in arriving at a diagnosis. Unquestionably, there is an economic element which also enters into this, for a training in Medicine at the present day is unduly long and expensive, entirely disproportionate to any possible returns to be gained from a rural practice.

STRESS UPON BIOLOGY RATHER THAN ANATOMY AND PATHOLOGY.

Unquestionably, the present stress laid in this country upon the pre-medical laboratory courses, particularly those in chemistry and physiology, has greatly influenced the entire point of view of the physician, who must have a calorimeter and an electrocardiograph with a technician to operate them, if only to keep in fashion, little

realizing that they are scarcely more than research instruments. There has been much talk about the modern physiological schools of physic and surgery, and I presume this means that it is less fashionable for the clinicians to grub in the pathological and anatomical laboratories than formerly. No doubt this is the case. Anatomy and pathology just now appear to the unimaginative to have been thoroughly explored; the pioneers have taken the surface washings, and rather than dig deep for gold we prefer to look elsewhere for novelties and chance findings.

The interest of the students in these two particularly essential subjects has unquestionably flagged, for they naturally reflect the attitude of their teachers. I know no better illustration of this than the fact observed in many hospitals, that the physician is less apt than formerly to follow his patients to the operating room, and appears to be less eager than in days gone by to have a view, during life, of the pathological lesion. His place there has been taken by the radiographer who is more often on hand to see his diagnoses confirmed or otherwise. This may be for the reason that the disclosures at the operating table relate to regional pathology, and the surgeon rarely exposes lesions which will enlighten those interested in blood urea, the Wassermann reaction, calorimetric or electrocardiographic estimations.

THE PHYSICIAN-SURGEON.

Does this not mean that the surgeon has become the internist, or, put another way, that the internist (as the physician was once called) has come to do his own surgery? If this be so, it behooves the surgeon to accept the fact that he must be, primarily, a good physician—and the physician, loath as he may be to admit it, that he has undergone a metamorphosis. A year ago this College gave an honorary fellowship to the Professor of Medicine of the University of Stockholm, who had evolved an operative method, entailing great skill, whereby the adherent lung may be completely collapsed in the treatment of pulmonary tuberculosis. A distinguished member of this College, whose name we perpetuate by an annual oration, first conceived the idea of putting the diseased lung to rest, but it remained for Professor Jacobaeus, a physician, to add a further and important step to the procedure by the intrathoracic division of pleural adhesions—a step which had not been undertaken even by so imaginative and radical a surgeon as was John B. Murphy.

This, indeed, was a very significant and unusual occurrence, but, properly interpreted, the giving of this fellowship was merely an admission of the successful invasion of the surgical field by one who occupies a Chair of Medicine, and the prompt recognition of his contribution by the surgeons. Similar therapeutic invasions of what was once "internal medicine" have been made by those who because they handle a scalpel,

and are willing to set broken bones, are called surgeons, with no corresponding recognition, so far as I am aware, by societies of physicians.

There are, however, certain exceptions in the case both of individuals and of special societies—men who without disrespect are called Surgeon-Generals of Army, Navy or Marine Corps, are apt to hold membership in societies both of physicians and surgeons, even though, like the lamented Gorgas, they may be essentially sanitarians—societies, too, which recognize the inadvisability of confining their numbers to those averse or otherwise to a participation in surgery. The neurologists, for example, have opened their membership to so-called neurosurgeons, to the unquestioned benefit of those who do, and those who do not, care personally to employ operative methods of treatment. It has made the surgeons strive to be better neurologists, and given the neurologists a better conception of what therapeutic contributions their surgical colleagues are capable of making. It enables both groups better to keep their feet on solid ground, and there is no danger that the society will ever become so overrun by the surgeon as to let operative therapy fly away with itself and jump over the moon.

TENDENCIES IN PHYSIC AND SURGERY.

May I indicate the direction of our present drift, as physicians and as surgeons, by citing two recent examples from my own clinic—they are doubtless extreme examples but they will serve my purposes. Patient Number One was referred for diagnosis from a sanitarium which she had entered because of headaches, and where she had had a long and expensive sojourn. She brought with her a sheaf of records detailing special studies, made by different people, on her blood (even to the coagulation time), cerebrospinal fluid, stools, fields of vision, metabolism, alveolar air and carbohydrate tolerance. It was an impressive array of findings, all within the normal limits of error. The x-ray, however, showed a "closed-in sella." Pituitary tablets were prescribed without benefit, and she was finally advised to undergo an operation, and sent to us for that purpose. So far as could be determined, she was an over-conscientious and overworked medical librarian greatly in need of a long-postponed vacation, who incidentally had been reading a popular book on the ductless glands.

In contrast to this, let us turn to the surgeon-specialist and his worst fault, in that he often fails to see the patient whole. At the moment of this writing, Patient Number Two enters the hospital—a poor fellow who for several years has been having frequent uncinete seizures, associated with a vivid olfactory impression. Meanwhile, he has had nine intranasal operations in separate sessions—a septal resection, ethmoids, sphenoid and both antra opened and drained, turbinates removed, and finally all his teeth ex-

tracted. Of course we smell with our noses; the patient complained bitterly of a disagreeable odor, *ergo* nasal operations. What could be more simple? That he had during all this time an homonymous hemianopsia was not observed. It is a venturesome and expensive thing to consult a surgical specialist who does not see beyond his own—or his patient's—nose. And this represents for all of us the great danger of surgical specialization, when carried to an extreme, whether it be in rhinology, gynaecology, neurology, or what you will. And when the specialty removes itself from contact with general Medicine, and retires to an isolated hospital given over to a single class of cases, it is a danger scarcely to be avoided. Indeed, a ward in a general hospital, so given over, may become no less a place of isolation with its inevitable narrowing tendencies.

A wise physician and teacher, in discussing internal medicine as a vocation, once said that "the manifestations of almost any one of the important diseases in the course of a few years will box the compass of the specialties." It is no less—perhaps even more—true of surgery, and for this reason I believe it to be fundamentally essential in a general hospital, however inconvenient for the attendants, that conditions represented by the specialists shall be scattered in the wards amongst the patients still grouped under general surgery, so that staff, house-officers, nurses and students alike shall at least continue to have some due sense of proportion regarding general surgery, and surgical specialization, and the relation of both of them to Medicine.*

THE RÔLE OF THE COLLEGE.

This College of Surgeons in its short life has assumed some very responsible functions. It is playing a not unimportant rôle in international affairs by bringing together through the common bonds of professional interest the surgeons of this western hemisphere—of Canada, Mexico and South America, as well as of the United States. We have much to learn from each other. Another most important task it has undertaken is to improve, and in a measure to standardize, the work done in our larger hospitals. The modern "Survey" with public ventilation of its findings is one of our most advantageous methods of bringing about reforms. So our hospitals, some seven hundred in number, which have over one hundred beds, have been classified, with the result that improved methods of organization have been adopted which have enormously safeguarded the patient—particularly the patient destined to undergo the hazards and aftermath of an operation. It has been an expensive and laborious task, this survey, but a task well worth while, and it is now to be extended so as to

* I do not know that a proposal that my medical colleague and I exchange places for a few weeks each year will ever be acted upon, but we at least held a conjoint visit of the medical and surgical staffs once a week, and thereby endeavor to see Medicine whole, and to encourage our students to do so.

include the smaller community hospitals of over fifty-bed capacity, which are far and away more numerous.*

The College, too, has from the outset taken a vigorous stand against that abomination which prevails, it is said, in some parts of the country to such an extent that public confidence in the profession has been seriously shaken. It is a matter which bears some relation to these very trends of physio and surgery which I have endeavored to make clear earlier in this address—the surgeon becoming a pure operative technician, incapable of making a diagnosis—the physician, impoverished in therapeutic resources, and with so poor a conception of surgery that he will let out his patient to the lowest bidder willing to operate at his dictation, and divide the purse! This takes us back to the abuse of the Middle Ages. It is an abuse which could not possibly exist in any community if the surgeon was trained to make his own diagnosis, and if the physician would refuse to employ a surgeon incapable of arriving at an independent opinion regarding the necessity or advisability of an operation. For such a man is apt to be equally neglectful of what is often the most important part of every surgical procedure—the after-treatment. The physician who lends himself to such a practice is in the position of one who prescribes a dangerous drug to his patient without knowledge of its dosage or action, for there is no drug in the pharmacopoeia so dangerous as misapplied surgery.

It seems to me that it would not be a bad idea if in our tests of eligibility for fellowship in this College—tests which not only are those of moral and professional character but of operative experience and skill—we should require something more than the mere report upon a fixed number of major operations successfully performed, but should require, as well, information as to whether the diagnosis of these cases were the result of the candidate's own personal observation, or whether they were made for him by another.

We have seen that the present trends affecting the physician and surgeon are, on the one hand, toward preventive medicine and good nursing, which lessens the importance of therapeutics; on the other, in surgery, an ever-increasing subdivision and specialization which tends to magnify the importance of mere handiwork. Prevention, it is true, can also be applied in surgery. Many industrial accidents can be prevented; the rule of safety first can be followed; there would be no more gunshot wounds if fire-arms and war were abolished; if we can finally stamp out tuberculosis and eliminate cancer, there will be far less for the surgeon to do. If women did not have children, if people did not drink, if we

* It may be noted that 75 per cent. of the one hundred-bed hospitals had adopted by 1921 at least the minimum standards of acceptability, whereas in 1918 only 13 per cent. of the 692 hospitals surveyed had been accepted.

† It is significant of the success of some of the activities the College has engaged in, that laws against fee-splitting have been adopted by many State legislatures.

could only keep the policeman off his feet, the housemaid off her knees, the miner off his elbows, the aviator out of the air, the boys away from football; if all children in goitrous districts were given a little iodine, there would be less need for the surgeon. But we do not yet live in the Isle of Utopia, and however much the need of the physician may be lessened through the agency of preventive medicine, by eliminating disease as typhoid has been largely eliminated, and yellow fever, and as malaria can and will be, and many nutritional disorders, and perhaps goitre, the surgeon will continue to be needed, and I cannot see but that he must become a better and better physician.

When physicians acquire a more intimate knowledge of surgery, fewer people in need of operative procedures will be turned over to the surgeon too late, after delays caused by an inordinate number of unnecessary laboratory procedures. When surgeons are required to have a thorough grounding in general Medicine before practising their handiwork, fewer unnecessary operations will be done, and many of the evils which exist in their professional relationship with physicians will be eliminated.

All of which was said as well and more briefly by Lanfranc: "No one can be a good physician who has no idea of surgical operations, and a surgeon is nothing if ignorant of medicine. In a word, one must be familiar with both departments of Medicine."

New England Hospital Association.

ANNUAL MEETING WEDNESDAY, MAY
17, 1922, AT BOSTON MEDICAL
LIBRARY.

(Continued from page 607.)

"PRINCIPLES TO FOLLOW IN BUILDING CHILDREN'S WARDS AND WARDS FOR CONTAGIOUS DISEASES."

BY DR. D. L. RICHARDSON, PROVIDENCE CITY HOSPITAL, PROVIDENCE, R. I.

It is very appropriate that the construction of wards for children and contagious diseases be discussed together. In 1913 in a paper read before the A. M. A. at Atlantic City, the author pointed out that the same principles in the construction and management of contagious hospitals apply equally well to children's hospitals, and subsequent experience had confirmed that belief.

I need not emphasize to you how frequently infectious diseases break out in children's hospitals. I am not aware of any published statistics upon the subject, but many superintendents have stated that some of their wards have been under quarantine at least half of the time. This may be a high estimate, but even if wards are

closed because of contagious disease during only a third of the time, it results in great economic loss and usefulness of the hospital—to say nothing of the notoriety such outbreaks sometimes occasion.

The manner in which ward space is divided bears an important relation to the spread of infectious diseases, once introduced. But it is not the only consideration, not even the most important. Too much attention has been paid to construction and too little to the careful examination of every new patient, to careful supervision once the patient is admitted, and the utilization of strict cleanliness, medical asepsis, by nurses and doctors. The purpose which divisions of the ward serve, is to keep patients apart, for the danger of atmospheric infection has been conclusively shown to be of very little importance. It is assumed, therefore, that it is not necessary to discuss aerial infection as bearing upon the construction of children's hospitals of whatever kind. That it may take place at very short range, as when beds are very close together or a patient coughs in the doctor's or nurse's face, is possible. Even under such conditions contact still is the most important factor in transmission. Whatever the means employed for separating patients from physical contact, they operate also to interrupt possibilities of air infection. This statement is for the benefit of those who still cling to this favorite misconception.

To fully appreciate the proper type of construction it is necessary to briefly consider how infection enters a hospital and how it spreads after once admitted.

Ask almost any hospital superintendent how contagious diseases are introduced into hospital wards and he will invariably say, by visitors. While it will not be denied that this factor is entirely a reasonable assumption, particularly when children are allowed as visitors, it operates in a very small percentage of instances as the cause of hospital outbreaks. The real factors are the patients themselves. It cannot be too strongly emphasized that exact diagnosis of infectious diseases is impossible. There is such a large number of cases which cannot be recognized clinically. Of all patients admitted to a hospital, medical cases suffering from acute disease are the greatest menace. A child is admitted with a diagnosis of broncho-pneumonia, which is no diagnosis at all, may be suffering from measles even in the absence of a rash. Another child may be admitted for tonsillitis and really be suffering from either scarlet fever or diphtheria. Oftentimes children with a cough, treated as a bronchitis, are suffering from whooping cough. Rashes are overlooked or wrongly interpreted.

These things are pointed out to show the difficulties of the situation. In addition to mistakes in diagnosis, children may be admitted during the incubation period of some infectious disease, which not infrequently gives rise to an out-

break. And lastly, of all hospital admissions a certain percentage of patients are infectious disease carriers. For practical purposes every outbreak arises from one of these three sources.—unrecognized cases, patients in the incubation period, or acting as carriers. While visitors and packages may, theoretically, be a possible avenue of infection they can be ignored, and the investigation of the source of any outbreak should be devoted to a careful examination and supervision of all patients in the ward where the outbreak occurs.

The first important hospital rule should be, that every new patient be seen promptly by a competent diagnostician and the examination not left to an interne. In small hospitals it may not be possible to get a physician to see every patient on admission, but the patient should be treated in a separate room until the admitting physician has seen him. Every children's hospital should delegate to some resident or visiting physician the responsibility of admitting all new patients, of designating the ward or room where they shall be treated, and be called at once to see every patient who develops a rash, unexplained temperature, sore throat or other suspicious sign, as an important method of minimizing the danger of outbreaks of contagious disease.

Realizing that even the best diagnostician is liable to error, it is essential to so construct and conduct the wards that even if infection is introduced it will be limited to the least possible extent.

The spread of infectious diseases within the hospital is accomplished by actual contact between patients and indirect contact by nurses' and doctors' hands, nursing utensils, dishes, etc.

To separate the patients from physical contact three means may be employed: Putting the beds some distance apart, the interposition of a partial partition between patients, the cubicle system, and the construction of separate rooms each to contain few patients. In older hospitals which are provided with large open wards, beds may be spaced at a distance of five or six feet, or better by the construction of cubicles. Space may be conserved by the latter method, for the beds may be placed much nearer together, and yet the danger of the children coming into actual contact is slight because of the partial partition. In the construction of new hospitals, separate rooms should be constructed with enough glass in the walls to provide for easy observation and contentment of the patients by permitting them to see other patients in adjoining rooms. The installation of a large amount of glass in corridor or inter-room walls is a mistake because it is so expensive to clean and makes privacy impossible. Particularly in contagious wards one never knows what diseases to expect nor what ages will be affected, and construction should be so planned that all wards may be used for any disease or for either children or adults. Physi-

cal separation of the patients is accomplished by one of these three methods. If it is desired to keep from actual contact, direct or indirect, patients in the same room, some kind of a card should be hung on the bed to indicate this to the nurse.

Children can thus be grouped singly, or in larger groups, those who are suffering from the same disease being confined to one group, or for the purpose of dividing them in small units between which there is no contact, direct or indirect. The importance of dividing wards for children or contagious diseases into rooms to contain one, two, or three, or at most six patients, cannot be over-emphasized. The partitions separate the patients into small groups and they can be easily confined to their own rooms, which is almost impossible in a large ward even if the beds are well spaced. After the lights are out at night or even in the day it is impossible to keep them from getting out of bed and sometimes coming into contact with each other.

However, if every patient had a single room throughout hospital residence, infection might be carried from one room to another by indirect contact by nurses, doctors, utensils, etc. It is absolutely necessary to practice strict cleanliness between different groups of patients, particularly when they are in the acute process of the disease. Once infection is introduced into a ward or room containing twenty or thirty or more patients it spreads to nearly all susceptible children. If, however, the units or rooms are small, infection will be confined to those in the same room or unit and will not spread to other rooms if strict cleanliness be employed.

The ward construction to be described applies equally well to wards for general diseases of children or for one kind of infectious disease. It is of great advantage to construct all wards along similar lines so that the hospital capacity will be elastic.

Each ward or floor should be composed of small rooms for new patients, larger rooms for convalescents and the necessary utility rooms located between the two. The rooms for new patients should be designed to contain one or two beds, rarely three, and should occupy about 50 per cent. of the ward capacity. All new patients should remain in detention for one week, during which time a more accurate diagnosis can be made to determine whether the patient is suffering from a contagious disease when in a general hospital, or from other infectious disease than the one treated in that ward if in a contagious hospital. The convalescent rooms, which should accommodate one-half the patients, should not contain over five or six beds each. A child might be under observation for a week in a detention room yet after transfer to a convalescent room develop measles or chicken pox or some other disease with a long incubation period. If there are at most five other patients in the convalescent room part of them are like-

ly to be immune and the outbreak will be confined to one or two patients. This presupposes that patients in different convalescent rooms on the same floor are not allowed to mingle, that nurses' and doctors' hands be washed between rooms, and all utensils sterilized each time used.

The division of the ward floor into small rooms will be almost useless unless every room is provided with a lavatory where the nurse or doctor, after handling patients in the room, can scrub their hands in running water which can be turned on by foot or forearm valves. It is also essential that the kitchen be provided with a utensil sterilizer where all dishes can be boiled before washing, and the utility room with another sterilizer in which bed pans and urinals can be boiled after emptying. There should also be a clothes chute into which all linen, infected or otherwise, can be dropped piece by piece as occasion arises. The underlying idea is to consider all rooms occupied by patients infected or potentially infected, while the ward corridor and utility rooms remain uninfected. In the control of infection in a contagious hospital this principle is essential to maintain, and, what is more, it simplifies and makes consistent the whole technique.

The materials used for wall and floor construction are quite unimportant, for infection from them is very remote. It is advisable to use such materials as can be easily cleaned with soap and water. I am sure that excellent results can be obtained in even the temporary wood-constructed hospital if the rooms are small and provided there are lavatories, if there are sterilizers for utensils and the ward managed by a trained personnel.

Isolation wards where a variety of diseases can be treated should preferably be made up of rooms or cubicles, each containing one bed. For some purposes two or even three beds are allowable in the same room.

In every children's hospital of any size there should be an isolation ward composed of single rooms, to which all suspicious cases can be sent for observation, and where even infectious diseases can be treated if they cannot be sent elsewhere. The technique should be rigidly enforced. When you once have such a ward you will realize how indispensable it is.

By adopting this type of construction and strict cleanliness in the nursing care of patients, when a child develops measles, for instance, it is not necessary to close the whole ward. It is only necessary to isolate for observation those patients in the same room who have never had measles. In over twelve years no ward has ever been closed at the Providence City Hospital because of the occurrence of an outbreak of some infectious disease. Patients have been admitted to other rooms in the ward just as if nothing had occurred.

The nursing care as carried out in a contagious hospital is very rigid, but it can be modified for general hospitals for children.

It is not to be expected that cross-infections can be eliminated altogether from children's hospitals, but they can be lessened and the hospitals be conducted so that a whole ward need not be quarantined when a contagious disease appears in one of the rooms. The work can go on as usual after the case is disposed of and the "contacts" put under observation.

The cross-infection rate at the Providence City Hospital, a hospital for contagious diseases only, has been as follows:

1910	2%
1911	2%
1912	6.3%
1913	1.7%
1914	1%
1915	4.6%
1916	1.8%
1917	0.8%
1918	1.9%
1919	0.5%
1920	1.4%
1921	1.9%

During this period the diseases treated are as follows:

Chaneroids	21
Chicken-pox	163
Diphtheria	3,560
Diphtheria with other infectious diseases	131
Diphtheria carrier	254
Erysipelas	112
Gonorrhea, female	45
Gonorrhea, male	125
Gonorrhea, ophthalmial	19
Gonorrhea, other forms	29
Gonorrhea, vaginal	66
Impetigo	29
Influenza	459
Influenza with other infectious diseases	12
Influenza with pneumonia	88
Laryngitis, negative cultures	63
Measles	1,106
Measles with laryngeal diphtheria	41
Measles with other infectious diseases	98
Meningitis, cerebrospinal epidemic	48
Mumps	81
Mumps with other infectious diseases	4
No diagnosis	84
No disease	208
Noma	5
Other diseases	994
Pneumonia, all forms	58
Poliomyelitis, acute	64
Poliomyelitis with other infectious diseases	3
Rubella	148
Rubella with other infectious diseases	6
Scabies	35
Scarlet fever	2,752
Scarlet fever with diphtheria	57

Scarlet fever with other infectious diseases	135
Septic sore throat.....	14
Syphilis, active and latent.....	43
Syphilis, cerebrospinal	128
Syphilis, congenital	41
Syphilis, organic	10
Syphilis, other forms	1,855
Tonsillitis	539
Trachoma	12
Tuberculosis, pulmonary	1,906
Tuberculosis, meningitis	28
Tuberculosis, other forms	40
Typhoid fever	9
Typhus fever	4
Variola	31
Vineent's infection	28
Whooping-cough	391
Whooping-cough with other infectious diseases	17
Total.....	16,199

I venture to suggest, in the absence of exact statistics, that these rates, indicating the percent. of patients contracting a second disease, compare favorably with the cross-infection rates of any hospital or wards used for children suffering from general diseases.

DR. HOWLAND: Dr. Richardson's paper is open for discussion.

MR. STEVENS: I should like to ask Dr. Richardson one or two things. In his three or four-bed convalescent ward, and in his two-bed admitting ward, would he advocate a screen, either permanent or temporary, between the beds, or would he space the beds some distance apart? Would he in the cubicle, or rather the admitting single rooms, advocate the placing of water-closets in the room, or adjoining the room?

DR. RICHARDSON: Relative to the screen, I don't think it matters so much, when you have only two or three beds in a room, if you use those small rooms for admitting new patients. The danger of contact, if the beds are well spaced, say four or five feet apart, is slight, because the patients are too ill to come in contact with each other. The question of convalescence is another question. The question of having water-closets in the room or in a room adjoining the isolation room is purely a matter of expense. In a hospital for contagious diseases, 80% of the patients are under ten years of age, and by using the bed-pans now generally used in hospitals, which can be used on the bed or on the chair, we don't find any great difficulty in having the patients use them, supplying on that floor a certain number of water-closets, toilets, to which adults can go. But when you begin to put a toilet into every room, or even between every two rooms, you are adding not only to original expense, but to the expense of upkeep, and while it is perfectly all right, and a very good idea, it is just a matter of how much money you can spend.

DR. WASHBURN: Do I understand that Dr. Richardson would be willing to put toilets in patients' rooms under any circumstances?

DR. RICHARDSON: I didn't have in mind that particular question. I suppose it would be perfectly possible. I am told that in European hospitals they have them in the open ward; I think that perhaps this country might not submit to that.

DR. HOWLAND: I think Mr. Stevens had in mind a closet between rooms, so that there would be no direct contact with the room except by a door or curtain. Have you seen such installation in contagious hospitals? A. Yes, a toilet for each individual room.

DR. HERSEY: I should like to ask, if where there is a cubicle installed in the ward, and those wards are used for contagious cases, whether it is necessary to arrange further for a curtain across the end of the cubicles in case contagious cases should develop in the cubicles?

DR. RICHARDSON: The chief difficulty we have with cross-infection is with chicken-pox and measles. These are the only two diseases that we exclude from any of our open wards. It is necessary to exclude measles from the beginning of symptoms until about 48 hours after the beginning of the rash. There is very little danger after three or four days from the beginning of the eruption of chicken-pox. We interpret this rule about admitting infectious diseases rather liberally. We have tuberculosis, syphilis, cerebrospinal meningitis, and a great variety. In other words, we admit any kind of infectious disease. We use the open ward for babies with any disease except chicken-pox and measles.

DR. HERSEY: One more question: how about acute infections, the ordinary cold; in cases of that sort, with the possibility of the infection going through the hospital, would you be any more likely to prevent it by using curtains?

DR. RICHARDSON: I am very much opposed to curtains. Partitions are all right to help control children. There is no danger as far as infection through the air is concerned, unless the beds are very close. If you hang up those things, you rely on them, and won't wash your hands. The important things are to sterilize your instruments; keep the patients apart; insist on nurses and doctors washing their hands every time they pass from one group to another; sterilize dishes and utensils.

DR. BROWN: How do you explain the wide variation of cross-infection in 1912 and other years?

DR. RICHARDSON: That was a year when we were jammed full of measles, and we had more cases than we could take care of. A hospital for contagious diseases can take so many patients

and take care of them properly; when you overcrowd the hospital, you do more damage than good. A hospital superintendent should refuse to take more patients than can be well cared for; it only spreads the epidemic. In an epidemic, all he can do is to take the sickest cases, and only such number as he can take care of comfortably.

DR. HOWLAND: Tomorrow afternoon, when we visit the hospitals, if anyone is interested in the subject of isolation wards, the Boston City Hospital has just built two, one in the South Department and one in the general wards particularly for the reception of children. You will see many interesting and ingenious things there, especially the means for sterilizing, ward apparatus, steam closets, and fumigating closets for sterilizing. It seemed to me very practical and very simple.

If there is no further discussion of Dr. Richardson's paper, we will proceed with the question-box.

QUESTION-BOX.

X-RAY DEPARTMENTS.

Question: What is the most equitable way of managing an x-ray department in a small hospital where it is impossible to employ a physician for that service as full-time paid officer? What is the salary of a roentgenologist? Does he have a technician? and what are the arrangements? What is the best way to compensate doctors for reading x-ray plates?

DR. PETERS: At the Rhode Island Hospital, we have had, until within a few months, a man who gave his full time, on salary, to the work of the hospital. Recently that man has been given permission to devote his afternoon hours to his private work. He gives the hospital four or five hours in the morning to the interpretation of plates as taken by the technician. So far as I know, it has been satisfactory. This man has given his readings promptly, and his presence hasn't been missed in the afternoon, because of the arrangement and the system of having his plates there, and a dictaphone into which he could talk if the stenographer was not there. I think the work has been done satisfactorily. I have no opinion in regard to the work in small hospitals, based on experience, but I do know some small places where they employ men to go at intervals to do all the work, or to interpret the plates taken by a trained technician.

DR. DREW: Our roentgenologist is not on a salary. He receives 80% of the fees from paying patients, but he does not receive any compensation for reading plates for non-paying patients. This man feels at times that he isn't paid enough, because we insist on making only one charge for an x-ray plate of one part; that is, if we take a series of stomach plates, and they don't come out right, and the x-ray man wants to repeat them, we make only one charge, because we feel

that we ought to stand our own failures. I have had a pretty strong feeling that the x-ray man ought to be on a salary, and that there ought not to be any division of fees between the hospital and any expert connected with the hospital.

MISS BARNABY, Henry Heyward Hospital: For the past two years, we have had a Harvard Medical student who gave his time entirely to x-ray work. In the winter he came Saturdays and Sundays. One of our nurses was trained under him and under Dr. Jennings of Fitchburg, consulting roentgenologist. Then Dr. Jennings came to the hospital once or twice a week and read the plates, which are then typewritten and sent out to the doctors who send in the patients. Now the student has graduated, and we are having a regularly trained technician come in permanently, while the former student is going to give us one day a week. He has settled in Boston.

Q. Do you pay the consultant?

MISS BARNABY: He has been paid on a 50% basis.

DR. BROWN, Burlington, Vermont: Our x-ray department is highly developed for a small hospital. We pay our x-ray man 75% of all money collected for x-ray plates, and he pays his own technician. He does our laboratory work, blood work, and urine tests. The free x-ray work he does for nothing. The department has grown so, and has come to be so necessary a part of the hospital, that I think his income last year was over \$10,000; that is, for his share of the receipts. The department has grown very rapidly. It is a very necessary part of a modern hospital, and some of it, I think, might be developed in almost every hospital. Out of that money, we have paid for all of our apparatus in recent years, with some little money to the good. The department is practically self-supporting. That doesn't include overhead expenses, or bookkeeping, but it includes the cost of supplies, apparatus, and what services are required. The x-ray man, as I have already said, pays his own technician. So, on the whole, on that basis, it has been a very good thing for us, as well as a good thing for the public and for the x-ray man, who has found it worth while to devote his entire time to it. That includes all routine laboratory work.

WOMAN: Our x-ray department has been self-supporting. We have a man who does our x-ray work, and he has 40% of all charges collected by the hospital, and 25% for each extra plate. He does the fluoroscope work. The doctor who interprets the plates makes no charge.

LABORATORY CHARGES.

Question: Should pay patients be charged for blood counts and for examination of urine?

Should there be a flat laboratory charge for all patients who pay? What should the laboratory charge be, and for what?

DR. STETSON: We have recently taken this matter up. It was first taken up by the staff, and the staff held that there was no reason why a laboratory fee should not be charged, the same as a fee for the operating-room and a maternity fee, and, after considerable discussion, it was finally recommended to the trustees that a flat rate of \$5.00 be charged all patients who have any laboratory work done, with this exception, that an initial complete urinary examination and an initial white count on admission, for purposes of diagnosis, should not be charged for; that that should be done as a matter of routine. For any examination of urine, blood, stomach contents, and other laboratory work, including all laboratory service, a \$5.00 fee was recommended, and the trustees have accepted that recommendation.

Q. Does that apply to ward patients?

DR. STETSON: To everybody. The laboratory worker doesn't know who is on a free bed. If it is a free bed patient, it is charged off.

DR. HOWLAND: I think it is desirable, if there is to be a laboratory charge, that it should not be strung out into various items. Patients are irritated by a bill with many items in it. It is much more satisfactory, if you are going to have a laboratory charge, to make it an inclusive one, regardless of what you do, much or little.

DR. STETSON: All the staff, with one exception, were entirely agreed as to the charge. The feeling was that if a fee was charged for each separate service, patients might many times be deprived of necessary or desirable laboratory examinations, because the physician would feel that he did not want to run up the expense, and that better results would be obtained, and the physicians would be encouraged to use the laboratory, if a flat rate were made; and it has worked out in just that way.

DR. PETERS: Mr. Chairman, it would be interesting if those here who do make charges for laboratory work would indicate it by rising.

Response showed: Open ward patients charged, 10 hospitals; private ward patients charged, 21 hospitals; no charge for laboratory work, 20 hospitals.

ACCIDENT CASES.

Question: What can be done to collect from insurance companies on accident cases? Insurance companies sometimes pay the family, and the hospital doesn't get anything.

DR. HOWLAND: I assume that that question comes from outside Massachusetts, because here we have the Workmen's Compensation Act.

DR. SMITH: We have an industrial accident law that protects the physician and the hospital. Our Industrial Accident Commission sees that the hospital is paid and that the individual doctor is paid, even if the patient is in the hospital. We have no business relations with the insurance company.

(Woman from Waltham Hospital explains that the question refers to automobile accident cases).

MR. BORDEN: In automobile cases, where the insurance company pays the damages, the hospitals have no claim whatever against the insurance company. The insurance company assumes liability and pays damage to the person who is injured. The amount is supposed to be sufficient to include the cost of medical and hospital treatment. Fundamentally, the person to whom the hospital should look for payment is the person to whom damages are paid as the result of the accident.

WOMAN: I have been in a hospital where there were a great many automobile accident cases—six, eight, or ten such cases in the hospital at one time. We asked if there was insurance. We found the companies were very willing to see that the hospital was compensated. We never had any difficulty if the patient was insured. We never lost any money on an insurance accident case.

WOMAN: We sometimes have just such accident cases, when we are urged by the insurance company to do everything possible to save the patient's life. Then later they sometimes say that they are not liable, and the hospital has difficulty in collecting from the patient. In one special case, there was a small child who was insured. The family questioned the amount of the expense, and in that case, of course, the expense was going on before it was decided who should pay it.

DR. HOWLAND: I think Mr. Borden, who is a lawyer, very clearly covered this question, speaking from a legal point of view. We have no claim on the insurance company. The insurance company is responsible to the injured person. If there is anything to be collected by the hospital, it is from the patient. The insurance company will work with us sometimes, but we have no claim on them.

REFRIGERATING PLANTS.

Question: Who has a refrigerating plant he will recommend for a hospital of 125 beds? What is the cost of installation? and what is the expense of upkeep? Is it difficult to run? or can it be taken care of by the engineer, in addition to his other duties?

DR. HOWLAND: Miss Barnaby, you have a hospital of about 125 beds; do you have a refrigerating plant?

MISS BARNABY: Our hospital has really only 100 beds. I don't know whether our plant is large enough for a hospital of that size or not. I can't tell the cost of the installation, because it was included in the new building. Our engineer with his assistant does take care of it. We have had it running about two months. It is called the Johns-Manville machine. It is supposed to be a self-contained machine, with nothing to do but keep the motor running.

Another speaker (man) says the apparatus costs about \$7,000.

DR. RICHARDSON: We have just installed one at the City Hospital. It is too early to know whether it is going to be satisfactory or not. Most all of the wholesale beef houses and all the business men who are using refrigerating plants swear by this concern. For space we have one room about 12 by 13 feet; we have four other compartments, which all together contain about 12 by 20 feet, divided up into sections; and then we have a freezing compartment that will freeze about 1500 pounds of ice a day, and a morgue box which will accommodate three bodies. The cost of installation was \$9,000. The cost of upkeep is not yet known, probably not over \$40 or \$50 a month. Our engineer looks after it.

MR. STEVENS: I have put in a number of refrigerating plants.—200 put in by the Erie Company. One thing I try to avoid in putting in refrigerating systems in a hospital is the use of ammonia, by using other things. I have had very good success with sulpho-dioxide in refrigerating systems in self-contained systems. I use ammonia where the plant is large enough to be entirely outside of the building.

DR. RICHARDSON: We considered that matter of using ammonia. A number of people said they had had no trouble, and other people said they had had trouble. The supply pipe of liquid ammonia has a pressure of 150 pounds; we run that out of doors. The return pipe has a pressure of something like 25 or 30 pounds; that would be a slight leak, if any. The other is out of doors, so the danger is not great.

DR. FAXON: At the Phillips House, we have a Johns-Manville installation. It has been very satisfactory. It needs very little care, apparently, from the engineer. It produces perfectly satisfactory refrigeration. We also have a machine of a similar type which was put in to take care of refrigerating the ice-box in the kitchen for the General Hospital, which has also been very satisfactory.

One word of caution that I would like to suggest is, in the installation of such things in a modern fire-proof building construction, put your ice machine outside of the general frame of your main building. If you put it in the basement of the building, it will cause a little vibration to be carried up through the steel beams for

several floors. That can be avoided if you know about it.

I don't know the cost of installation.

VACATIONS.

Question: How long a vacation does the superintendent allow staff nurses? social service workers? If a nurse is to leave at the end of the year, would the hospital be expected to pay her for a vacation?

MISS SELBY, Pawtucket: We give the staff nurses one month's vacation, and I should feel that if a nurse had put in a year's work, she was entitled to her month of pay, even if she were not coming back. Our social service worker has a month.

MR. BORDEN: I quite agree that a month is a fair time for either a nurse or a social service worker, because I think the work is very engrossing, and it is in the interests of the hospital to give them that vacation. But I don't understand why a nurse who is going to leave the hospital should be paid for that month's vacation. Most people don't get a month, and the only reason why a hospital gives that length of time is that the nurse should be thoroughly recuperated. I should hesitate to give that vacation, if a nurse told me she was going to leave.

DR. HOWLAND: I think sometimes a great deal of agony is saved if you make the vacation four weeks, instead of a month; it saves quite a lot of trouble and wearing out of the calendar.

SALARIES.

Question: What salary is paid a graduate nurse in charge of the operating-room?

MISS HALL, Peter Bent Brigham Hospital: We pay \$100 a month to the supervisor of the operating-room at the Peter Bent Brigham. We have been paying that for several years. A survey made of 1115 hospitals, two or three years ago, brought out the fact that representative hospitals were paying \$100 to \$125 for operating-room supervisors. That was in hospitals of from 200 to 300 or 350 beds.

DR. HOWLAND: What do some of the smaller hospitals pay the nurse in charge of the operating room?

MR. BORDEN: Our operating-room nurse, who has three rooms, gets \$125 a month and maintenance. The nurse who has charge of the operating department of two rooms gets \$90. We expect to raise it to \$100. Our hospital doubled its capacity last year.

MISS WEST, Beverly: We pay our operating-room nurse \$85. It will be increased.

MISS BOOKER, Corey Hill Hospital: We have two nurses in operating-room. The senior has \$85; the other \$80.

RAW FOOD AND PER CAPITA COSTS.

Question: For a basis of comparison, What are the per capita costs for raw food in various hospitals? What are the total per capita costs in various hospitals for care of patients?

MR. BORDEN: At the Fall River Union Hospital, the cost per capita for uncooked food per day was \$0.36, and \$3.73 a day per capita for care of patients.

DR. FAXON: The food cost at the Massachusetts General is \$0.44 a day, and care of patients \$5.08 per day,—that is, for the General Hospital.

MISS BARNABY: With a daily average of 40 patients, the uncooked food costs \$0.50 per day per capita, and the cost for the care of patients is \$5.75 per day. We employ graduate nurses only, with attendants.

MISS SELBY: Our per capita cost for uncooked food is \$0.595 a day; the daily average cost of the patients is \$4.95.

INTERNES.

Question: How many internes, if any, should a hospital of from 50 to 75 beds have? If more than one, should their work be divided? Regarding payment of internes, do any of the hospitals represented here give an allowance to internes? If so, how much?

MISS WEST: We have averaged 50 patients, and have had one interne. He took care of the ward patients. We paid him \$50 a month. This year we are to have two internes, neither of whom will receive any salary. Their working arrangement has not yet been decided. They serve for twelve months. This year we expect to have more patients.

DR. BROWN: The American College of Surgeons allows one interne for each twenty-five patients. We give our internes \$50 when they leave, to pay their car fare out of town.

DR. RICHARDSON: Our internes have \$25 a month for the first three months; the second three months we pay \$50. They come for six months' service.

MRS. SHEPARD, Mary Hitchcock Hospital: We have a hospital of 70 beds. When we can get them—we haven't been able to for the last two or three years—we have two graduates. They act as junior and senior, junior the first six months, and senior the last three months. We have a pretty active operating-room service, three or four a day; in the last six months they assist at the operations. We do not pay them.

Meeting adjourned at 4:30 p. m.

(Dr. Richardson's Tables.)

A SPECIFIC SORE THROAT WHICH PASSED AS AN ORDINARY PHARYNGITIS AND TONSILLITIS, TREATMENT ADMINISTERED FOR SAME, WITH NO RELIEF.

BY DAVID B. MEDALIA, M.D., BOSTON.

It is my desire to publish this interesting case, to bring out the importance of a Wassermann in obstinate sore throats which do not clear up under ordinary treatments, especially persisting for a long time.

This patient, a man of forty-five, applied for examination and treatment of a very sore throat. He could not swallow except with great difficulty, whether warm or cold fluids; it pained him even to talk. History: Denies

specific disease, has been suffering from a throat condition for last few months. He was in Newport, Rhode Island, previous to his moving to Boston, where he went to a local physician, who examined him, told him he had a very bad throat, and gave him a gargle and a tonic, and told him to come back later for a urine examination. The patient did as he was instructed, for a couple of weeks. His condition became worse instead of better. He then left for Boston, and saw me the latter part of last April.

Physical examination was negative except for a few boils on his forearms, pyorrhea alveolaris and an ulcerated throat. There appeared to be a mucopurulent-like membrane covering the back wall of the pharynx, downward and upward, including the soft palate, extending to and overlapping both tonsils. The uvula seemed to be severed in two, the result of the existing ulceration. It looked to me to be one of four conditions, namely, diphtheritic, specific, tubercular, or malignant.

I made smears and cultures to rule out diphtheria, in which I succeeded; those showed no K. L., predominating micrococci catarrhalis, streptococci and staphylococci.

At the same time I took a blood for a Wassermann, which was reported positive.

To the physician it had looked like a tertiary gumma, ruling out tubercular because of its wide distribution with hardly any destruction; and excluding the question of malignancy because of the fact that the patient could freely open his mouth widely with the least bit of pain or disturbance. Dr. Morton Smith advised the administration of antisppecific treatment at once.

I started the patient off with Gr. V of K. L., gradually increasing it to Gr. XV t. i. d. and mercury inunctions. The improvement of the throat was miraculous, even before the administration of arsphenamine.

A week later I started him off with 0.2 mg. of arsphenamine intravenously, increasing the dose to 0.4 mg., which he is receiving every week, at the same time keeping up with the mixed treatment. Later I intend to give him 0.6 mg. of arsphenamine for a few weeks to complete the twelve injections before another blood test.

After an administration of four doses of arsphenamine his throat has cleared up entirely, and he has hardly any discomfort or pain left.

CONCLUSIONS:

One must always guard against specific sore throats, though the patient gives a negative biotic history.

It is important to take a blood test in cases of persisting sore throats accompanied by ulcerations, and which do not clear up under ordinary treatments.

587 Beacon Street.

A CASE OF INTUSSUSCEPTION.

BY PHILIP J. FINNEGAN, M.D., SALEM, MASS.

THE report of this case of intussusception may be of interest on account of the age of the patient and on account of the location of the condition. This girl, 6 years and 7 months of age, was taken sick with a "belly-ache" and cried on Friday morning, the 20th of January, but was sent to school. She seemed to be all right from then until the following night, when she had severe cramps with vomiting, which apparently was faecal, for her mother said it was "stinking." She continued to have these severe cramps and the vomiting until she came to the Victoria Hospital on the evening of the 24th. At that time, she had a temperature of 95.6, pulse of 130, and respirations of 25. From Friday morning she had no bowel movement and passed no blood or mucus; an enema, given shortly after entrance, brought some bloody mucus. Patient was thin and poorly nourished; skin and mucous membranes showed marked pallor; eyes had an anxious expression; tongue was dry and slightly furred with a brownish coat; patient was very restless and in great pain. She was vomiting constantly brownish liquid with a faecal odor, as she had been for three days. Examination of the abdomen showed a long tender mass in the middle of the right side of the abdomen beyond the rectus muscle. This mass appeared to be 8-10 inches long and 3-4 inches wide. Blood pressure: sys., 86; diast., 58.

Operation.—On opening the abdomen by a median incision, there escaped much thin blood-tinged fluid. On the right, a large mass was felt and found to be small intestine greatly adherent and massed together; much fibrin was scattered over the bowels and some bloody fluid was present in the pockets formed by the adherent gut. The caecum was freely movable with a small appendix and was not involved in the condition; the mass was at least eight inches from the ileocecal valve and extended along the ileum for about twelve inches. The distal end of the mass was thick and indurated. The intussusceptum could not be reduced by manipulation and the gut was opened longitudinally and 10-12 inches of bowel the color of chocolate jelly was delivered and resected. A small necrotic sessile tumor, two inches long with a pedicle $\frac{1}{4}$ inch in diameter, and the blunt distal end one inch in diameter, was found in this necrotic gut at the apex of the intussusceptum. A lateral anastomosis was done and one drain placed in the pelvis and another higher up, but avoiding the anastomosis sutures. During the operation, the skin remained warm and her color and respirations were good, with the pulse running between 160 and 170. No stimulants were given; the patient was then put in Fowler's position with Murphy drip.

Following an enema on the next morning, some flatulency was passed, and 36 hours after operation some fluid faeces were passed. From the third day on there were always 4 or 5 involuntary fluid movements, and on the sixth day after operation, there was a formed stool. During this time and for nearly three weeks there was marked distention, which was but little relieved by enemata. There was little if any discharge from the drainage wounds after the removal of the wicks on the fifth day; drains were not replaced. The distention caused the skin edges to gape, but they were pulled together by adhesive plaster. The distention gradually went down, the wound healed, and the girl went home in 5 weeks. For three weeks she had been on house diet and was comfortable except for the distention.

On June the first she is doing well and going to school every day; she eats well, sleeps well, and has had no abdominal discomfort since leaving the hospital.

A TWO-HEADED CALF.

BY EDWARD B. BENEDICT, A.B., BOSTON.

Harvard Medical School.

A TWO-HEADED calf was recently born at the Bothfeld farm in Sherborn, Mass. This calf had a single trunk, and only four legs, but its two spines, though gradually converging, remained separate all the way down and ended in two distinct tails. The two necks converged and joined externally at about the mid-cervical region.

This calf was the fourth offspring of a large pure-bred Holstein cow and bull; the other three calves had been normal. Ordinarily, a calf is born with forelegs first, then head, and finally the rest of the body. In this case delivery was in the following order: right foreleg, right head, left foreleg, left head, then body and hind legs. The delivery was considered a difficult one, as it took three hours, but, curiously enough, it was the delivery of the normal hind quarters that caused the most trouble. The calf did not live, and probably never even breathed, though during delivery of the hind quarters she worked both her tongues around in the manner common to a calf as soon as its head is born.

Examination of the back of the animal showed three separate longitudinal ridges. The lateral ones were due to the spinous processes of the two vertebral columns, and as these processes flared laterally in the thoracic region, there was produced a central 'trough.' This trough was bisected by the median ridge, high in the thoracic region, low in the lumbar area, but traceable to the fused sacra. To make this middle ridge, pairs of short ribs from opposite sides united in the mid-line and sent an undivided process dorsally, thus forming a suc-

cession of spurious arches and spinous processes.

The lateral fore limbs were normal, but the median pair was represented by a broad cartilaginous plate evidently derived from a fusion of two scapulae. This was packed in between the two spines. Deep within the muscles at the root of the neck, and thus at the upper end of the thoracic cavity, there was a spherical cyst, 25 mm. in diameter, thickly lined with white hair. The double scapula and the dermoid cyst were the only indications observed of the median pair of fore limbs.

Internal examination revealed a complete or partial doubling of the respiratory, cardiovascular, and gastrointestinal systems.

The Respiratory System: Two entirely separate systems existed in the single thoracic cavity. A trachea led from each neck down to a pair of lungs on each side. The medial lungs were distinctly smaller than the lateral, and none of the four appeared ever to have been filled with air. This was probably due to the very imperfect development of the diaphragm. In place of a strong tendinous center, it presented two weak membranous layers enclosing between them a very large diaphragmatic hernia.

The Cardiovascular System: There were two hearts of equal size; and cephalad there were two distinct sets of blood-vessels. The arteries appeared to be normal except that the left subclavian of the right animal was suppressed, and the right subclavian of the left animal was abnormally small, save for a branch distributed to the median thoracic region. There were no limbs for these median subclavian vessels to supply. The arches of the two aortae came together in a single descending trunk above the level of the diaphragm.

The Gastrointestinal System: The abdomen of the calf normally is largely filled with the four subdivisions of the stomach. In this instance it was overcrowded with them, for there were seven, owing to the complete doubling of all but the abomasum. That is, the cleavage into two individuals had extended through the rumen, reticulum and psalterium, making two of each, and ended in the fourth stomach, or abomasum, which was only partly subdivided. The oesophagus and first three stomachs on either side were apparently normal, except that the rumen, or paunch, of the right side was in the diaphragmatic hernia. The stomachs of the two sides ended in an abomasum, which was one large lobulated sac, divided superiorly by a median septum. But this septum terminated below, so that there was only a single pylorus. The duodenum and all the intestinal tubes were single and normal, ending in a distended rectum containing abundant hair-filled meconium. The anus was perforate. The urogenital system was unaffected by the cleavage. Since the duodenum was single, those organs which develop from it,

the pancreas and liver, would, naturally, be single; and such was the case. But the liver, with its single gall-bladder, assumed a bilateral disposition across the body, receiving two umbilical veins, and emptying into right and left venae cavae inferiores, passing to the respective hearts. Although there were two stomachs, I

found only one spleen, which was on the left side.

In making this dissection I was assisted by Dr. F. T. Lewis, who expects to publish a note on the embryological significance of the conditions here described.

Unusual Relation of Styloid Processes.

UNUSUAL RELATION OF STYLOID PROCESSES OF RADIUS AND ULNA.

BY G. T. TYLER, JR., F.A.C.S., GREENVILLE, S. C.

During the examination of a patient, I noted that the styloid process of the left radius was about the same level as that of the ulna. Although there was no other abnormality of the fore-arm, I immediately asked the patient when she had broken her arm. When she replied that she had never received an injury, I examined the other arm and noted the same condition. The accompanying x-ray, taken with the hands in pronation, shows the interesting variation. The tip of the left radius lies a little above the plane of that of the ulna. The styloid process of the right is in the same plane as that of the right ulna.

I can give no explanation for this variation; nor have I seen a report of a similar case.

NOTE.

AN unsigned criticism of an advertisement in the JOURNAL has been received. We are always appreciative of constructive criticism, but the general policy of editorial offices is to ignore unsigned communications. A written opinion only carries weight when the author is known.

Usual Relation of Styloid Processes.

Book Reviews.

X-Ray Dosage. By WILLIAM D. WITHERBEE, M. D., Radiotherapist Presbyterian Hospital, New York, and JOHN REMER, M.D., Radiotherapist, New York Hospital, New York. 87 pp. Illustrations 5. The MacMillan Company, New York.

This small monograph is a collection of the previously published papers of the authors.

The first thirty-six pages, about one-half of the book, are devoted to a discussion of the so-called "indirect method" of measuring x-ray dosage and of the formula devised by the authors. No mention is made of the various other methods of measuring dosage. The formula recommended is based on the four fundamental factors—the voltage, milli-ampere, time and distance. The size of the area exposed is not considered.

The technique described by the authors has proved satisfactory in the treatment of superficial lesions where unfiltered radiation was used. When using filtered radiation, it is doubtful if their thesis is correct and it has not been generally adopted.

The latter half of the book describes the method of applying and the dose to be given in infections of the throat, diseases of the skin, uterine fibroids, menorrhagia and Hodgkin's disease. There is also a chapter on the cause and treatment of radio-dermatitis.

The treatment of the various subjects is necessarily brief and somewhat incomplete in a book of this size.

Studies from the Rockefeller Institute for Medical Research. Reprints, Vol. xlii. 1922.

Cowdry makes a plea for conservatism in invention of new terms.

Clark illustrates a device for the measurement of intravenous temperatures.

Stadie illustrates an oxygen chamber for the treatment of pneumonia, and reports a case in which the anoxemia was notably relieved.

Clinical and Operative Gynaecology. By J. M. MUNRO KERR, Professor of Obstetrics and Gynaecology, Glasgow University (Muirhead Chair); Gynaecological Surgeon, Royal Infirmary, Glasgow; Honorary Fellow American Gynaecological Society, etc. London: Henry Frowde and Hodder & Stoughton, the Lancet Building, 1 and 2 Bedford Street, Strand, W. C. 2. 1922.

The author explains in his preface that it has seemed advisable to keep the clinical and operative sections separate. This is a rather

distinct departure from most books of this type, but, because of the excellent drawings furnished by the author and the small descriptive paragraphs accompanying each plate, it would seem that this method has a distinct advantage. One is able to refer to the latter part of the book and find practically all operations briefly described by text and by the excellent outline drawings.

The pathology presented in the book is simply a working pathology suited to the requirements of those interested in the clinical side of gynaecology.

In the operative section, two chapters are devoted to general surgical details and technique. This possibly is unnecessary, as it has been the custom to incorporate such details in practically all surgical books for many years.

There are 31 chapters, most of them short and concise. There are 132 illustrations independent of the outline drawings of operative technique, and a few excellent colored plates. There is one particularly valuable chapter on "Nervous Disorders in Relation to Abdominal and Pelvic Diseases," by Ivy MacKenzie. The volume also contains five pages of outline drawings illustrating various pathological conditions in the pelvis. Such drawings as these we have not yet seen in any of the American textbooks; they are very simple and yet extremely adequate in illustrating the pathological condition which it is wished to describe. For instance, the drawing of an appendix situated in the anterior fornix is a most excellent drawing of an extremely rare condition. Another chapter of note is that on "Disorders of Function."

The book forms a valuable handbook for the busy practitioner or the hospital interne, and might well be used by the medical student.

As a combination of clinical and operative gynaecology the book has decided merit.

Mental Diseases: A Public Health Problem. By JAMES V. MAY, M.D., Superintendent, Boston State Hospital; Chairman Committee on Statistics, American Psychiatric Association; formerly member New York State Hospital Commission, etc. With a Preface by Thomas W. Salmon, M.D., Professor of Psychiatry, Columbia University, New York. 536 pages. Boston: Richard G. Badger. 1922.

This volume is in one respect unique among works on mental diseases, presenting, as it does, as a distinguishing feature, the statistical aspect of the subject. Under this head the author has brought together an array of heretofore scattered facts and figures, which, although they are in the main familiar to the psychiatrist, should impress thinking people generally and be especially helpful in the education of a public at last awakening to an adequate realization

of mental disease both as a far-reaching malady and a social and economic burden.

The parent, physician, clergyman, educator and sociologist alike can find here an ample supply of statistical data to fortify their views on the subject of the mental health of the community and the pitfalls that threaten it. In this connection it perhaps would have been well if something more than indirect reference had been made to the question whether or not mental disease is increasing, a point on which there is very general interest and, in spite of enlightening research, much popular misinformation.

Among General Considerations are the mental hygiene movement, immigration and mental disease, and endocrinology and psychiatry—subjects which do not often find prominent places in books on psychiatry. The psychiatry of the war is also given a brief but satisfactory résumé.

The latter half of the work is devoted to descriptions of the individual psychoses. The author has admittedly confined himself to reflecting the views of others, throughout the book using actual quotations from recognized authorities. Nevertheless the compilation of these chapters is so thorough, embracing, as it does, the development of each disease form according to the conceptions of different observers, as to make them especially valuable for reference purposes.

A Text-Book on Gonorrhoea and Its Complications. By DR. GEORGES LUYs. Translated and Edited by ARTHUR FOERSTER. 3rd Revised Edition. William Wood & Co. 400 pages. 212 Illustrations and 5 Colored Plates. Price \$6.50.

This book is one of the most fascinating treatises on gonorrhoea which the reviewer has seen. Its outstanding feature is the thoroughness with which the author goes into the various aspects of this disease. The history and pathology of this infection are unusually good. Luy's is an advocate of urethroscopy, a procedure which he apparently employs a great deal more than do most urologists in this country. He gives numerous illustrations, both in black and white and in colors, of the conditions which he has found. One feels that he is a past master of all the more delicate and expert intraurethral manipulations; he has something to say, either pro or con, in regard to the more unusual methods of treatment, such as the application of heat, ionization, and electrolysis.

The question might be raised as to the wisdom of so much manipulation as Luy's advocates. He states that the incidence of epididymitis is 25 per cent., a figure which seems to us to be shockingly high. It may be that this high percentage is caused by too extensive intraurethral treatment.

Luy's style is interesting, and is made more so

by the numerous résumés of cases, recited, with many a Gallic touch, as a bit of intimate gossip. His translator seems to have preserved this characteristic of the book very well, and except for a few passages in which he has been careless about his English, has done an excellent piece of work.

It would be beneficial to many American urologists to read this book.

The Psychic Health of Jesus. By WALTER E. BUNDY, Ph.D. Pp. 299. New York: The Macmillan Co. 1922.

This volume can be discussed from two aspects, the theological and the psychopathological and psychiatric, but only the latter will be touched upon here. According to the author, the latter fields are entered into only so far as the contentions against Jesus' psychic health have forced the problem, and then only in its relation to the New Testament sources.

The book discusses in detail, the various psychiatric and pathographic accounts of the personality of Jesus, as to whether or not he was an ecstatic, an epileptic, a paranoiac or a neurotic. Such a discussion may be of value, but when any great leader in the world's history of thought or action is submitted to a psychiatric analysis, there can nearly always be found personality traits which can be easily labelled with a scientific terminology. Such labelling, however, can neither adequately express the greatness of the man nor detract one iota from his contribution to human thought, for all great men have something within them which deviates from the normal, and it is probably this very deviation which renders them great and makes them impatient and intolerant of the religious, scientific, social or literary trends of the age in which they lived. All great men possess to a higher degree than their ordinary fellow men, a creative imagination which manifests itself in that symbolic thinking which illuminates the reality of things in genuine truth and inspiration, so that their contributions become the common heritage of mankind.

It would seem that this attitude is in agreement with Dr. Bundy's summing up of the situation, for he states that the pathographers of Jesus "have toyed wantonly and wilfully with the figure in history to which are attached the sincerest sentiments and the dearest affections of the occidental religious world, and without sufficient reason or justification."

The book contains a few errors of psychiatric terminology, such as the use of the word "hallucinations" instead of "delusions," while the translation of the French word "*délire*" is rendered "delirium." According to the bibliography, the author has overlooked Berguer's contribution to the life and personality of Jesus from the psychoanalytic standpoint published in 1920.

Miscellany.**OFFICIAL BULLETIN OF THE AMERICAN COLLEGE OF SURGEONS.**

Boston, October 23.—Hospital service to the public in Massachusetts has shown a marked advance in the past year, according to the fourth annual report of the American College of Surgeons, released here today. This report is based on a survey which includes personal visits to each hospital of fifty beds or over in the United States and Canada. The attached list of hospitals was given a place on the "approved" list.

The asterisk indicates hospitals which have instituted measures which insure scientific medical care to their patients, but which have not realized them to the fullest extent to date.

"The institutions listed proved that they are giving the best of scientific care to their patients," declared Dr. Franklin H. Martin, Director-General of the American College of Surgeons. "Aided by one of the great educational foundations, we have carried on actual visits to hospitals, made by trained medical men who see working conditions as they are. For the first time this year we have surveyed hospitals of 50-bed capacity and up. These institutions, as well as the larger hospitals, show a marked improvement the country over and place Massachusetts in the fore-front of States which are active in medical progress. Massachusetts is to be congratulated on its splendid showing and on the medical men, hospital superintendents, and trustees who have made this advance possible."

AMERICAN RELIEF ADMINISTRATION.

Moscow, September —Can an anti-typhus serum be discovered in time to check what promises to be one of the worst epidemics of this disease to which Russia has ever been subjected?

In the laboratory of Sakalitchsky Epidemic Hospital here Dr. N. Kritch, a woman physician, and Dr. V. Barikan, director of the Moscow Micrological Institute, are working unrelentingly in the hope that they can develop the required anti-bodies to combat the Microbion Typhi Exanthematici which they discovered last spring after six years' work on the etiology of typhus, before winter increases the already high incidence of the disease. Upon the success of their efforts may depend the lives of hundreds of thousands, if not millions, of typhus victims within the coming six months.

For the typhus is not only disseminated throughout Russia to an extent hitherto unknown, but the typhus curve, which usually falls in summer until deaths from the disease are of rare occurrence, and rises in the winter, when lack of bathing facilities and the use of added clothing tends to increase the vermin infestation, has not pursued its usual course. Instead of falling during the summer months it has remained practically level. Last winter the incidence of the disease was abnormally high even for Russia. This summer it has remained high, indicating, in the opinion of both Russian and American physicians who have studied the situation, that the epidemic this winter will be even more severe than that of last year.

In order that they may pursue their researches the American Relief Administration has provided the laboratory where their experiments are being carried on with all the necessary supplies for their work, and in addition has given food packages to the experimenters.

AMERICAN SYNTHETICS.

The Fordney-McCumber Tariff Bill, recently passed by Congress, unfortunately does not provide sufficient protection for American-made medicinal chemicals, nor does it compensate for the extensive research work which has been done by American chemists.

The rates on medicinal chemicals were passed over the protest of the medical profession. It is now possible for the physicians to follow up their protests by using only American-made synthetics, and referring to them at all times by their American names, as suggested by the Council on Pharmacy and Chemistry of the American Medical Association.

Among the important American-made medicinal which should receive the support of all American physicians, are Arsphenamine, Barbitol, Cinchophen and Procaine.

RÉSUMÉ OF COMMUNICABLE DISEASES.

SEPTEMBER, 1922.

General Prevalence.—There was a general increase in the more prevalent communicable diseases for the month. Diseases showing an increase for the month are anterior poliomyelitis, diphtheria, ophthalmia neonatorum, scarlet fever, typhoid fever and whooping cough. Anterior poliomyelitis was reported in 63 cases, against 55 for last month, and 54 for September, 1921. Diphtheria was reported in 578 cases for the month, 481 for August, 1922, and 525 for September, 1921. Ophthalmia neonatorum was reported in 109 cases, against 100 for the previous month. There were 149 cases reported in September, 1921. Scarlet fever was reported in 281 cases, against 208 for the previous month, and 279 for September, 1921. Typhoid fever was reported in 131 cases, against 101 for the previous month, and 124 for September, 1921. Whooping cough was reported in 637 cases, against 483 for the previous month, and 247 for September, 1921.

Chicken-pox was reported in 53 cases, against 60 for the previous month, 61 for September, 1921.

Measles.—During the month 269 cases were reported, against 338 for the previous month, 201 for September, 1921.

Pneumonia, Lobar.—There were 86 cases reported for the month, against 91 for August and 126 for September, 1921.

Tuberculosis, Pulmonary, was reported in 457 cases for the month, against 547 for the previous month, and 512 for September, 1921.

Gonorrhea was reported in 493 cases and *syphilis* in 179 cases.

RARE DISEASES.

Anterior poliomyelitis was reported from Abington, 1; Attleboro, 3; Belmont, 1; Boston, 15; Brockton, 1; Brookline, 1; Cambridge, 2; Clinton, 1; Danvers, 1; Dennis, 1; Eastham, 1; Fall River, 2; Gloucester, 1; Greenfield, 1; Hanover, 1; Lawrence, 2; Lynn, 1; Lynnfield, 1; Malden, 1; Manchester, 1; Marblehead, 1; Medford, 2; Natick, 3; Needham, 1; New Bedford, 2; Northbridge, 1; Peabody, 1; Quincy, 1; Revere, 1; Somerville, 2; Webster, 2; Wellesley, 1; Westport, 1; W. Springfield, 1; Woburn, 2; Worcester, 1; Wrentham, 1; total, 63.

Dog-bite requiring anti-rabic treatment was reported from Billerica, 1; Boston, 3; Chelmsford, 1; Dartmouth, 1; Fall River, 1; Holyoke, 1; Lowell, 8; Warren, 1; Winthrop, 4; total, 21.

Dysentery was reported from Boston, 1.

Encephalitis lethargica was reported from Arlington, 1; Ayer, 1; Boston, 1; Brockton, 1; Lynn, 1; Melrose, 1; Quincy, 1; Taunton, 1; Watertown, 1; total, 9.

Epidemic cerebrospinal meningitis was reported from Boston, 1; Lancaster, 1; Lawrence, 1; Peabody, 1; total, 4.

Hookworm was reported from Boston, 5.

Leprosy was reported from Cambridge, 1.

Malaria was reported from Boston, 2; Hadley, 2; Lowell, 1; Newburyport, 1; Uxbridge, 2; total, 8.

Pellagra was reported from Boston, 2.

Septic sore throat was reported from Boston, 1; Holyoke, 1; total, 2.

Tetanus was reported from Boston, 2; Brockton, 1; Sandwich, 1; Sterling, 1; total, 5.

Trachoma was reported from Acton, 1; Billerica, 1; Boston, 4; Cambridge, 1; Worcester, 1; total, 8.

Trichinosis was reported from Boston, 1.

CENSORS' MEETING.

The Censors for the several districts will meet for the examination of applicants for fellowship on the first Thursday of November.

The Censors for the Suffolk District will examine applicants residing in that district and also applicants who are non-residents of Massachusetts.

Applicants for fellowship should apply to the Secretary of the District Society of the district in which they reside (have a legal residence) at least one week before the date of a given examination, taking with them their degrees in medicine.

"TIMEO DANAOS ET DONA FERENTES."

Among the various circulars, samples, blotters, and calendars which constitute so large a proportion of every doctor's mail, there recently appeared a 12-page pamphlet entitled "Proprietary Medicines and the Doctor." This treatise was written by Judge Irwin G. Jennings, M.A., Ph.D., who is apparently the Lord High Director of Diplomacy for the Glass Container Association.

Judge Jennings' article is an appeal to the medical profession to co-operate with the proprietary medicine manufacturers. The writer argues that there is no ground for the doctor's hostility towards patent medicines; that the latter no longer contain narcotics or alcohol. He neglects to say that the chief reason they do not contain these, is that the A. M. A. brought about the passage of the Pure Food and Drug Act in order to stop the indiscriminate sale of poisons to the ignorant and the credulous. Proprietary medicines, says Jennings, are more accurately compounded and are cheaper than the same formulae when made up according to a physician's prescription. Their relative cheapness, he continues, enables the poor to have medicine even if they cannot afford a doctor and keeps them from the faker and the quack. (In our experience these two last named gentlemen have no use for the poor anyway.)

Judge Jennings devotes several pages to figures culled from various reports, to prove that many people cannot afford to pay a doctor. No doctor needs proof of this—his own accounts are evidence enough. Jennings' greatest argument for co-operation is based upon his premise that the practice of legitimate medicine is about to go to the wall through the activities of Osteopaths, Chiropractors, et al. If the doctor will only let the manufacturers of proprietary medicine have a free hand, the latter "can easily keep the American public sold to the curative properties of drugs," and by so doing, will force them back into the arms of Regular Medicine.

This ingenuous attempt to persuade the medical profession to be the publicity agent for the proprietary medicine companies is too weak to stand alone. It falls to pieces as you examine it. In the first place, the function of the doctor is not to sell medicine or to prescribe it. His function is to diagnose disease, and, having done so, to take steps to relieve its symptoms or to eradicate its cause. In the accomplishment of these ends, the administration of medicine plays but a small part. The drugs which are of value are few in number and are best given in their simplest and least complicated forms. Narcotics cannot be dispensed except by special prescription. Specific remedies such as quinine in malaria and mercury in syphilis should not be taken unless the disease has first been accurately diagnosed. Cardiac tonics and diuretics should be given only in well-regulated doses under the doctor's guidance. Judge Jennings says that inasmuch as the great majority of human ills are of a general make-up, such remedies, i.e., prescriptions of a general nature, are appropriate and valuable for the purpose. We do not know what he means by this unless it is that the use of the shotgun prescription once so popular but now regarded as poor medicine, is the most economical way of preserving the health. Even those favorites of the patent medicine man, the cough mixtures and the tonics, should not be consumed indiscriminately.

In fact the entire theory of self-diagnosis or of drug clerks' diagnosis, upon one or the other of which the use of patent medicines depends, is most pernicious, and is likely to lead to the neglect of symptoms which are in reality signals of danger ahead. Even if we assume that the proprietary medicines are cheaper than similar formulae privately compounded we cannot regard them as cheaper in the long run. For one thing their composition is unnecessarily complex. If a definite therapeutic effect is desired, it can be secured best by the use of the simple drug and not by the use of a compound in which the action of various substances tend to obscure one another. The poor can get help in hospitals. Even if they do not avail themselves of this opportunity, they would do much better to in-

vest five dollars in one visit to a competent physician than to spend the same amount or probably much more in self-directed experimentation in pharmacology as contained in the patent medicine bottle.

The time has come when as a result of persistent attempts at education, the more intelligent portion of the public has learned to keep away from patent medicine. It would seem as if the vested interests realize the menace which education holds for their business and hope by such efforts as this one of Judge Jennings to regain their grip upon the imagination of the public. If they expect the medical profession to aid them, they are doomed to disappointment.

THE COLLEGE OF SURGEONS—AND BOSTON.

A GLANCE at the programme extraordinary prepared for the visiting surgeons of the present week arouses feelings of amazement, not entirely unminged with consternation. Apparently every single hour from 9.30 Monday morning to 11.30 Friday night is crammed to overflowing with clinics and conferences, lectures, demonstrations, operations, end-results, registrations and convocations; there are a few brief and fleeting moments left for food and sleep, but for human contact of man to man,—for short intervals during which visitors might glance, if ever so briefly, at many things in Boston, historie, picturesque and more or less medical, there seems to be neither time nor provision. This is, to say the least, unfortunate. But let us hasten to observe that it in no way reflects on Boston hosts, or the physicians of the Hub. It is precisely in the spirit and practice of well nigh all medical meetings in the United States—and based upon the theory that a moment left without formal medical exercises of one or another variety is a moment hopelessly lost.

This view, however, is not held throughout other parts of the world; particularly in Canada, the British Isles, and Central Europe. There the great medical meetings take cognizance of the fact that all work and no play is even worse for adults than for children; there they realize the great and simple truth that the most important element in medical meetings is, literally, in meeting, and talking with, medical men. In direct personal conversation and entirely informal exchange of views, more may often be learned than in listening to lectures, or even attending clinics. This personal contact is both a pleasure and a privilege, and often an inspiration. More time should be permitted for it, and assigned to it. Moreover, the cities in which the annual convocation of the College are held, contain, without exception, features of very great interest to medical men and their families.

In Boston, for example, naming at random

a few of very many things which have, at least remotely, medical aspects, there is:

The Metropolitan Park System—one of the first and finest in the world, of very great importance in relation to the health of the community; a system easily visited, and dotted with memorials of special interest to doctors. One thinks immediately of the Ether Monument, which always brings to mind the well-worn pun: the exedra and sundial upon the Charles River Esplanade, directly in the rear of 298 Beacon Street, bearing the dedication to the poet whose library overlooked it—and the lines from one of his most graceful songs:

"Love dies not when he bows his head
To pass beneath these darkened Portals."

And speaking of Dr. Oliver Wendell Holmes, let it not be forgotten that the actual physical inspiration which resulted in the most beautiful of his verses, the shell which caused him to sing of "The Chambered Nautilus," rests in a cabinet in the Boston Medical Library, in the hall so appropriately named for him.

Adjoining it, in Holmes Hall, is the unique collection of medals acquired by the late Dr. Horatio Storer, who died only a few days ago at Newport. Dr. Storer was at once Harvard's oldest living graduate and one of America's greatest physicians. This collection is by far the most important and the largest in the world, and has been catalogued and arranged by Dr. Malcolm Storer, who, like his father, is an eminent numismatologist.

In the park surrounding Bunker Hill Monument stands the simple granite stone which marks the spot where General Joseph Warren fell—a skilful physician whose name has for 150 years been held highly by five generations of medical men.

Where but in Boston could a doctor say to a companion: "Do you see that gentleman across the street? I cut that man; my father cut his father; my grandfather cut his grandfather"!

How many Bostonians or visitors, as they leave the South Station, realize that the spot from which the "Indians" embarked for the greatest of all afternoon teas is diagonally across Atlantic Avenue on the corner of Pearl Street, and properly marked by tablet and verse? It is credibly believed that among those Boston Indians at least one Boston surgeon brandished, not inappropriately, a knife, and perhaps a tomahawk. How many remember, by walking further along the avenue, one may stand on the very spot upon which the undefeated frigate, the Constitution, was built and launched, and from which she set sail; and that looking north-west by north from this spot we still may see the frigate herself—with lofty mast, and powerful spars, just as in 1813, lying quietly at the Navy Yard in Charlestown?

Perhaps it may be a trifle lacking in humor to call the attention of surgeons to graveyards—

but graveyards are parks and precious spots in Boston, and of interest to everyone who reveres the worthy dead. A visit to Copp's Hill burying ground, above the picturesque granite terrace almost opposite Constitution Wharf, becomes a visit of very great interest, both for what may be seen in the yard and for what may be seen from it; it is literally on a hilltop. And in the Old Granary graveyard the surgeon may see the gravestone of Dr. John Jeffries, of gentle memory, next to that of his townsman, Paul Revere, and close to the granite pyramid which the youngest son, Benjamin, raised to his parents, the elder Franklins, and upon which he caused to be placed so admirable an epitaph.

And if the visitors will stray as far afield as Cambridge they may well go "for to admire and for to see" that really beautiful burying ground at Mount Auburn, which was conceived and planned and made possible by Boston's greatest surgeon; in whose name the great golden medal was last night so appropriately bestowed upon his friend, another great American surgeon—Bigelow and Keen, great men, as well as great doctors.

Of course, every visitor should go and worship in the old amphitheatre, high in the rounded dome of the Bulfinch Building at the Massachusetts General Hospital—and gaze reverently about him, upon the room which looks now just as it did on the day when within its walls general anesthesia was first given by American doctors to a suffering world. And they may also look with great interest at the small tablet over the narrow door on Tremont Street, near Pemberton Square, which marks the building in which nitrous oxide gas was first deliberately administered in operative dentistry.

Coming down Tremont Street, let them turn into West and thence to Mason, and glance at the first building ever erected for the Harvard Medical School; a substantial brick structure in which the original lines may still be discerned, notwithstanding that Boston has taken the building and so changed it that it has become as good a fire engine station as it once was a medical school—and for both one of the best in the country.

On Washington Street, opposite Boylston, there stands at present a substantial store within which excellent rugs and carpets may be purchased. Years ago and for many years, good Bostonians purchased equally excellent pastry at this spot: it is also written that the original proprietor and his nephew increased their profits by cutting their pies into *five* quarters, instead of into four; and they still gave more, and better, at the old tariff, than can now be obtained for three times as much: from this simple and apparently unimportant episode—and due largely to it—came two great hospitals to Boston; and to Boston now come medical men from the ends of the earth, to see the work which is done in these institutions. Truly some

substantial gains accrue to those who live in the Great Pie Belt!

Every surgeon coming to Boston should see the Crow Bar, and the Crow Bar Skull, as well as the rest of the great collection in the Warren Museum, three flights up in the Administration Building of the Harvard Medical School; and stand before the case which contains the skeleton of a benefactor of the museum, which, by the provisions of his will, is annually visited and inspected by grave and reverend seniors. Incidentally, if he goes to that school as he should, on foot up through Avenue Louis Pasteur, he may look upon public schools, palaces, academies, hospitals large and small, and many great white laboratories, as many and as fine as may be found in all the world—a singular contrast, indeed, to the old brick fire station in Mason Street.

This list might be extended obviously and indefinitely; no attempt is made to do more than suggest a very small part of the objects and places that might be visited by those interested. Of course, the Public Library and Art Museum may be taken for granted. But none of these things can be done without time—and no time is allowed by the programme; nor, indeed, are such medical and pious pilgrimages even suggested.

Let it be remembered also that the other cities in which the Congress has held convocation, and will yet hold them, have spots and objects equally interesting as those in Boston. New York, Philadelphia, Baltimore, Washington, Chicago and many other places are rich in matters often essentially medical, sometimes partly so and occasionally not at all surgically related, but well worth visit and contemplation by any man who holds the highest ideal of the physician before him as his model.

Would it not be possible to begin clinics at 8.30 A. M., carry them on until 12.30 P. M., begin again at 1 and end at 3 P. M., and then let the doctors, their wives and their friends take a few long breaths of fresh air, and look at some of the other things that make life so well worth living in Boston, and in America?

News Notes.

TUFTS COLLEGE MEDICAL AND DENTAL SCHOOLS.—Medical Registration for the Session of 1922-1923: 1st year, 145; 2nd year, 127; 3rd year, 144; 4th year, 61. Pre-Medical Registration: 1st year, 179; 2nd year, 107. Dental Registration for the Session of 1922-1923: 1st year, 42; 2nd year, 46; 3rd year, 156; 4th year, 127. Pre-Dental Registration: One year, 128.

Dr. Andrew W. Ryan, who has been for several years engaged in industrial research in physiology, has returned to active teaching as Professor of Physiology.

Dr. Benjamin Spector, Assistant Professor of

Anatomy, comes to Tufts from Cornell Medical School, where he taught last year.

DEATH RATE IN BOSTON.—During the week ending October 21, 1922, the number of deaths reported was 204, against 173 last year, with a rate of 13.93. There were 36 deaths under one year of age, against 21 last year. The number of cases of principal reportable diseases were: Diphtheria, 62; Scarlet Fever, 23; Measles, 25; Whooping Cough, 30; Typhoid Fever, 4; Tuberculosis, 45. Included in the above, were the following cases of non-residents: Diphtheria, 12; Scarlet Fever, 6; Typhoid Fever, 3; Tuberculosis, 5. Total deaths from these diseases were: Diphtheria, 4; Tuberculosis, 11. Included in the above, were the following cases of non-residents: Diphtheria, 1; Tuberculosis, 2.

BEVERLY HOSPITAL.—The following is the program of the demonstration clinic held at the Beverly Hospital October 17th:

Fistula in ano. Tumor of the abdomen. Pneumonia. Pneumonia. Fever unexplained. Acute gangrenous cholecystitis. Acute hemorrhagic pancreatitis.

THE JOINT MEETING AT TEWKSBURY.—A joint meeting of Middlesex North, Middlesex East, Essex North and South was held at the State Institution, Tewksbury, on Wednesday, Oct. 18, 1922, with about 200 members in attendance. The visiting members were received by the Superintendent, Dr. John Holyoke Nichols, who, with his corps of assistants, conducted the party in groups about the institution. At 3:30 P. M. all gathered in the chapel, where the meeting was held.

Dr. J. W. Bartol, the President of the parent society, spoke of the reciprocal relation of the society and the individual component units and asked that suggestions be made to the Council as to the various activities of the society. Dr. C. F. Painter discussed some of the problems connected with the duties of the Board of Registration in Medicine and referred to some recently attempted legislation in this connection.

Dr. James S. Stone presented for the consideration of the members several alternative propositions for dealing with the situation arising as a result of complaints concerning certain of the smaller hospitals which have been housing obstetric cases and others which have had the care of insane persons.

Dr. Henry Jackson delivered an address upon Diseases of the Myocardium, illustrating the value of the polygraph and electrocardiograph in diagnosis and prognosis.

Dr. J. H. Nichols gave some interesting and instructive statistics of the infirmary covering his thirty years' connection with the institution.

It was voted unanimously that a similar joint meeting should be an annual feature of the program of the four district societies represented.

Mr. Conant, chairman of the Commissioners of Public Welfare, welcomed the society and voiced a tribute to the efficiency and enthusiasm of the Superintendent, Dr. Nichols.

Dr. Anthony, one of the trustees, spoke of the quality and great variety of professional work accomplished at Tewksbury.

A vote of thanks was extended to the speakers of the afternoon and to Dr. Nichols for his hospitality.

Adjournment at 5:30 was followed by an excellent dinner. William H. Hopkins, M.D.,

Reporter.

BERKSHIRE DISTRICT MEDICAL SOCIETY.—A meeting of the Berkshire District Medical Society was held at the Richmond Hotel, North Adams, on Thursday evening, October 26th, 1922. Dr. Charles M. Williams, Professor of Diseases of the Skin at the Post Graduate Medical School of New York City, gave a practical talk on the diagnosis and treatment of the more common diseases of the skin, with illustrations.

AT THE MEETING OF THE AMERICAN COLLEGE OF SURGEONS Dr. I. S. F. Dodd, Dr. J. B. Thomas, Dr. B. W. Paddock and Dr. T. P. Hennessey were initiated as Fellows of the College, all residents of Pittsfield.

Directly following this meeting Dr. Thomas and his wife went to Maine, where they will remain for about a month.

The wife of Dr. Louis Barnes of Lanesborough is confined to the House of Mercy Hospital in Pittsfield, following an operation recently performed.

Dr. John J. Boland of Pittsfield has returned to his practice after a visit to New York clinics.

THE MEETING OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.—At the meeting of the Suffolk District Medical Society on Wednesday evening, October 18, an enthusiastic audience, which filled Ware Hall, greeted Dr. John O. Polak, professor of obstetrics in the Long Island College Hospital.

Dr. Polak stated that the title of his address should in reality be "A Plea for Safe Obstetrics." He pointed out the relatively small number of operations in obstetrics which were necessary in a large obstetric service such as he conducts, and he showed that the number of Caesarean sections which he found necessary corresponded very closely with those found necessary in the Johns Hopkins Hospital; about one in 120 cases. He then pointed out the absolute and relative indications for Caesarean section and finally emphasized that there is today too much operating in obstetrics; that Caesarean section is not safe; that unnecessary operations are done, and that, all in all, both the morbidity

and mortality are much higher than in regular abdominal sections; and that, furthermore, Caesarean sections are by no means devoid of risk to the child.

The paper was discussed by Dr. Newell, Dr. DeNormandie, Dr. Ruggles, Dr. Friedman, Dr. Mongan and Dr. Donoghue.

Dr. Donoghue very pertinently pointed out that outside of the large cities there is a scarcity of men trained in obstetric work, and that therefore surgeons were called in who did Caesarean sections where trained obstetricians might deliver by other methods. Dr. Mongan made an earnest plea for the coöperation of all members of the Society with the new Section on Obstetrics in the Massachusetts Medical Society.

THE BOSTON DISPENSARY.—The October meeting of the Medical Staff of the Boston Dispensary was held on Wednesday, October 11th, in the rooms of the Medical Department. Dr. William E. Preble, Physician-in-Chief of the Medical Department, read a paper, "Observations on 1,000 Cases of Obesity," 700 of which were taken from his own records, and 300 from the records of the Boston Dispensary. Charts showing the incidence of high blood pressure, diabetes, nephritis, heart disease, and other conditions, among these 1,000 cases, were also shown.

HARVARD MEDICAL SCHOOL.

At a meeting of the President and Fellows of Harvard College in Boston, October 9, 1922, it was voted to appoint them: Abbott Lawrence of the Boylston Medical Committee:

Dr. Reid Hunt, Secretary, Drs. William T. Porter, Robert W. Lovett, Henry A. Christian, John Warren and Henry Lyman.

The resignation of Lawrence Weld Smith as Instructor in Pathology was received and accepted, to take effect September 1, 1922.

The President nominated the following persons as members of the Administrative Board of the Medical School for the year 1922-23, and it was voted to appoint them: Abbott Lawrence Lowell, ex-officio; David Linn Edsall, ex-officio, Chairman; Algernon Coolidge, Milton Joseph Rosenau, Harvey Cushing, Reid Hunt, John Lewis Bremer, Walter Bradford Cannon, Charles Macfie Campbell, Worth Hale, Simeon Burt Wolfbach, Oscar Menderson Schloss, Francis Weld Peabody.

(Consented to by the Board of Overseers at their meeting of October 9, 1922.)

Voted to make the following appointments for one year from September 1, 1922: *Instructors*—Zabdiel Boylston Adams in Orthopedic Surgery, Henry Ingersoll Bowditch in Pediatrics, Lloyd Thornton Brown in Orthopedic

Surgery, Michael Joseph Couroy in Pathology, Louis Riley Daniels in The Practice of Industrial Medicine, Henry Joseph FitzSimmons in Orthopedic Surgery, Otto John Hermann in Surgery, Daniel Fiske Jones in Surgery, Arthur Thornton Legg in Orthopedic Surgery, Halsey Beach Loder in Surgery, Richard Henry Miller in Surgery, Frank Roberts Ober in Orthopedic Surgery, Channing Chamberlain Simmons in Surgery, Marius Nygaard Smith-Petersen in Orthopedic Surgery, Robert Soutter in Orthopedic Surgery, Philip Haskell Sylvester in Pediatrics, Wyman Whittemore in Surgery, Edward Theodore Wyman in Pediatrics.

Assistants.—Percival Bailey in Surgery, William Bradley Breed in Medicine, Albert Howell Brewster in Orthopedic Surgery, Trevor Goff Browne in Pathology, Thomas Ellwood Buckman in Pediatrics, Edward Delos Churchill in Surgery, Bronson Crothers in Pediatrics, Robert Dudley Curtis in Pediatrics, Robert Ogden Dubois in Pediatrics, Paul Waldo Emerson in Pediatrics, Martin Joseph English in Pediatrics, Richard Spelman Eustis in Pediatrics, Ralph Ghormley in Orthopedic Surgery, Frederic Leo Good in Gynecology, Hyman Green in Pediatrics, Francis Browne Grinnell in Bacteriology and Pediatrics, Louis Webb Hill in Pediatrics, Harold Valmore Hyde in Anatomy, Henry Jackson, Jr., in Medicine, Carl Edward Johnson in Comparative Anatomy, Robert Joseph Kirkwood in Pathology, Arthur Bates Lyon in Pediatrics, Arthur Rolan Newsum in Pediatrics, Derric Choate Parmenter in Industrial Medicine, Monroe Jacob Schlesinger in Pathology, Warren Richard Sisson in Pediatrics, Harold Wentworth Stevens in Industrial Medicine, Harry Weiss in Bacteriology, Philip Duncan Wilson in Orthopedic Surgery.

William Charles Boeck, Research Fellow in Comparative Pathology; Selig Hecht, Research Fellow in Physical Chemistry; Charles Carroll Lund, Alumni Assistant in Surgery; Joseph William Schereschewsky, Associate in Preventive Medicine and Hygiene; William Justus Merle Scott, Arthur Tracy Cabot Fellow in charge of Laboratory of Surgical Research.

At a meeting of the President and Fellows of Harvard College in Cambridge, June 21, 1922, it was voted to proceed to the election of a Professor of Orthopedic Surgery, to serve from September 1, 1922: Whereupon, ballots being given in, it appeared that Robert Bayley Osgood was elected.

This election carries with it the position as chief of the orthopedic service at the Boston Children's Hospital. Dr. Osgood has, accordingly, been appointed visiting surgeon and head of the orthopedic service at the Children's Hospital in place of Dr. R. W. Lovett, whose resignation has been accepted. Dr. Osgood will assume his new duties at once.

THE BESTOWAL OF THE HENRY J. BIGELOW MEDAL TO DR. KEEN.

A SIMPLE recital of the exercises in Jordan Hall on the evening of October twenty-fifth, even with the copy of Dr. William Williams Keen's address, as published in the JOURNAL of October twenty-sixth, can never convey to those not privileged to be present an adequate appreciation of the dignity of that occasion. The graceful introduction by Dr. Robert W. Lovett, followed by the address of Dr. Keen, delivered with enthusiasm which would have been remarkable in a much younger man, thrilled the audience.

The introduction and the address were recorded in the pages of a previous issue of this JOURNAL, and in completion of the program we now have the honor of publishing the presentation speech of Dr. Harvey Cushing, which will stand as a fitting tribute to the preëminent standing of Dr. Keen as a surgeon, and a gentleman whose life has been devoted to humanity.

(Dr. Cushing's Speech)

DR. KEEN: From time to time, to an individual, "for conspicuous contributions to the advancement of surgery," the Boston Surgical Society awards a gold medal bearing the name and presentment of a man once a great figure in our profession.

This Society has decided on this occasion to make its award not to an individual but to an institution incorporated with unbounded enthusiasm over half a century ago.

The institution to which I refer has been distinguished from the outset for its patriotism; and its first official act as long ago as 1861 was the loan to the Fifth Massachusetts Regiment, and so to the Nation, of an assistant surgeon.

Soon after it came into existence, the same institution established an editorial and publishing bureau, and since the first appearance in print in 1864 of a medical classic entitled "Gun-shot Wounds and Other Injuries of the Nerves," there has followed a series of essays, monographs and volumes of no less interest and importance.

It has given to the profession a succession of teachers in anatomy and surgery in more than one school of medicine—demonstrators, lecturers, professors, and even a professor emeritus—so that its pupils have been legion.

When that most unpromising of all specialties, the surgery of the nervous system, needed an optimistic pioneer, it was called upon to furnish one.

It has provided a most active and courageous champion against the opponents and slanderers of the experimental method in the medical sciences.

It has also provided a series of Fellows, of Trustees, even of Presidents for many scientific, learned and professional bodies at home and abroad—one of them a society founded by our common, though not quite contemporary fellow townsman, the equally many-sided Benjamin Franklin.

It was once said by Horace Greeley that "fame is a vapor, popularity an accident, riches take wings, those who cheer today will curse tomorrow; only one thing endures, and that is character."

Accordingly to you, Sir, to you as an American institution, to you who already stand knee-deep in honors, in all affection and with all humbleness, in the name of the Boston Surgical Society, and by its direction, I present still another award, the Henry Jacob Bigelow Medal, highly deserved not only for your accomplishments and services to medicine, but for that which means more than these—for that more enduring quality—your professional character.

Dr. Keen then thanked the Society for the honor conferred. Dr. Lovett then closed the meeting.

PROGRAMS FOR HOSPITAL CLINICS DURING
CANCER WEEK, NOV. 12 TO 18, 1922.

CARNEY HOSPITAL.

Monday, November 13, 1922.
9:30 A. M.

Gynecological Operations and Demonstrations of End-Results: Dr. P. W. Johnson and Dr. L. E. Phaneuf.

Surgical Operations and Demonstrations of End-Results: Dr. J. T. Bottomley, Dr. D. F. Mahoney and Dr. A. McK. Fraser.

THE PETER BENT BRIGHAM HOSPITAL.

AMPHITHEATRE, OPERATING BUILDING,
10 A. M. to 12 M.,

Tuesday, November 14, 1922.

The Pathology of Malignant Disease in Relation to Age: Dr. Wolbach.

The Treatment of Malignant Disease of the Prostate and Bladder: Dr. Quinby.

Malignant Disease of the Central Nervous System: Dr. Cushing.

Symptomatology of Cancer of the Alimentary Tract and Its Operability: Mouth to Pylorus: Dr. Cheever. Large Intestine and Rectum: Dr. Homans.

Recent Advances in the X-Ray Treatment of Malignant Disease: Dr. Sosman.

OPERATIVE CLINIC DURING THE MORNING.

COLLIS P. HUNTINGTON MEMORIAL HOSPITAL.

Tuesday, November 13, 1922,
2:30 P. M.

The Cancer Commission of Harvard University.
Dr. R. B. Greenough.

Radium in the Treatment of Disease,
Dr. William Duane,
Cancer of the Skin,
Dr. L. S. McKittick.

The State Free Diagnosis Service,
Dr. J. H. Wright.

Cancer of the Buccal Cavity,
Dr. C. C. Simmons.
Cancer of the Uterus,
Dr. G. A. Leland, Jr.

Laboratory Work in Bio-Physics,
Dr. W. T. Bovie.

Radium in the Treatment of Leukaemia,
Dr. G. R. Minot.

Radium in the Treatment of Cancer of the Genito-Urinary Organs,
Dr. G. G. Smith.

The Treatment of Cancer of the Nose, Throat and Accessory Sinuses,
Dr. D. C. Greene.

THE BOSTON DISPENSARY.

Thursday, November 16, 1922.
11:00 A. M. to 1:00 P. M.

1. Medical Department: Dr. William E. Preble and Associates: Demonstration showing cases and illustrating methods of diagnosis, particularly cancer in the gastro-intestinal tract.

2. Dermatological Department: Dr. Henry J. Perry: Cancer of the Skin and Its Treatment by Radium.

3. Surgical Department: Dr. Hilbert F. Day.

4. Laboratory Department: Demonstration of Specimens and Slides: Dr. William A. Hinton.

The Dispensary will also offer a Free Clinic on Thursday, November 16th, on which day patients having or fearing they have cancer may come for examination without charge.

MASSACHUSETTS GENERAL HOSPITAL.

SURGICAL AMPHITHEATRE,

Friday, November 17, 1922,
10 A. M.

10:00—The Control of Cancer: Dr. R. B. Greenough.

10:15—Cancer of the Skin: Dr. C. J. White.

10:30—Cancer of the Lip and Mouth: Dr. C. C. Simmons.

10:45—Cancer of the Nose and Throat: Dr. D. C. Greene.

11:00—Cancer of the Stomach: Dr. C. L. Scudder.

11:15—Cancer of the Colon and Rectum: Dr. E. P. Richardson, Dr. L. S. McKittick.

11:30—Cancer of the Breast: Dr. R. B. Greenough.

11:45—Cancer of the Uterus: Dr. Lincoln Davis.

12:00—Cancer of the Genito-Urinary Organs: Dr. J. D. Barney.

12:15—The X-Ray Therapy of Cancer: Dr. G. W. Holmes.

BOSTON CITY HOSPITAL.

CHEEVER SURGICAL AMPHITHEATRE.

Saturday, November 18, 1922,
10:30 A. M. to 12 M.

In coöperation with the Cancer Week Campaign of the American Society for the Control of Cancer, the following symposium will be held in the Cheever Surgical Amphitheatre. Physicians, students and nurses are welcome.

The Pathologist's Conception of Cancer: Dr. F. B. Mallory.

Early Recognition of Uterine Cancer: Dr. R. M. Green.

Roentgen Differentiation of Gastric Malignancy and Chronic Ulcer: Dr. F. P. Butler.

Premalignant and Early Malignant Skin Lesions: Dr. T. W. Thorndike.

Symptoms Suggesting Concealed Malignancy: Dr. R. C. Larrabee.

Detection of Malignancy of the Genito-Urinary Tract: Dr. H. H. Howard.

Radium and X-Ray: Indication for Their Use: Dr. Herman Osgood.

Surgical Procedures for Removal of Malignant Growths: Dr. Halsey Loder.

Correspondence.

ERRATUM.

Oct. 23, 1922.

Mr. Editor:

My attention has been called to the fact that, through a misunderstanding, I have made an error in my article on "An Investigation of the Reliability of Laboratory Tests, Etc.," recently published in your Journal. In Part I, I stated in relation to Dr. L. S. Medalia's work: "On his request typewritten copies of the technique in use were submitted from the Boston Health Department Laboratory, the State Health Department Diagnostic Laboratory, the State Wassermann Laboratory and from the Board of Health Laboratories in Brookline, Cambridge, and Somerville." Instead, it should have been stated that he visited each of these laboratories and by questions and observations obtained information concerning the technique in use. This information he had typewritten and submitted to the various laboratories for approval; so that these data were gathered at considerable expenditure of time and effort on Dr. Medalia's part.

I will be grateful if you will publish this correction.

Very truly yours,

F. H. SLACK, M.D.

EASTERN HAMPTON MEDICAL ASSOCIATION.

The Eastern Hampton Medical Association will meet at the Hotel Bridgeway, Springfield, Thursday, Nov. 2, at 4.30 p.m. Theme: "Luerhemicosis." Speakers: Drs. H. B. Perry, S. D. Rumliff, F. H. Smith, C. J. Spauld, G. L. Woods. E. Y. Myers, M.D., Sec'y.

DR. W. W. KEEN'S ADDRESS ON THE OCCASION OF THE BESTOWAL OF THE BIGELOW MEDAL.

This valuable and interesting contribution to medical literature should be read by every physician and surgeon. A few copies are available and may be secured by applying to the BOSTON MEDICAL AND SURGICAL JOURNAL.

THE MASSACHUSETTS MEDICAL SOCIETY.

JOINT MEETING OF THE BARNSTABLE, BRISTOL NORTH, BRISTOL SOUTH, AND PLYMOUTH DISTRICT SOCIETIES.—The meeting will be held at the Lakeville State Sanatorium, Thursday, Nov. 9, 1922. Luncheon will be served at 1.00 p.m. Program at 2.30 p.m. Speakers: Dr. John W. Bartol, President of the Massachusetts Medical Society; George Chandler Whipple, S.B., Professor of Sanitary Engineering, Harvard University, "Mosquito Control in Massachusetts"; Dr. Eugene R. Kelley, Commissioner of Public Health, Commonwealth of Massachusetts; Benjamin White, Ph.D., Director, Division of Biological Laboratories, Massachusetts Department of Public Health, "The Schick Test" (A Schick demonstration will be given at the conclusion of the program.); Dr. Richard P. Strong, Professor of Tropical Medicine, Harvard Medical School, "The Gorgas Memorial Institute." All fellows of the combined district societies are cordially invited to be present at this meeting.

SUMNER COOLIDGE, M.D., *President*.

ARTHUR R. CRANDELL, M.D., *Secretary*.

DISEASES REPORTED TO MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH.

WEEK ENDING OCTOBER 21, 1922.

<i>Disease.</i>	<i>Cases.</i>	<i>Disease.</i>	<i>Cases.</i>
Anterior poliomyelitis	6	Ophthalmia neonatorum	12
Chicken-pox	60	Pellagra	1
Diphtheria	236	Pneumonia, lobar	49
Dog-bite requiring anti-rabic treatment	10	Scarlet fever	112
Encephalitis lethargica	2	Septic sore throat	2
Epidemic cerebrospinal meningitis	1	Syphilis	32
German measles	2	Suppurative conjunctivitis	6
Gonorrhea	133	Tetanus	3
Influenza	3	Tuberculosis, pulmonary	110
Mumps	39	Tuberculosis, other	14
Measles	139	Typhoid fever	12
		Whooping-cough	161

ERRATA.

In the article in this issue under the title "New England Hospital Association," on p. 637, under cross infection rate, the figures 63, for the year 1912, should be 62, and 17, for the year 1913, should be 17.

SOCIETY MEETINGS.

DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District:—Ipswich, November 3, 1922, February 2, 1923, (Annual Meeting).

Bristol South District:—Fall River, November 2, 1922, May 8, 1923.

Essex North District:—Haverhill, (Semi-Annual Meeting)—Jan. 8, 1923. Y. M. C. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Suffolk District:—Combined meeting of Boston Medical Library and Suffolk District, November 22, 1922; December 27, 1922; January 31, 1923; February 28, 1923; March 28, 1923; Annual Meeting, April 25, 1923.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Hist. The date for each speaker has not been assigned.

Middlesex North District:—Meetings; Wednesday, January 31, 1923.

Worcester District meetings in Worcester, Nov. 8, Dec. 13, 1922, Jan. 10, Feb. 14, March 14, April 11 and May 9, 1923, the last named date being the annual meeting.

A joint meeting of the Plymouth, Bristol North, Bristol South and Barnstable Districts will be held at Lakeville Sanatorium, Middleboro, on November 9, 1922.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

November, 1922. Massachusetts Society of Examining Physicians, (Date and place of meeting undecided), Hilbert F. Day, Secretary. National Cancer Week, November 12 to 15.

December, 1922. New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 2.30 p.m., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

January, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston, W. H. Allen, Mansfield, Mass., Secretary.

February, 1923. New England Dermatological Society Meeting, February 14, at 3.30 p.m., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

March, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary.

April, 1923. New England Dermatological Society Meeting, April 11, 1923, at 3.30 p.m., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston, W. H. Allen, Mansfield, Mass., Secretary.

May, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided). American Pediatric Society Meeting, May 31, June 1 and 2, 1922, at French Lick Springs Hotel, French Lick, Ind., H. C. Carpenter, Secretary.

June, 1923. American Medical Association, San Francisco, June 25-29, 1923, Alexander R. Craig,* Chicago, Ill., Secretary.

July, 1923. Massachusetts Association of Boards of Health, July 26, Nantasket, W. H. Allen, Mansfield, Mass., Secretary.

*Deceased Sept. 2, 1922.

The Massachusetts Medical Society

OFFICERS ELECTED BY THE COUNCIL JUNE 13, 1922

1922-1923

PRESIDENT

JOHN W. BARTOL, 3 Chestnut Street, Boston, 9.

VICE-PRESIDENT

CHARLES E. MORGAN, 24 Central St., Somerville

SECRETARY

WALTER L. BURRAGE,
42 Elmut Street, Jamaica Plain, 30

TREASURER

ARTHUR K. STONE,
Auburn Street, Framingham Center.

LIBRARIAN EMERITUS

EDWIN H. BRIGHAM,
Brookline; Office, 8 The Fenway, Boston, 17.

NOTICE TO THE FELLOWS OF THE MASSACHUSETTS MEDICAL SOCIETY.

CHANGES OF ADDRESS.

In view of the action of the Council, February 1, 1922, in advancing Librarian E. H. Brigham to the honorable position of Librarian Emeritus, after a continuous service of thirty-seven years, in future, all communications as to membership, especially changes of residence and address, should be sent to the Secretary of the Society, who keeps a constantly corrected official list of the Fellows and their addresses.

CONVALESCENCE: I. A CHRONOLOGICAL REVIEW, TO 1878.

BY JOHN BRYANT, M.D., BOSTON.

INTRODUCTION.

The general subject of Convalescence occupies a rather unique position. On the one hand, the early recognition of the importance of this transition stage between sickness and health is witnessed by the writings of Hippocrates and his successors; and appreciation of the necessity for giving organized consideration to the period of convalescence had already reached such a stage that in Paris both the Hotel Dieu and the Charité Hospital, in 1640 and 1650, made special provision for the care of convalescent patients. On the other hand, although there doubtless are in the literature numerous references to various aspects of convalescence under other titles, and although a French reference in 1877 by Brochin listed a bibliography of 136 titles, there were available previous to 1920 in both the Index Medicus and the Index of the Surgeon-General's Library, a total of only ninety-two articles listed under the general title of Convalescence.

This absence of any extensive literature seems accurately to mirror the chronic apathy of the medical profession with regard to serious interest in the subject of convalescence,—a lack of interest which is doubtless promoted by inade-

quate instruction in the subject at all medical schools. This lack of instruction is perhaps itself in part based upon the fact that the period of convalescence is not a subject well adapted to easy demonstration in the clinic or lecture room; obviously, where changes are demonstrable in weeks rather than in days or hours, there is nothing comparable for teaching purposes to the visibility of a broken leg, or the acoustic demonstration of the flatness of a lobar pneumonia as indicated by a slap on the back with the flat of a hand.

The total result of this lack of interest is that with the exception of a few shining examples such as the Burke Foundation, care of convalescent patients has for the most part been left to drift by itself without intensive medical supervision; in consequence, this is almost the only branch of medicine which has made minimal progress in the last fifty years or more.

It is now authoritatively stated that every city should provide beds for convalescent patients in the ratio of 1:10 acute hospital beds. All cities fall far below this estimate in their provision for convalescents, yet even such homes for this class as do exist are for the most part not used to capacity, and almost none are under the daily care of an interested and experienced physician. The result is that the funds of such institutions for convalescents as do exist are not used to best advantage; the patients either waste their own time or it is wasted for them and they are sent back to work in a condition of health

less good than they had a right to expect to find themselves in, at the conclusion of a definite period of care which should average about three weeks. Bridgman has proved that the average patient who has previously been sufficiently ill to require the average stay of 18-20 days in an acute hospital, has also been sufficiently ill to require an additional average period of three weeks of intelligent care during convalescence; not otherwise can this average patient be considered to have sufficiently recovered his health, to make it reasonably certain that he can successfully hold down a permanent job.

Not only is a lack of medical interest in convalescence noticeable in individual institutions, but such knowledge as has been accumulated is not passed on from generation to generation. Thus, although definite convalescent experience was acquired, for example, by England during the Crimean War, and by this country during the Civil War, practically all the nations engaged in the recent World War failed to profit by such previous experiences; this resulted in decreased efficiency of the war machines and necessarily increased wreckage of the individuals thus neglected. Running true to form, it appears that we are already in a fair way to forget what we have learned with regard to convalescence from our own most recent war experiences, before the next disaster arises.

One object of the present publication will have been accomplished in so far as it results in converting the prevailing attitude of passive neglect, into one of active, not to say, aggressive interest in the convalescent patient and chronic invalid. Such a change in the general viewpoint can be based only upon a widespread knowledge that more can be done than in the past has been done, upon how to do it, and upon the reasons why it should be done. That more can be done than has been done, will be shown hereafter; also, how it may be done, or at least some ways of doing it.

The reasons why it should be done, or the more obvious of them, will be clear to anyone who will consider the subject for even a moment. There are three points of view: that of the community, the hospital, and the individual patient.

To the community, the individual represents in varying degree and in accordance with his total value as a moral physical and economic efficiency unit, an asset, a cipher, or a potential or actual liability. Every working day lost interferes by just so much with the industrial efficiency of the community in which the sick man lives. The economic loss may be figured out at the end of a week or of a year, and should in some way be made good, either through previous earnings of the patient, or at the expense of some other person or organization.

The hospital point of view includes that of the social workers and the poor relief agencies. On the one hand, with every unnecessary day

passed in hospital there is a double financial loss: the institution itself is put to unnecessary expense which must eventually be made good through additional requests for financial support from its benefactors; and the patient is deprived of just one additional day's wages which he would have earned if physically able to be back on his job again. On the other hand, if the patient is discharged too early in recovery, he again becomes an object of obligatory interest to the social worker and the relief agency, by whom arrangements must be made for the financial support of perhaps not only the patient but his dependants until such time as full working power is re-established in the patient; here again, the financial loss is double, since to the outlay by the relief agency must be added the loss in wages of the worker.

The individual patient has a point of view in no wise different from that of the community or the hospital except that it is necessarily more personal, for in this case also the problem of convalescence may be reduced to the common denominator of costs. Even in the distant past, Plato knew that the poor man had no time to be sick, and a century ago Robertson wrote that "for the feeble and disabled of our manufacturing population, poverty renders lingering sickness in every instance a heavy and often an irretrievable calamity." But in the case of the individual, precisely because the point of view is more personal, there is proportionately more mental suffering which may easily in its turn become a very real factor in delaying still further the actual convalescence of the patient.

From every point of view, therefore, there is but one conclusion. Putting aside all sentimental, moral, ethical or other considerations, it can be demonstrated that the active and intelligent care of convalescence will pay utilitarian dividends; in a word, the community which invests money in improving the care provided for its workers during convalescence, will earn regular and continuous returns no less certainly than if the same amount of money had been invested in government bonds. With even greater certainty such a community will be storing up treasures of another kind for itself, of immediate and increasing value, in the shape of the multiplying health, happiness and prosperity of its individual workers.

To facilitate to the greatest possible extent the dissemination of interest in any subject, easily available knowledge is necessary.

Information upon the subject of convalescence is, however, not easily available. On the contrary, it is for the most part rather well buried in old or foreign literature, or in hospital reports not widely known.

With the above facts in mind, the following review of the literature is presented. It is to be the first of a series of papers upon various aspects of convalescent work. It is hoped that

these papers may to some extent supply the available information upon the existence of which must depend a rational and effective growth of interest in a vital phase of modern preventive medicine.

1732-1800.

The Surgeon-General's Index gives only seven titles under "Convalescence," previous to the year 1800. Of these only one, the earliest, was available at the Boston Medical Library. This was a graduation thesis by Heylerus, published in Leipzig in 1732 under the title "*De Statu Convalescentia.*"

Heylerus gave a general review of various types of disease, and presented a list of drugs and foods which might aid in convalescence; his thesis was, however, mostly given over to abstracting the opinions of earlier authorities. Thus, Celsus advised rest after meals. Hippocrates was quoted frequently; among other things he advised moderation in exercise. Sydenham referred to the importance of hygiene. Seneca insisted upon peace of mind. Galen advised riding and travelling. Hoffmannus referred to the necessity for tranquil sleep in promoting a return to health. In addition, Caledonius, Solon, Cato, Wedelius and various other early notables were quoted in what was essentially a summary of all knowledge which in the year 1732 might be brought to bear to improve the care of convalescence.

1800-1878.

The example set by Heylerus in writing a graduation thesis upon the subject of convalescence seems to have been followed extensively at the French Universities during the first half of the last century; at least, the majority of the titles in the Surgeon-General's Index under "Convalescence" dating from this period, are of this character. This seems to have been a symptom of the increasingly wide spread of interest in convalescence in these earlier years of the last century, for numerous articles upon the subject were written not only in France but in England and America. Two of the graduation theses will suffice to suggest the sympathetic attitude of the French toward the convalescent patient of the early nineteenth century.

Foureaud wrote in 1802, under the title "*Doit-on laisser les Convalescents avec les Malades?*" This is a question which is today no less fundamental although perhaps less obvious than at a time when the patients were more likely to die than live if they remained in hospital a single unnecessary day after the termination of the acute stage of disease. Foureaud appreciated the fact that "convalescents, who in their feebleness approach the condition of infants or the elderly, must have food appropriate for these persons." He also recognized that "food in its passage through the hospital halls acquires dis-

agreeable odors in spite of all precautions," and that "for this reason alone the convalescents should be separated from the sick." He emphasized the necessity for moral as well as physical care, and stressed the value of light and air as aids to returning health. The necessity for light, he placed also upon the special basis of avoidance of the fears which might be engendered by remaining in darkness or in a darkened room. Games and amusements were highly recommended as promoting "the tranquil spirit necessary for recovery," and Foureaud firmly believed that "all causes tending toward fear or depression must be avoided or excluded in order to promote a favorable psychic state." He, therefore, logically concluded that "for every conceivable reason, the convalescents should be separated from the sick."

A few years later, Maret in 1834 wrote upon "*Considerations Générales Sur La Convalescence.*" He, too, mentioned the "capriciousness" of the appetite of the convalescent. In addition, he referred to the characteristic increased nervous irritability, the poor circulation and the muscular exhaustion progressing at times to a point where the "least movement causes pain and fatigue." The poor memory of the convalescent and the failure of the imagination were noted, as also the fact that an attempt to walk might result in such trembling as to make it impossible for the weakened patient to sustain his own body weight. In the way of treatment, fresh air and sunshine were considered absolutely necessary, but it was appreciated that "cold is the enemy of the nerves"; consequently the use of woolen clothing was advised. Also, he approved the use of simple but good food, and controlled exercise for the improvement of the muscular system. Maret further realized that drugs were seldom needed, that occupation was desirable, and that depression must be avoided; concluding, he emphasized the fact that fundamentally recovery depends upon the "regaining of moral and intellectual control over the body."

The undesirability of promiscuous drugging was recognized by Cook, writing in this country in 1833. Cook also well understood the fact that many convalescent patients were brought almost to a point of death or at least to the point of retardation of expected progress by well-meaning but over-officious friends. Leaving the undesirable ministrations of friends out of consideration, however, he was confident that improper bowel action was the fundamental cause of delayed convalescence. He realized that moderation in diet was necessary; if there were no appetite, he believed that food should not be forced since it merely resulted in "a heavy stomach, wind, sour fluid, griping, and looseness." Exercise, he held to be important, but knew it to be equally important that the exercise should not cause the patient actually to overdo. He intended, therefore, to hold the patient back from

exercise rather than to force him beyond his strength, saying that where health prevailed ambition and desire would soon enough return. The following observation by Cook concerning the use of opiates in insomnia will bear repetition. "Insomnia is due to too much appetite and too little exercise. It is a small inconvenience, which may be lightened very much not by yielding to impatience about it, but by giving over one's mind to thinking upon those important subjects which every man of sense ought to be glad of an undisturbed opportunity of considering."

In England at this period, various writers were alive to the importance of the care of convalescence,—as witness an article by Robertson in 1837. Robertson contrasted the differences in the average duration of life between the English operatives at Manchester and the savage races. He indicated that although the total duration of life was greater in English operatives, chronic illness was enormously higher for the Manchester operatives than for the savage races, about three-fourths of the population of Manchester requiring medical assistance of some form each year. Robertson then discussed the impossibility of producing real improvement in an operative chronically ill, without getting this operative away from unfavorable home conditions. He pointed out the large numbers of retreats for convalescents available for the wealthy, concluding with the following sentence:

"If then the opulent have, long since, discovered that a convalescent's retreat is good for them, will any venture to say that it is not equally good, and infinitely more necessary, for the feeble and disabled of our manufacturing population?"

After outlining the character of the Homes for Convalescents which he recommended, indicating that individual homes should have about one hundred beds, Robertson said it should be understood that no persons laboring under active forms of illness should on any account find admission. He then added the following:

"It has been suggested to me that such a retreat ought to be within six or eight miles of the town to which it belongs, rather than farther off; but there are many reasons why it should not be within a short distance, and why it ought to be on the sea coast. In the first place, it would require (supposing the town to be inland, and this I am all along supposing), the expensive purchase of a large space of ground, in order to secure to the convalescents sufficient room for exercise; whereas on the sea coast there is

with the most perfect change of air, and what is of importance to people from inland parts, complete novelty of scene, unbounded range without risk of trespassing on private property. In the next place, it is essential, in such an institution, that it be quite removed from the intru-

sion and frequent visits of the relations and friends of the convalescents."

Robertson offered the following reference to early French care of convalescents:

"In Howard's account of his inspection of the Hotel Dieu at Lyons, in 1775, allusion is made to two large upper rooms, airy and pleasant, named 'Chambres de Convalescence.' To these they remove patients that are recovering, and those whom I saw there said they were very refreshing. They came down from them at meals to a refectory or hall. These rooms soon complete the patient's recovery."

A graduation thesis written in 1844 by Vidard-Dupin, "*Du Régime Alimentaire Dans La Convalescence*," shows the continuing French interest in the diet of the convalescent patient. This author stated most emphatically that "convalescence no less than disease belongs to the physician," especially with regard to the diet. The blood he recognized as the "moderator of the nervous system," and stated that the muscles "must be refreshed in order to cause a disappearance of the preponderance of the nervous system." He recognized that great care was necessary to avoid sudden death from too rapid eating after fasting. Vegetables he considered less efficient in appeasing the appetite than animal foods; he also believed they gave less strength. Among special dishes, he mentioned the use of gelatin, fresh butter, fresh cheeses and the starchy foods. Vidard-Dupin was aware of the undesirable effects of nervous anxiety and stated that it was the business of the physician (a) to produce in the patient a tranquil spirit, (b) to see that he avoided all excesses, and (c) to allow him whenever possible, any especially desired foods. As an appetizer he approved of taking a bath an hour before meals, following this with friction by dry flannel. In conclusion, the advice is given that in the treatment of the individual convalescent patient, age, sex, temperament, habits, climate, the seasons, and all other complications must be carefully considered.

The recognition of the existence of the problems of convalescents in the care of soldiers during wars is, doubtless, very ancient. MacLean, however, writing in 1867, leaves it a matter of record that active divisions of convalescents existed in the medical department of the British army during the Crimean War. Incidentally, it was MacLean who provided Da Costa with his nomenclature of "Irritable Heart." MacLean was the first to report the extensive occurrence of the "Irritable Heart" in soldiers. He stated that they were found "not only in the regular medical and surgical divisions, but also in the convalescents' divisions." His general observations upon the characteristics of these substandard soldiers are summarized in the following sentence: "the official nomenclature in use in the service has no heading under which to in-

clude what may be called the 'Irritable Heart'—that rapid tumultuous action so common among soldiers; and which, once established, is never got rid of so long as a man remains in the Army and wears the dress and accoutrements of the infantry soldier."

Da Costa, following MacLean's nomenclature, reported in 1872 upon his own Civil War cases of "Irritable Heart." He referred to his own use of classification for soldiers in groups according to various degrees of physical disability, and emphasized the necessity for giving more attention to the period of convalescence as a means of improving physical efficiency within the Army.

A few years later, Brochin (1877), again in France, reviewed the clinical and the historical aspects of convalescence interestingly and in detail in two long articles for the "*Dictionnaire Encyclopédique des Sciences Médicales*." These articles are so comprehensive and the other literature upon convalescence is so scanty, that it has seemed desirable to abstract from Brochin at length in order that his work may be more accessible to students of Convalescence than as originally published in an old French Encyclopedia of Medicine.

"*Convalescent Hospitals*.—There were in Paris, in the seventeenth century, two hospitals for convalescents: the division of the Hotel Dieu, and that of the Charité. The convalescents' section of the Hotel Dieu was founded about 1640, and that of the Charité in 1650. The cause of the disappearance of these sections lies less in the disorders which increasingly augmented the number of convalescents at the Hotel Dieu than in the necessity which existed at the commencement of this century, of providing shelter for all the acutely sick. There were then in hospital, according to the calculations of Tenon, two-thirds acutely sick and one-third convalescent. It was, however, recognized that wards for convalescents were indispensable. A royal ordinance under date of 1781, concerning the military hospitals, indicated the reasons which in the preceding century had determined the creation of special hospitals for convalescents. It was said in this ordinance that 'to obviate the prolongation of convalescence, occasioned by the bad quality of the air breathed in the acute hospitals, there should be established in connection with the principal military hospitals, and above all in connection with those situated in cities where the air is particularly damp, hospitals for convalescents, which should be located either in neighboring towns or in the country.'

"In the hospitals which, after the plan of Tenon, were to replace the Hotel Dieu in Paris, the convalescents were to be placed on the ground floor, convenient to dry walks, warmed in winter, etc.

"The committee of the Academy of Sciences, reporting upon the hospital situation, expressed

itself as follows: a hospital in which one proposes to cure people, should take care of its convalescent patients. The ground floor, sufficiently raised above the soil, should be especially reserved for convalescent patients,—an arrangement which will facilitate for them not only walking, but the exercise of their increasing strength in the open air, etc.

"Later, the general council occupied itself on several occasions, as in 1802, 1824, and 1838, with methods of protecting convalescent patients from the infected air in the regular wards; but for various reasons which would take too long to enumerate here, these projects never came to anything.

"In short, from the time of the closing of the convalescents' hospitals of the seventeenth century, the situation as it existed with regard to convalescents in the regular hospitals underwent not a single modification. The convalescents continued intermingled with the seriously ill patients,—a deplorable system of promiscuousness which had indeed claimed a sufficient number of victims, when in 1855 the Emperor Napoleon III, struck by these dangers, decreed the foundation of special hospitals for the care of convalescent patients of the working classes. The decree under date of March eighteenth which created or, rather, re-established, this mode of public assistance, stipulated among other things that these hospitals should be open to convalescents of the working class, especially to those who had been injured in the course of their daily work; also it stipulated that in the case of those qualified for admission to the hospitals, but yet desiring to remain at home, the right of admission could be converted into a monthly or annual grant.

"*Convalescent Hospital of Vincennes*.—The foundation stone of the Hospital of Vincennes was solemnly laid on the fourteenth of August, 1855, and on the thirty-first of August, 1857, two years later, the institution was opened.

"On the following twenty-eighth of October an imperial decree classified the hospital among the general charitable institutions, and placed it under the authority of the Minister of the Interior.

"The original plan provided for 460 convalescents, but the rapid development of the institution which, in 1861, had already received 7752 patients, produced a state of affairs which made necessary an increase in capacity. Additional wings were, therefore, constructed, which brought the total capacity of the institution to 522 beds for convalescents.

"The hospital, constructed opposite the Maison de Charenton, and located in the midst of about 40 acres of land set aside from the park of Vincennes, is composed of two long wings on either side of a central pavilion. Near the entrance, to right and left of the driveway, there are located in two lateral pavilions the quarters

of the personnel and administrative services. In the centre, along the axis of the main pavilion, are placed all the general services; the rooms and dormitories for convalescents occupy the ground floor and the two stories of the main wings and the pavilion.

"The hospital itself is surrounded by gardens, with pleasant views across an extensive and carefully planted park.

"The buildings themselves are laid out from east to west in such a way that the wings destined for living quarters are exposed to the sun at noon, with agreeable views across the gardens and the park.

"The individual rooms, arranged to contain three beds each, are located on the ground floor, above which are two stories reached by staircases situated at the ends of each wing. All the corridors for the rooms are on the north side and terminate in two wide staircases on either side of the central building. The living quarters are warmed by heaters which maintain an average temperature of from 60 to 65° F.; a ventilating system changes the air at will throughout the year in the bedrooms. The corridors are lighted with gas throughout the night, the rooms only until bed-time, at nine o'clock.

"The infirmary includes one 16-bed medical ward, two surgical wards of 16 beds each, and a ward for infectious diseases to care for five patients. Aside from this, there is on the ground floor a ward of eight beds for injured patients who cannot be otherwise cared for easily.

"The dining-rooms, high of ceiling, paved with asphalt, and lighted on both sides throughout their length with large windows, are furnished with fixed marble tables and carved oak chairs. The kitchen is placed between the two dining-rooms, with its supply rooms in a basement, the two connected by an inclined walk to facilitate the transit of supplies.

"The hospital is administered under the authority of the Minister of the Interior, by a responsible director assisted by a consulting commission of seven members, one or more of the members changing each year.

"The medical care is divided between two chiefs of service, each assisted by three interns. The interns live in the hospital.

"The infirmary is in charge of a Sister with three assistants. When necessary, a Sister is on duty at night.

"A bathroom, adequate for sixteen bathers, and a room for hydrotherapy are at the disposal of the medical service.

"A Sister is in charge of the drugs, under the supervision of the pharmacist of the Charcotton Hospital. Prescriptions are limited to simple remedies.

"Every morning, excepting Sundays and holidays, the physicians make a ward visit at the hospital, accompanied by the interns, who in-

form them of developments since the previous day. The Sister in charge of the pharmacy examines the orders of the day and assures their carrying out.

"The interns alternate on duty throughout the twenty-four hours. They care for the ordinary medical needs of the patients; should there arise more serious necessity, they immediately inform their chiefs of service.

"*Rules for Admission.*—The hospital admits for the treatment of convalescence the following:

- 1—Those suffering injury or sickness resulting from their being engaged in public works in progress in the Department of the Seine;
- 2—Those belonging to mutual aid societies paying yearly retainers to the hospital to secure care during convalescence for their members;
- 3—Those working in industrial establishments the owners of which have contributed to the support of the hospital;
- 4—Those patients convalescent from hospitals in the Department of the Seine, or sent by charitable organizations.

"The hospital receives also, but on a pay basis, all other convalescents who do not fall into one of the four above groups; members belonging to mutual aid societies approved by the Department of the Seine are also received in the hospital.

"The price per day for those coming from industrial establishments as above, is seventy-five centimes.

"Those who do not fall into any of the above categories may be admitted at one franc per day.

"(When necessary, patients may have their charges reduced or are admitted free.)

"*Arrival of the Convalescents at the Hospital.*—Special conveyances collect the convalescents in Paris for transportation to the hospital, and return them to Paris on the completion of their stay. On arrival at the hospital, the intern on duty receives and examines the new patients, classifies them according to their condition, prescribes a routine and dispenses any urgent medication, should there be need of such previous to the next visit of the chief of service. If the chief of service should conclude that the convalescent patient is not strong enough to undergo the regular routine, he orders him to the infirmary.

"*Duration of Stay of the Patients.*—The length of stay of convalescent patients at the hospital is very variable. The usual duration is fixed at two weeks. After this length of time if the condition of the convalescent patient requires it the director can upon advice of the physician authorize the patient to remain in the hospital for a second two weeks; but at the end of this period, the director can obtain even fur-

ther extension of time should the physician judge it to be necessary.

"The average duration of stay is 21 days. The departure of the patients about to leave is announced on the evening previous to the day on which departure is effective. Those leaving are taken back to Paris.

"*Routine.*—The hours for meals have been in so far as possible fixed according to the habits of the workers; at 7 in the morning—soup; at 10 o'clock—the noon meal; and at 6 o'clock—dinner.

"It is perhaps of interest to mention a few details concerning clothing, sleeping, occupations, and the daily routine. Each convalescent at the time of his arrival is provided with special clothing composed in winter of a blue overcoat, with hat of the same material, a blouse and straw hat for the warm season, and a pair of sandals. The patients sleep upon iron beds provided with hair mattresses. Each convalescent has, in addition, the comfort of an arm-chair, and a clothes closet.

"The convalescents enter freely, stimulated by small cash compensations, into maintenance work, such as the repairing of clothing and furniture. They are also occupied in special departments of the hospital, in farming, in work upon the outside grounds, and in various of the services, such as the pharmacy, the room for surgical dressings, the kitchen, dining-rooms, laundry, etc.

"Various entertainments are authorized, for recreational purposes, and to occupy the spare time of the convalescents, a special room being set aside for these activities; they have as additional resources, walks in the park, among the flower gardens, under the shade of the trees in the formal gardens, etc.

"The convalescent patients are required to carry out a schedule only with regard to the hours of rising, ward visits of the physicians, baths, dressings, hours for meals, and any special work upon which they are engaged.

"Three times weekly, Sunday, Monday and Thursday, from 12 to 4, is the visiting hour for family and friends.

"In addition, the institution possesses a library, rooms for singing and for music, a large meeting hall, and even a theater which is used occasionally,—that is to say, whenever there are among the convalescent patients a sufficient number of persons who can take the necessary parts.

"A general report follows, covering the convalescent patients admitted to the institution and to the infirmaries since 1858, the first year in which the institution was in full running order.

"The published official medical reports show that in the period between 1857 and 1866, approximately 57,844 convalescents entered the hospital, 37,824 of whom were suffering with medical and 20,024 with surgical complaints.

"The most frequent medical complaints were as follows: Affections of the lungs, affections of the digestive apparatus, rheumatism, typhoid fever, smallpox, erysipelas, and accidents due to the use of toxic substances.

"On the surgical services, the most numerous cases were fractures, phlegmons, white swellings, eye complaints, and amputations.

"In the same period, with a total population of 57,844, there were 249 deaths, accounted for as follows:

Diseases of the lungs.....	61
Fevers	58
Diseases of the nervous system.....	46
Diseases of the circulation.....	24
Cachexias	16
Diseases of the digestive organs.....	10
Diseases of the joints.....	4
Diseases of the mouth.....	4
Diseases of the genito-urinary organs.....	2
Contagious Diseases	1
Contusions and Burns	1
Diseases of the eyes	1
Dropsy	1
Diseases of the skin.....	1
Epidemic diseases	1
Other Diseases	18

"*Convalescent Hospital of Vesinet.*—The hospital of Vesinet was built in conformity with the decree of March 8, 1855, and of August 11, 1859, to receive temporarily women of the working classes during convalescence. This hospital, constructed according to the plan of M. Laval, completed in 1859, was opened on September 29 of the same year. Situated toward the southwest corner of the Forest of Vesinet, in the commune de Croissy, this establishment is set in a park of approximately 90 acres, enclosed by walls. It consists of a large central building connecting with lateral wings by means of covered galleries. The central building contains on the ground floor the dining-rooms, and

on the first floor above, two work rooms separated by a chapel which occupies the central pavilion. The wings on the right side of the Court of Honor are three stories high and are used for the offices and quarters of the administration. The left wings are given over to quarters for convalescents. The individual wards contain from two to eleven beds, divided between the ground floor and the two upper floors. The total number of beds is 350, with in addition 50 beds for infants.

"These wings are provided with sanitary arrangements and hot and cold water.

"All the wards are heated with hot-air heaters, combined with a propulsion ventilating system for all seasons of the year, aided by a small vaporizing machine from which the exhaust steam is also used for the infirmaries and the baths.

"A vegetable garden, irrigated throughout its entire extent, is placed in the southwest corner of the park; between it and the main buildings is the dairy.

"The Hospital of Vesinet is administered under the authority of the Minister of the Interior, by a responsible director, assisted by a consulting commission.

"The personnel is composed of a director, an auditor, a chaplain, a physician, three interns, 15 hospital sisters, servants, etc. Convalescent working women residing in the Department of the Seine who are not sent through usual sources, such as hospitals, charitable organizations, and mutual aid societies, may be admitted on payment of a small daily charge.

"From the 8th of December, 1859, the day of the opening of the hospital, to January 1, 1866, there were received 22,504 convalescent women and 2263 infants.

"The average duration of stay at the hospital is 23 days. The admissions are highest during the months of August, September and October, and decrease markedly during the winter. Extensions of stay can be obtained by authorization of the Minister of the Interior, for convalescent women whose recovery is not completed. From 1859 to 1866 there were granted 1109 extensions of stay.

"The classes from which come the largest number of convalescents are: Domestics, dress-makers, washwomen, seamstresses, lady's shoe-makers, and florists.

"The physician makes a daily visit at 8 o'clock. The medical reports show that the most frequent diseases causing admission are typhoid fever, phthisis, bronchitis, pneumonia, and rheumatism. Next in frequency come chlorosis and chloro-anemia.

"One of the most numerous classes of patients is that of women following child-birth. They are sent in general from hospital services where they were delivered, about seven or eight days after delivery. A considerable number of these women come with their infants

whom they nurse. If an absence of breast milk occurs, or if the mother is sick, or if for any other reason the infant cannot take the breast, there is available a nursery located near where the mothers sleep.

"All infants arriving at the hospital with their mothers are without exception vaccinated if this has not been previously done.

"The infirmary contains 20 beds, intended to care for: Mothers arriving at the hospital so early in convalescence as to require special care, so that for this reason they cannot carry out the regular routine; convalescents with surgical complaints necessitating particularly careful dressings; convalescents made worse during their stay at the hospital, either by intercurrent disease, or by a relapse, or by accidents not sufficiently dangerous to require return to the hospital from which they came in the city of Paris. These three classes of patients fall under the same régime and receive the same care as those in city hospital wards.

"Admissions to the infirmary between 1859 and 1866 were 11,096 out of a total of 22,504 convalescents. The average duration of stay at the hospital was 25 days. From the time of the opening of the hospital there have been 76 deaths out of a total of 22,504 convalescents, including those in the open wards and in the infirmary, due to the following causes:

Contagious diseases	18
Diseases of the lungs	15
Fevers	15
Cachexias	12
Diseases of the circulation	8
Diseases of the genito-urinary organs.....	2
Diseases of the digestion	1
Diseases of the nervous system	1
Other diseases	4

"Deaths among the infants accompanying their mothers to the hospital are very numerous. In 1861, of 296 infants, 54 died; in 1862, 26 of 267; in 1863, 33 of 332. Beginning with the year 1864 the number of deaths decreased; in this year there were only 18 out of 456 infants, and in 1865 there were only 30 out of 688.

"*Private Convalescent Hospitals.*—Private charities also maintain convalescent hospitals for the poor. There exists in Paris a society for the care of convalescent children, which is carried on by the Sisters of St. Vincent de Paul, where are received in the convalescent home (located in Sèvres) poor children recovering from disease; there are received here also convalescent adults."

At the conclusion of his historical review of the subject of convalescence, Brochin summarized the other efforts in France then being directed toward care of convalescents. Thus, there were in Paris five private homes for convalescents, aside from the homes designed to care for women immediately after child-birth; also, there were accessible to the city two homes for

the children of Paris, one for boys and one for girls.

At Lyon, there was in operation a public convalescents' hospital for men, called the Hospital of Sainte Eugénie. This establishment, founded through the initiative and munificence of the Empress Eugénie, who gave the sum of 200,000 francs for the purchase of the Chateau of Longehene, was opened in 1867. It was situated six kilometers from Lyon. On recommendation of the physicians, poor convalescent patients leaving the Hotel Dieu and the Red Cross hospital could be taken there, when they so desired, in order to complete their recovery. The hospital itself contained 100 beds. The patients here had not only the pleasure of walking through the extensive and beautiful grounds, but were allowed to engage, according to the limits of their strength, in farming and other outdoor work. Medical care was provided by one physician, assisted by two interns.

The women of Lyon, convalescent from serious illness, were less fortunate than the men, since at this time there was no similar institution available for them. Consequently such care during convalescence as they received had to be provided entirely by private charity.

Note.—Since the preparation of the above article for publication, the writer had the opportunity in early September of visiting both Vincennes and Vesinet, the two great institutions for convalescents for the men and women of the city of Paris, to which Brochin refers above. Surprising as it may seem, it was impossible from the literature to verify even the continued existence of these hospitals. They were unknown outside of Paris, yet they had been in continuous and successful operation throughout the 56 years since their opening, until the onset of the War in 1914. Then, as had happened to convalescents' hospitals in previous centuries in Paris, their 1000 beds were converted to military purposes for the care of the acutely sick.

Since the war, funds have not been adequate to maintain both institutions. Inevitably, the men suffer. Vincennes is still closed, although its early reopening is eagerly anticipated by physicians of the hospitals of Paris, who had been accustomed to depend upon it for the better care of their poor patients during convalescence. But the women's hospital at Vesinet has for over two years been functioning again as a civil hospital for convalescents.

On the day of my visit to Vesinet, 250 of its 350 beds had been made available in the gradual process of renovation necessitated by military occupation. All the beds available were filled. In addition, about 50 mothers with infants were being cared for in the nursery wing, sent there direct from city maternity hospitals.

The system of after-care does not stop here, and the French do not consider their responsibility ended on discharge of a patient from

Vesinet, for at a city branch of this institution, otherwise homeless girls are received and cared for free for ten days, or until they are actually again placed at a new job. Here is in operation an example of intelligent municipal medical follow-up work which other cities less well provided for may well study with care.

The sensations experienced by the explorer who comes suddenly upon a lost city in the jungle can hardly exceed those experienced by the writer when coming suddenly upon the magnificent grounds and buildings provided with such admirable foresight by the French for their convalescent men and women at Vincennes and Vesinet, a complete equipment which for practical purposes has been lost to the world outside of Paris for more than a generation.

It seems almost incredible that Vincennes and Vesinet should so long have remained "lost." It is, however, a fact, and it demonstrates better than many words the present apathy of the world at large toward the subject of "Convalescence."

New England Hospital Association.

ANNUAL MEETING MAY 17 AND 18, 1922,
AT BOSTON MEDICAL LIBRARY.

(Continued from page 637)

Thursday, May 18, 1922.

Meeting called to order at 10:25, by Dr. Howland.

DR. HOWLAND: I think it would be well if we could have the proceedings of these meetings published. It is not always possible for superintendents and others interested to attend and hear the papers. I think the papers have been exceptionally good so far, and I feel that it would be worth while to publish them, in an inexpensive way, if we are in a financial condition to do so.

On motion made and seconded, it was voted to publish the proceedings of the meetings.

DR. HOWLAND: I think this is a wise decision, because we probably will go on, and it seems a good thing to have a complete transcript of the business of the Association, and not wake up half a dozen years hence and regret that we have not a complete record. I think we can do it, in an inexpensive way, for distribution to all the members.

Dr. Washburn, the Chairman of the Legislative Committee, was called away. He had made an appointment with the Pennsylvania Hospital Association, which is being organized, to read a paper, not realizing that it came on the day of our convention. Dr. Sexton of the Hartford Hospital, Connecticut, will report for the Legislative Committee.

DR. SEXTON: I have to report that there has been no meeting of the committee. The Association was organized after all the legislatures of the different states had closed for the year. We have a session in Connecticut every other year, and have had no session since our organization. For that reason, there has not been a meeting of the Legislative Committee.

The Chairman then called for the report of the Membership Committee, Dr. Bresnahan, Chairman.

No report.

No report from the Committee on Constitution and Rules, Dr. Dowling, Chairman.

DR. HOWLAND: The next item is the reading of a paper on "The Hospital Laundry," by Dr. Harold W. Hersey, of the New Haven Hospital.

THE HOSPITAL LAUNDRY.

BY HAROLD W. HERSEY, M.D., SUPERINTENDENT OF THE NEW HAVEN HOSPITAL.

IN no department of the hospital is adequate equipment, efficient organization and standardized routine more essential than in the hospital laundry. The various wards must be supplied at regular intervals with clean, soft fabrics, free from pathogenic bacteria and disagreeable odors. To insure the delivery of this supply, the laundry must run with clock-like precision.

This result is only possible with an efficient manager, competent employees, cooperation among the employees, definitely assigned duties, adequate wage, modern machinery, and a well-organized and standardized routine for putting through the day's work.

With the equipment now furnished by the various companies manufacturing laundry machinery, it is possible for even the smaller hospitals to conduct a laundry on an economical basis, and as some hospitals are able to install new equipment or to plan for new laundries, we will start our discussion at that point.

In planning the laundry it is desirable to construct a building detached from the main hospital. Frequently, however, the hospital plot is too small or the plans for future development are such that this type of structure is impossible.

It should be borne in mind that laundry employees work in a super-heated atmosphere, permeated with steam and the odors of various chemicals, and that every effort should be made to overcome these conditions by providing for the circulation of pure air, and the removal of the foul air.

The building should be of fireproof construction with concrete, water-proofed floors, and so placed as to allow the maximum of sunlight at all hours of the day. For this purpose the factory type of construction with abundant windows is excellent. The rooms should be high studded, at least 15 feet in height, and if possi-

ble should be provided with a monitor type of roof or skylights.

The general arrangement of the laundry should be such that the work proceeds systematically, step by step, from one point to another, care being taken that at no point do these steps cross.

There should be an ample receiving and sorting room so arranged that if goods are brought in from an infectious or contagious patient they may be given a sterilizing wash before entering the laundry proper. The average sterilizing washer is so constructed that goods may be put in at one side, and when sterilization is completed at a pressure of 15 pounds for 30 minutes, removed at the other side or the receiving room proper.

It is well to have all goods checked on entering the laundry at this point, the results compared with the accompanying laundry slip and any discrepancies noted and reported.

The goods should, after being classified, proceed through the various steps with which you are all familiar, the washers, extractors, driers and tumblers, mangles, and so on.

In the receiving room the incoming goods should be examined and properly marked. It is well on issuing new linens to have the date of issuance marked on the fabric, as it is frequently desirable to ascertain the length of wear of such material.

In arranging the laundry it must be remembered that many cumbersome laundry trucks must pass and repass each other and ample floor space must be allowed for the workers and the necessary trucks and hampers. No plant can be efficient if crowded.

There are several very excellent washers on the market and the various manufacturers of laundry equipment maintain consulting engineers who will gladly advise upon the size and number of machines required for the present needs and future development of the hospital.

Over each machine and over each area from which heat or steam arises, a hood should be placed connected with an exhaust fan. The more modern equipment is operated by individual motors, thus effecting an economy when the machines are idle and eliminating the annoyance of belt-driven machines.

The William Wirt Winchester Hospital at West Haven, now leased by the Public Health Service and known as the U. S. Veterans Hospital, No. 41, is an example of the more recently constructed hospital laundry. This laundry is approximately 60 feet square and contains:

- 2 Cascade Washers
- 2 Extractors
- 1 Tumbler
- 1 Venturi Tumbler
- 1 Hurricane Dryroom
- 1 Flat Work Ironer (4 roll Hagen type)
- 1 Bosom Press
- 2 Cuff Presses

- 2 Garment Presses
- 1 Yoke Press
- 1 Collar Ironer
- 1 Neck Band Machine
- 1 Rotary Edger
- 1 Seam Dampener
- 1 Spray Dampener
- 1 Combination Table
- 1 Starch Cooker
- 1 Shaper (hot tube)
- 1 Collar Shaper

The power-driven machines are propelled by industrial motors.

Between 450 and 500 patients are cared for besides the necessary hospital personnel. 101,919 pieces of laundry were handled last month and the laundry payroll contains 18 names.

The washing machines should not empty directly into the sewers but into suitable concrete drains in the floors. This allows the wash-man to see the color of the water as it is drawn from the machine and prevents an occasional piece of goods from being washed into the sewer. The floor drain should be provided with a suitable screen.

The washing of goods depends upon the rapid agitation in warm water and suds, in a revolving cylinder, so arranged that the goods are carried through the soapy water, permeated by this solution, lifted to the top of the cylinder and dropped forcibly into the water below. The machine then reverses its action and revolves an equal number of times in the opposite direction. It is claimed that the reversal of the cylinder helps the penetration of the washing fluids and keeps the goods from becoming badly tangled.

It is interesting to note that at several of the recent conferences of State Laundry Associations, the advantages of washing the goods in nets and so adjusting the machines that the reversing action is omitted, have been discussed. The claims made for this method are that it requires less time to complete the wash; that the nets prevent the clothes from becoming entangled, and that less power is required to carry the load in one direction than to stop and start in the opposite direction.

Many laundries are replacing the liquid soap formerly considered essential, by powdered soap, and if it is carefully measured and scattered over the cylinder with the proper proportion of soda, I believe it to be efficient. The advantages are the saving of steps, a more accurate knowledge of the amount of soap used, the elimination of one cause of a slippery floor with its dangers, and a small saving in steam.

In buying clipped soap these soaps in which the fatty acids are largely from tallow are the best for laundry use. Not more than 12 per cent. of moisture should be present. It is poor economy to buy water at the price of soap. The Laundry Owners National Association recommend the following procedure to obtain

a rough estimate of the moisture content of soap:

"Weigh out on scales about five to ten pounds of soap from the center of a freshly opened barrel, and place the soap, spread out on a tray, in the dry room, and leave for several hours. Then let the soap cool to room temperature and at once weigh again. The first weight minus the last weight, divided by the first weight and multiplied by 100, is the percentage of moisture. Example: Weigh out 10 pounds of clipped soap. After drying it is found to weigh 8 pounds and 8 ounces, or $8\frac{1}{2}$ pounds. Then: $10 - 8\frac{1}{2} : 10 \times 100 = 15.0$ per cent."

We all know that in the washing process we are aided by the action of alkali and a soap, but do we know why we use alkali in this process?

An alkali when dissolved in water gives a solution with the following properties:

1. A brackish taste.
2. A soapy feel.
3. It turns red litmus blue.
4. It neutralizes an acid.

Soap is a product formed by the reaction of any base such as sodium, potassium or ammonium, with a fat. The three alkalies mentioned are soluble in water and are therefore of interest in the laundry industry.

Experimentally it has been found that solutions of soda ash, borax and other common alkalies will not wash lamp black, rouge and similar substances through a filter paper.

Soap solutions will wash these substances through the filter paper. Any of the alkalies will increase the amount of lamp black washed through the paper, and from the above it is seen that alkalies, while not detergent, greatly increase the detergent powers of soap solutions.

The reasons for using an alkali in washing clothes are, therefore:

- (1) to increase the detergent power of the soap.
- (2) to neutralize the acid substances found in some dirt on soiled linen.
- (3) to convert the greases present in soiled fabrics into soap and aid the detergent process.
- (4) to prevent the formation of a certain per cent. of lime soap in hard water, which causes the goods to feel gritty and frequently covers them with a sticky substance, imparting a grayish cast to the fabric.

The most suitable alkali for all around purposes is sodium carbonate, Na_2CO_3 , called soda ash.

An article by Dr. A. F. Shupp, Director of Chemical Engineering of the Laundry Owners National Association, appearing in the Laundry Journal of February, 1922, gives an interesting discussion of the action of soap and alkalies.

In washing it is customary to give a five minute breakdown in cold or lukewarm water

and soda to remove albuminous deposits, such as blood and perspiration and loose dirt. These albuminous deposits would be set by hot water. Tri-sodium phosphate is of value in removing blood stains.

In the different laundries different routine for washing may be found, dependent upon the type of goods to be washed and the amount they are soiled. Usually the cold rinse is followed by a hot suds bath for fifteen minutes in three inches of water, a hot water rinse in six inches of water, for fifteen minutes; a second bath in hot water, followed by a rinse, and in many cases bleach is used at this point when necessary, followed by the sour and sufficient rinsing. Neither too much water nor too much soap should be used. The clothes are more thoroughly cleansed in a shorter period in three inches of water than in six inches. In a 36"x64" washer, for example, thirty-three more gallons of water would be required when washing with eight inches of water than in washing with three inches of water, and three pounds more soap would be used.

From experiments carried on by the government, it appears that it is seldom necessary to employ a temperature higher than 140° F., maintained for ten to fifteen minutes to destroy pathogenic non-spore bearing bacteria. For example, the thermal death point of streptococcus was found to be 131° F., maintained for 10 minutes; micrococcus was found to be 140° F., maintained for 10 minutes; bacterium diphtheriae was found to be 140° F., maintained for 10 minutes; bacterium influenzae was found to be 140° F., maintained for 15 minutes. It was found that the effect of a temperature of 158° F., maintained for 5 minutes was the equivalent of 140° F., maintained for 30 minutes. Spore-bearing bacteria require boiling temperature for varying periods. It would seem, therefore, that as far as destroying the bacteria commonly encountered it is unnecessary to exceed a temperature of 180° F., which temperature will not injure fabrics.

To ensure the best results and allow standardization of work, each washing machine should be provided with an accurate thermometer, proper valves, and there should be a clock in a conspicuous place on the wall.

Many goods coming to the laundry are badly stained and require a bleach, and while it is not necessary to use a bleach as a routine, it should be used when necessary, and does little harm if used with consideration. The most common bleach is sodium hypochlorite or Javelle water.

After a thorough rinse a sour must be used to neutralize the alkali. Acetic acid is one of the best and the least harmful.

Time does not permit a further discussion of laundry procedure. It may be of interest to state that many of the tumblers are now provided with fresh air intakes, which impart a certain amount of freshness to the dried goods.

The belt ironers are being replaced to a large

extent by presses. For economical work these should be arranged tandem. A recent device now in use at the laundry of the Pennsylvania Hotel in New York, one of the largest hotel laundries in the country, and equipped to handle 20 tons of linen daily, is the Universal flat work folder, which may be attached to the regular roller ironer and used for folding flat work. The turbine-driven extractor is also of interest.

Accurate records of laundry output should be kept not only the daily and weekly results noted, but the supplies consumed and the weekly expense should be analyzed. Some hospitals compute the earnings of the laundry in terms of the charges made by the commercial laundry, but this does not appear to be entirely satisfactory.

A careful laundry manager will find many ways in which economies may be effected. Goods should never be thrown on the floor as the fibers are easily injured by the wheels of laundry baskets passing over them, or by the heels of the employees. Leaks from water and steam pipes should be controlled. Sharp corners on baskets, broken hinges on washers and tumblers, and loose covers on the cylinders of the washers may subject the linens to damage of tearing, and should be speedily repaired. The strong arm washer should not be countenanced.

It is well to observe frequently the activities in parallel lines of work, as for example the activities of the men interested in the commercial laundries. These men are a keen and progressive group of business men, and are raising the laundry industry to a high standard of efficiency.

The following illustrations are given. In the majority of the states the laundry owners have formed the State Laundry Associations, which hold enthusiastic conventions. Anyone interested in the laundry industry is welcomed at these meetings.

There is also a Laundry Owners National Association with associate membership open to hospital representatives. This Association maintains an industrial fellowship at the Mellon Institute of Industrial Research, of the University of Pittsburgh, in order to promote investigation of laundry problems. The Association now proposes the formation of an American Institute of Laundry Industry to provide a training for laundry managers, and to promote research in laundry problems.

There are several excellent publications dealing with the laundry, and these should be available to those in charge of hospital laundries.

In Massachusetts the laundry owners have interested the manufacturers of textiles in a co-operative movement to standardize fabrics and their manufacture. This movement is of interest to us for, should it accomplish its purpose, it will guarantee to a purchaser textiles of a standard quality, thus insuring a longer life for fabrics passing through the laundry.

I wish to acknowledge the assistance of the Hospital Library and Service Bureau of Chicago in the preparation of this paper. An extensive bibliography was furnished me by the secretary, and numerous articles on hospital laundries. I especially mention articles by Walter Trimble of Chicago. I would recommend to you for careful study a pamphlet published by the Laundry Owners National Association, called "A Manual of Standard Practice for the Power Laundry Washroom."

To summarize, it may be stated that the hospital laundry presents a problem whose satisfactory solution calls for efficient organization of the laundry personnel, standardization of labor, a definite schedule, accurate records, and efficient management, thus developing maximum results and minimum expenditure.

DR. HOWLAND: Dr. Hersey's most interesting and helpful paper is open for discussion. I am sure that no more practical paper could be presented than this on the subject of the Laundry.

Question: How do you handle the clothing of patients with contagious diseases?

DR. RICHARDSON: At the Providence Hospital we have never used a sterilizing washer, and I might say that, so far as we are able to ascertain, —and we have investigated a little,—no child has ever got a contagious disease from laundry sent back. Of course, if washing is done, as it is usually done in a commercial laundry, at a low temperature, say 40° or 50°, the chance of killing organisms is not great. While they might be got rid of mechanically, they will not be killed at that temperature. But as done in most hospital laundries, I think ordinary washing is sufficient. We experimented, putting clothes in a perforated receptacle in the centre of the laundry, and we found that those organisms, streptococcus, typhoid, and staphylococcus were practically all killed. We used from 30 to 60 minutes in washing, and most of the time the water was at a pretty high temperature. I also checked up the temperature of the water, and found that it averaged from 90° to 95°. I don't think it is necessary for any hospital to have a sterilizing machine. The objections are that they are more expensive; it is more work to do the washing in this manner, and the hot sterilizing water sets the stains in the clothes. I visited a good many hospital laundries, some of them contagious hospitals, and the linen was pretty black. It can't be avoided, if such high temperatures are maintained. Our linen is white, and compares favorably with any general hospital, because we do not use a sterilizing washer. This is of particular interest to small hospitals that can ill afford expensive sterilizing washing. From our own experience, I can confidently say that if the temperature of the water

during the washing process is 90° or 95°, that for practical purposes is sufficient. The only danger is in handling the laundry from the time it leaves the ward until it is actually deposited in the wash. We have clothes chutes. There is a door in the wall in the middle of the ward, with a little contrivance with spring hinges, so that the door can be opened with the forearm; the hands don't have to touch it. The linen from the beds, or towels, or other articles, are thrown into this chute, and fall into a canvas bag at the bottom of the chute. The chute is lined with galvanized iron, which has been painted. A great many hospitals have spent a lot of money on very elaborate clothes chutes. I saw one in Chicago that cost as much as a small hospital, which I don't think is at all necessary. We have washed these clothes chutes for a certain distance,—what can be done from the door, and they are not foul. Very soiled pieces are washed before they are thrown into the chute. The laundryman collects these bags on an ordinary barrel truck. He wears a gown and a pair of washable gloves, and whenever he wants to open a door or pull the elevator rope, he slips off one of the gloves. The laundry is put in front of the washer. He takes it out of the bag and puts it into the wash box. Such pieces as colored pieces and blankets we throw into barrels. He then throws his gown and his gloves right into the washer and proceeds to wash in the usual manner. It isn't difficult to get any intelligent fellow to do it, and to do it carefully. The danger from laundry has been exaggerated, anyway. Of course, it is theoretically possible to spread disease in that way. In twelve years I think we have had one laundry-maid get scarlet fever; I think that is all we ever had.

DR. SEXTON: We have had a good deal of trouble in ventilating our laundry. When I first went there, we put in patent ventilators. Up to that time, they had depended on windows for ventilation. We put in a patent ventilator to every 500 feet of floor space, and tried it for a couple of years; but notwithstanding their guaranty that condensation would not form and fall back on the floor, it occurred with every one of those ventilators. Then we took those all out, and put in a central ventilator shaft in our wash-room and ironing-room, 10 feet square, going up through. In the wash-room we converted it into a skylight, which gave us additional light, and at the same time all the ventilation area that was necessary. In the ironing-room we had to go up through two additional floors, so that rendered the making of that particular ventilating shaft into a skylight impracticable. We find these shafts have solved our problem of ventilation. Our laundry employees suffered intensely prior to the installation of these shafts, but now they are very comfortable on the hottest days we have. An advantage of

this method over patent ventilation is that it can be built by any ordinary hospital.

MISS COLEMAN, Good Samaritan Hospital: We wash the household linen and other linen at different times. We use the same wash-room; but they are not put in together.

DR. BAKER: I suppose we are all interested in the expense of maintaining a hospital, and in keeping the running expenses down. One way is to avoid waste and to avoid destruction. Starting with the laundry, I suppose certain destruction is due to our buying poor material, poor linen. We are not careful enough in selecting linen that will stand the wear and tear. Sometimes I think we buy too good linen. For illustration, take the heavy cotton huckaback towel; the average nurse is certainly wasteful; the huckaback towel is unwieldy to handle, and she starts to use it, casts it aside and takes a lighter one; it is easier to wipe dry with a light, pliable towel than with a heavy one. That means more labor and expense. Another thing I have found that costs some money is in bleaching. If particles of free chlorine get on the clothes directly, it leaves holes. That means destruction of your fabric. This comes from not carefully stirring it up or dissolving it. Another very common way of destruction is by the strong arm, the man hauling clothes out of the washer. We ought to be careful, also, about the padding on the mangle. Sometimes the padding is put there, and not changed, and gets worn, and that often means tearing of the fabrics. Another saving that I have found is in the sewing machine. Many of us maintain just an ordinary Singer machine, run possibly by a motor, for repairing the clothing from the laundry. The Singer people put out a heavier machine, which is much faster, and has a darning attachment which is very rapid, and will darn holes of from three to five inches in less time than one can patch them. In this matter of saving, I should like to have more small points brought out.

DR. HERSEY: Part of the cause of holes in linen which are found at different times, has been discovered to be due to the medicine glasses and solution glasses, sometimes put on tables by the bedside. Sometimes antiseptic solutions and sterilizing solutions are used, and some of the acids in those solutions frequently get on to the bed, which makes a hole. Then the clothing goes to the laundry and gives way, and some of the damage done in the wards is credited to the laundry. Along the same line, it has been found that if the hinges of covers on washing machines are not kept tight, some of the clothes get through the opening in the covers, and are pulled as the laundry revolves around, and some holes are due to that cause.

MR. SEAVINS: I should like to ask Dr. Hersey whether, in his opinion, the linen supply room

and the clean linen room, where the linen is brought from the laundry, should work together, or whether that room might be one room, from which all linen should be issued—whether it should be direct from the laundry, or direct from the supply room?

DR. HERSEY: For the distribution of the laundry, it would seem to be better to have a separate room. In one hospital I know the linen is all marked by the number of the ward. The routine in that hospital is to send down the linen to be sorted, and then the same amount of linen as comes down from the ward is returned to the ward, and the ward itself checks out the linen. In many hospitals, another method of distribution is used. The linen comes from the ward without any special mark; this is checked up and upon receiving the checked laundry list the person who brought the linen down goes to the linen room, and is reimbursed with new linen, issued from the central supply room. This is more satisfactory; it insures quicker delivery and prevents the head nurse from borrowing from different wards linen to make up accounts.

DR. PORTER: Does Dr. Richardson find it necessary to have a metal body washer? or is a wooden body suitable?

DR. RICHARDSON: We had wood in the beginning, and changed more as a matter of economy. The cylinder is brass, which lasts almost indefinitely.

DR. PORTER: Where you have metal inside the body, is it entirely satisfactory to have the outside wood?

DR. RICHARDSON: We had a wooden washer put in in the beginning, but the wooden cylinders gave out frequently; so as a matter of economy, we put in brass cylinders.

DR. HOWLAND: We might well take a lesson from this paper on Laundries to see whether laundries are properly lighted. Mr. Hixon made it clear that we can't have good work unless workers can see what they are doing. There is a type of reflector painted white inside that you can put inside of a high-power nitrogen lamp, which can be concealed by a little reflector that clamps on to the under side of the lamp, and gives a perfectly surprising distribution of intense light. It costs a few dollars only.

One great source of loss is not the strong arm only in washing, but in packing the extractor. The man throws in the clothes haphazardly across the extractor, and then more on top, criss-cross. Articles should be rolled up into a small mass and packed in around the edges and toward the center, so that when they are taken out they are not in a snarl. At the Brigham Hospital, when a new man is put on to the extractors, he

is given instruction by the engineer. We don't always escape torn linen, however.

DR. RICHARDSON: We have had cones put inside the extractors so that the lines won't stretch across the side. I don't know whether it has done any good or not.

DR. HOWLAND: I should like to ask if anyone has found a marking ink that can be used to mark linen—by which I mean flax, not cotton—and will be permanent. We have a National Marking Machine, and we have used all the various inks, but we can't find anything that will stay in linen. We have to use silver ink and mark by hand. The ink stays black for a long time in cottons.

No reply.

DR. FAXON: I should like to ask what results are obtained by those who use soap and water alone, and those who use soap and water and bleaches and the like. We have been trying for the last year, at the Massachusetts General, using nothing but soap and water on our clothes. Although I can't say that they are absolutely perfect, I think we get a reasonably good color, and certainly we don't incur the danger that comes with bleaches. Neither do we use any addition of soda.

DR. BAKER: Does Dr. Faxon mean soft soap?

DR. FAXON: We make our own soft soap, using grease from the kitchen, and cooking it in the usual manner. We have the chemist test it occasionally, to see that the man who is doing it is not getting careless, and is following the formula.

DR. BAKER: Will soap take out blood? Isn't it almost necessary to use a soda wash in order to get results?

DR. FAXON: After reading laundry pamphlets and talking with people, it seems as if we were doing something nobody else was doing; yet we seem to get satisfactory results. I think our linen is as good as could be expected. Of course, some clothes are stained.

DR. BAKER: Isn't that due to the fact that you add an excess of caustic in the soap solution?

DR. FAXON: No; the soap tests out what would be called neutral soap.

DR. BAKER: It is contrary to all blood chemistry.

DR. FAXON: I can't find anyone who thinks that it can be done. But the chemist makes an examination of the soap and reports a neutral soap, with no excess of alkali. The person in charge of the laundry has no soda, so that I

know no soda is used, and there is no Javelle water in the laundry. Yet we have linen that we don't get complaints about. We use quite a number of rinses, but I think no more than the ordinary laundry is using.

DR. HOWLAND: At the Brigham Hospital, we have a similar practice, but I think our soft soap has a considerable amount of alkali in it. It seems to us that our linen wears very well. I saw recently some pillow-cases stamped 1916, though I see plenty of things with a more recent date. We don't think that a soft soap, made from laundry grease and sodium hydrate, with a considerable amount of alkali, is bad. It is economy to use your kitchen greases and to make your own soap. In many hospitals it can be arranged to have the soap tank connected by an ordinary pump which will deliver close to the tubs. It is no work to step to the pump close to the tub and pump out soap. I should say that our soft soap had something like 8 per cent. free alkali. The linen certainly is white. No bleaches are used.

DR. FAXON: I believe a neutral soap is defined as containing a small amount of alkali, so that when you say "neutral soap," you have a leeway of several points.

DR. HOWLAND: Recently we have tested some hard soap for toilet purposes, and it showed about one-half of one per cent. alkali.

DR. BAKER: Is there anyone here who knows about the average life of the average piece of hospital linen, a sheet, pillow-case, or towel; how long should we expect it to live?

Ans. I think it depends on the actual use to which the linen is put. We expect to replace sheets after they have been in constant use three years.

(To be continued.)

Book Review.

Kurzer Leitfaden der Psychiatrie. By DR. PH. JOLLY. 2nd Edition. Pp. 264. Bonn: A. Marcus and E. Webers. 1922.

This small volume on general and specific psychiatry follows in the main the Kraepelinian classification. It is sufficiently condensed to be of value for the student and general practitioner and states in a brief form the recent psychiatric developments. The book is an excellent one for its purpose.

THE BOSTON Medical and Surgical Journal

Established in 1828

Published by The Massachusetts Medical Society under the jurisdiction of the following-named committee:

For three years WILLIAM B. ROBEY, JR., M.D.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

CANCER WEEK.

ALTHOUGH medical records go back over six thousand years, the actual cause of cancer is as little known to-day as it was then, though cancer now exacts a toll of one person out of every ten of those over forty years of age. To prevent disease some knowledge of its cause is implied and of the cause of cancer we are still ignorant. As Americans we have been criticized for our apparent apathy and indifference to matters of health and disease. A large part of this attitude is due to ignorance; ignorance on the part of the public of the early symptoms of disease and of the fatal result which follows when these early symptoms are neglected, and ignorance on the part of the medical profession of the vital importance of early diagnosis and prompt treatment.

The recognition of the immensity of the cancer problem developed a demand for concentrated effort, it demanded organization, cooperation, the collection of accurate data in regard to this disease and the elimination of statistical errors. The American Society for the Control of Cancer has drawn upon the best resources of the country: physicians, laymen, hospitals and medical school facilities. It is organized with state, county and local committees which are engaged in fighting this disease by a campaign of education. In "Cancer Week"

of 1921 it is estimated that ten million people were reached in one way or another with accurate and authorized information in regard to cancer. Such a campaign of health education had never before been attempted; but its success has encouraged the officers of the Society to undertake another "Cancer Week," which will come November 12-18, 1922.

During "Cancer Week" information in regard to cancer will be made available to everyone who may be interested, the signs and symptoms of early and curable cancer will be published, and on the least suspicion of these danger signals the layman is urged to consult immediately the medical advisor in whom he has confidence, his family physician. The medical profession must aid in this dissemination of information and, with this in view, literature dealing with the diagnosis and treatment of cancer in its different situations has been prepared together with numerous clinics, demonstrations and lectures on cancer in the hospitals all over the state.

Early cancer is curable. Late cancer, whether due to ignorance and neglect of the patient or of his physician, can never be cured. Careful and complete histories, and thorough and painstaking physical examinations by the physician first consulted, will help materially to wipe out the disease.

THE ANNUAL TUBERCULOSIS INSTITUTE FOR PHYSICIANS.

OCTOBER 5th and 6th, at the Massachusetts General Hospital, the Boston Tuberculosis Association held its second annual Tuberculosis Institute for Physicians. The first meeting last year was in the nature of an experiment. It proved so successful, however, and seemed to fill a much needed want that it was determined to make it an annual event.

Last year Dr. Lawrance Brown of Saranac Lake and Dr. James A. Miller of New York City, men of international prominence in the tuberculosis campaign, were the two speakers from outside of Boston and this year two men, equally well known, presented scholarly addresses. Dr. Allen K. Krause of Johns Hopkins Medical School, Baltimore, and Dr. H. R. M. Landis of Philadelphia represent all that is best in tuberculosis work.

In addition to this, Dr. Richard C. Cabot of Boston, discussing the "Relation between Physician and Patient in Tuberculosis Work," took up the human side of the subject which is too often neglected nowadays, particularly by the younger men in their search for pure science.

Dr. George B. Magrath, the medical examiner of the City of Boston, in picturesque but in an eminently practical and optimistic vein discussed the pathology of the disease.

Dr. Francis X. Mahoney, Health Commissioner of our city, described the problem from the point of view of the Health Department of the City of Boston.

Dr. Sumner Remick, chief of the Division of Tuberculosis, State House, gave a most valuable talk, illustrated with lantern slides, on the part played by Massachusetts in her care of tuberculosis.

Dr. Cleaveland Floyd discussed the laboratory aids in diagnosis, while Dr. William H. Smith and Dr. Oscar Richardson gave a most valuable and interesting talk on the pathological and clinical relations of the disease.

Dr. Randall Clifford described the work at the new Preventorium for children recently opened by the Boston Tuberculosis Association, and Dr. John B. Hawes, 2nd, and Dr. George Holmes repeated their exercise of last year on the inter-relations between x-ray and the clinical findings in tuberculosis.

A new feature of the Institute this year was a clinic at the North Reading State Sanatorium attended by over 100 physicians. Here after a most valuable address by Dr. E. O. Otis, President of the Massachusetts Tuberculosis League, on the diagnosis of tuberculosis, various well-known experts demonstrated actual patients to small groups of doctors.

In addition to the physicians who attended, there were many nurses and social workers. A welcome, pleasant and not unimportant feature of the Institute was the lunch held on the hospital grounds on the first day and at the North Reading State Sanatorium on the second day.

The Boston Tuberculosis Association feels that the five or six hundred dollars expended last year and again this year for this Institute is money which could not be spent for any better purpose. We agree with the Association in this. We feel that this method of instruction whereby the latest facts in diagnosis, treatment and the general handling of such a disease as tuberculosis are brought home to general practitioners—men who actually come in contact with consumption, particularly in its early stages—might well be applied to other conditions such as the infectious diseases of childhood, genito-urinary problems such as syphilis and gonorrhea, heart disease and others. The Boston Tuberculosis Association in opening its Preventorium for children and in instituting this form of concentrated instruction for physicians and nurses has done valuable work for the health and good of the City of Boston.

REHABILITATION. AN IMPORTANT MEETING.

SOON after the beginning of the war large numbers of men were invalidated back from the front suffering from "Shell Shock." After the United States entered the war and began to

train men in large numbers in the camps, it was found that many men were suffering from "Shell Shock" who had never been under fire or near a shell of any kind. Now it is recognized as never before that many men and women engaged in ordinary industrial life are "Shell Shocked."

In other words, whether there is or is not true "Shell Shock," there is no question but that a great number of individuals, taken away from their home environment and subjected to the strains of military or industrial life, break down under the new conditions to a greater or less extent.

One of the benefits which has resulted from the suffering caused by the war is the greater attention now paid to this class of individuals.

Among the soldiers who have done their bit and have broken under the strain, the problem is one of restoration to health. Among those who have broken down under the strain of industrial life the problem is similar. In the one case the Commonwealth compelled the sacrifice and therefore owes an unquestionable duty. In the other the force of circumstances, usually beyond his control, pushed the individual into a trap from which escape was difficult. The duty of the Commonwealth is not so imperative, but the public good calls not only for the restoration to usefulness of the individual who has suffered, but for the correction of the conditions which caused his fall.

In the solution of these great questions the medical profession must play an important part. The multiplicity of the problems to be met is indicated in the program arranged by Dr. Hilbert F. Day for the General Meeting to be held on the evening of November 22nd at the Boston Medical Library. Preventive Surgical Measures, the Medical and Mental Aspects, the Legal and Industrial Aspects, Occupational and Physiotherapy, and the Care of the Derelicts in our State Institutions are among the topics to be discussed in a series of ten-minute papers by a remarkably able and qualified group of speakers.

Those who wish to see improvement in our Industrial Accident Laws ought to hear what the Chairman of the Board and Mr. Joseph A. Parks have to say. Those who feel that the Commonwealth must do the best possible thing for its derelicts will welcome the suggestions of Dr. John H. Nichols, the head of the great State Hospital at Tewksbury. The presentation of those aspects which more intimately concern the practicing physician and surgeon cannot fail to be of interest to all.

We are face to face with a vast problem, the intricacies of which are just now becoming clear to the public. In the old days on the farm the subnormal individual found a useful place. In modern city life the place has not yet been found. Physicians must help to find it. A civili-

zation which permits the continued breakdown of so many of its citizens is seriously at fault. A large audience should hear the speakers and take part in the discussion. All physicians, whether or not members of the Suffolk District, will be welcomed.

DIPHThERIA SEASON WITH US.

DIPHThERIA, a year round disease, is, however, much more prevalent during the autumn and early winter months. It has been hoped that with the discovery of antitoxin, which is a specific for the cure of this disease, that its morbidity and mortality will reach the lowest level. Unfortunately, it is not so. For the last decade there has hardly been a noticeable reduction in the number of cases of diphtheria in Boston, as well as throughout the United States, and even the mortality has not been as low as was to be expected.

Deaths from diphtheria are due to two causes: first, failure to call a physician until it is too late to administer proper treatment; second, failure of the physician in making the proper and prompt diagnosis and applying the proper treatment, namely, administering antitoxin and in large enough doses.

As for the first, the medical profession cannot be blamed, but there should be instituted a campaign of education among the laity urging the necessity of proper medical advice in all cases of sore throat, even of the slightest form.

As for the second cause, it is entirely up to the physician. All sore throats, or chronic discharges from noses, especially of the bleeding type, should be cultured and said cultures forwarded to a reliable bacteriological laboratory for a proper diagnosis. Typical clinical cases of diphtheria, or suspicious cases, should be treated immediately by the administration of liberal doses of antitoxin, 5000 units to be the minimum, but there should be no hesitancy in giving much larger doses, even as high as 50,000 units in severe cases, and the dosage repeated within twelve hours if the patient does not show marked improvement. Waiting for laboratory findings before the administration of antitoxin in such cases is absolute folly, if not criminal negligence. There is absolutely no harm in giving the patient who is not suffering from diphtheria, antitoxin, for the worst that may happen may be urticaria, which is temporary and harmless; but the failure in the administration of antitoxin, or even in the delay of its administration, may lead to very dire results.

Physicians are, therefore, urged to bear the following points in mind with regard to diphtheria:

1. Urge everybody to be Schick tested so as to determine if they are or are not susceptible to diphtheria.
 2. See to it that all susceptible cases of diphtheria are immunized against the disease by means of toxin-antitoxin inoculations.
 3. Culture of all inflamed throats or chronic discharging noses to rule out diphtheria.
 4. All clinical or suspicious cases of diphtheria should be treated immediately with antitoxin in proper amounts.
- Do not wait for laboratory report in such cases.*
5. Immunize temporarily all possible susceptibles in the household where you have a case of diphtheria, by the administration of immunizing doses of antitoxin.

AN OUTRAGEOUS ADVERTISEMENT.

THE manufacturers of a preparation under the trade name of Zonite have been carrying on an advertising campaign in the daily papers. This compound purports to be a perfected Carrel-Dakin Solution. In the advertisement the claim is made that practically all of the standard antiseptic drugs were comparatively useless as applied to war wounds and exaggerated statements are made of the impotence of surgery before the use of the Carrel-Dakin Solution. The claims made seem to ignore all of the other well-known and efficient means at our disposal for the prevention of the lethal effects of infections. For example, no credit is given to the antitetanic serum, but on the other hand, the advertisement sets forth that Zonite will not only overcome a very large proportion of all forms of sepsis, but may also be used in the treatment of colds, sore throat, diphtheria, pneumonia and the various germ infections.

This remedy is advertised especially for use by the laity, and it is common knowledge that the untrained person is not using good judgment in adopting advertised remedies. Whether this preparation is really a perfected form of the Carrel-Dakin Solution will be known in due time. Furthermore, the original Carrel-Dakin Solution proved beneficial only in certain types of infectious processes and only then when applied with intelligent regard for the principles enunciated by the discoverers. To follow out these principles a special technique was required without careful attention to which good results could not be expected. It would be absurd to suppose that an untrained layman could make intelligent use of such a remedy.

The claims made for this solution are extravagant beyond reason and therefore warrant condemnation. The public should be repeatedly informed that only physicians should be en-

trusted with the responsibility of recommending the treatment of medical and surgical diseases. If the owners believe that it has value it should have been submitted to expert study and thereby have secured its proper place among useful remedies. At present it is in the discredited category of proprietary preparations.

The most serious aspect of advertisements of this kind is that those who heed them and make use of the remedy may be lulled into a false sense of security until the infectious process for which the remedy was applied has advanced to a stage threatening life itself. Diphtheria is amenable to treatment only in the early stage; the same is often true of sepsis. False teaching in these matters, if accepted, must inevitably lead to needless loss of life.

THE INVASION OF MEDICAL PRACTICE BY ILLOGICAL THEORISTS.

OUR sympathy goes out to our New Hampshire brethren because of the shrewd propaganda now being staged by the chiropractors. Under the heading "Instructive, Illuminating, Convincing" half-page advertising is appearing in local papers in our sister State, together with the picture of a handsome masculine person who is spoken of as "the most eloquent exponent of the principles of chiropractic in the world." He speaks of this system as the "Greatest Discovery of the Nineteenth Century."

Perhaps, after the custom of politicians, Abrams may challenge him to a joint debate to settle the question of greatness, for Abrams contends that he is the exponent of the greatest discovery—or the greatest fraud.

The literature of both of these men have some common attributes and seem to be copied, in style at least, from the methods of the circus side-show orators who descend on the marvelous freaks under the canvas. In New Hampshire they have the alluring influence of music in the stage setting.

An illustration of the benefit of chiropractic and the source of the original inspiration is said to have existed in the person of a man who heard a crack in his back which was immediately followed by deafness. Palmer adjusted a lump, heard it crack again and the patient regained his hearing. The lecturer claims that there are 15,000 practitioners in the United States and Canada, and the organization is the second largest health (*sic*) organization in the world and is recognized in 21 States.

Our sympathy for the neighboring State may be tintured with fear of our own downfall, and it may be that New Hampshire is indulging in a sly chuckle over the success of Abrams in inducing practitioners in Boston to accept his theory, and apply his methods.

News Notes.

ROXBURY HOSPITAL.—The Roxbury Hospital at 87 Vernon street was reopened on October 9th. This hospital of fifty beds is one of the Salvation Army institutions. The care of patients has been turned over to Tufts College for teaching purposes and the staff consists of members of the teaching staff of Tufts Medical and Dental Schools. The clinics on Medicine and Surgery are held daily; in Gynecology: Monday, Wednesday and Friday; in Orthopedies, Pediatrics and Ear, Nose and Throat on Tuesday, Thursday and Saturday. The dental clinic is held daily. In addition to the ward beds, which are made use of for teaching purposes, there are a number of private and semi-private rooms.

BOSTON MEN PRESENT PAPERS BEFORE THE NEW YORK ACADEMY OF MEDICINE.—On Oct. 17, 1922, Dr. Reginald Fitz read a paper before the Section of Medicine under the title "Clinical Observations on the Chemical Composition of the Bile," and on Oct. 20 Dr. James Warren Sever read a paper before the Section of Orthopedic Surgery under the title "Treatment of Obstetrical Paralysis."

DEATH RATE IN BOSTON.—During the week ending October 28, 1922, the number of deaths reported was 223, against 191 last year, with a rate of 15.22. There were 36 deaths under one year of age, against 22 last year. The number of cases of principal reportable diseases were: Diphtheria, 52; scarlet fever, 28; measles, 41; whooping cough, 40; typhoid fever, 1; tuberculosis, 32. Included in the above, were the following cases of non-residents: Diphtheria, 4; scarlet fever, 8; whooping cough, 1; tuberculosis, 3. Total deaths from these diseases were: Diphtheria, 5; measles, 2; whooping cough, 5; tuberculosis, 13. Included in the above, were the following cases of non-residents: Tuberculosis, 2.

Dr. James J. Putnam has moved his office to 494 Washington Street, Dedham.

BRISTOL SOUTH DISTRICT MEDICAL SOCIETY.—The semi-annual meeting was held at Odd Fellows' Hall, 141 Rock Street, Fall River, on Thursday, November 2, 1922, at 5 P. M. Reader, Dr. Frank H. Lahey of Boston. Subject, "Clinical Notes on the Diagnosis and Treatment of Gall-Bladder Disease."

ALVARENGA PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about three hundred dollars, will be made on July 14,

1923, provided that an essay deemed by the Committee of Award to be worthy of the prize shall have been offered.

Essays intended for competition may be upon any subject in Medicine, but cannot have been published. They must be typewritten, and if written in a language other than English should be accompanied by an English translation, and must be received by the Secretary of the College on or before May 1, 1923.

Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author.

It is a condition of competition that the successful essay or a copy of it shall remain in possession of the College; other essays will be returned upon application within three months after the award.

NOTES FROM "SCIENCE."—*Science* reports that Dr. Hugh S. Cumming, surgeon general of the United States Public Health Service, sailed on October 5 for Europe to spend two weeks inspecting the government's sanitary stations abroad. While in France, General Cumming will also attend the convention at Paris which is to revise the international sanitary treaty of Rome, where he will present several amendments concerning international measures against typhus, the plague and cholera. He will attend, in addition, the meeting in Paris of the hygiene unit of the League of Nations.

DR. DAVID STARR JORDAN has sailed for Japan. He expects to return to Stanford University in December.

THE LAWRENCE MEDICAL CLUB.—The monthly meeting of the club, which was also the annual meeting, was held on Monday evening, October 23, with Dr. Merrill, at Y. M. C. A. Hall. Chairman for the evening was Dr. Murphy. Subject: "Recent Advances in Diagnosis and Treatment of Heart Disorders," by Dr. Burton Hamilton of Boston.

THE AMERICAN RED CROSS — BOSTON METROPOLITAN CHAPTER — SIXTH ANNUAL ROLL CALL.

On the basis of an essential peace-time service not duplicated by any other social agency, the Boston Metropolitan Chapter of the American Red Cross will seek to re-enlist, on Red Cross Sunday, November 12th, the 300,000 members who supported the organization during the war. Administration has been adjusted to the minimum of efficiency. Every department has been carefully studied, every unnecessary function eliminated.

The main issue of last year's Roll Call—the disabled veteran—is again the main issue of this one. Its importance has merely increased. The peak of the veteran's disability is not yet in sight. Acting, in a sense, as his attorney, the Chapter helps to establish his claim upon the Government. During the process, which is usually involved and always lengthy, the Chapter provides for him and his family a constructive, human and neighborly service that the Government is not equipped to render. This year an average of 1,351 such families was assisted monthly. The war is by no means over for the men who fought it.

Other functions of the Chapter are but relatively less important.

Draft figures, showing 50% of the men examined unfit for duty, made a startling "Stop, Look and Listen" sign on the national highway. The Red Cross heeded the sign. As one of its prime activities in time of peace, it is promoting health through educational and preventive work; assisting communities to establish and maintain health centers, with clinics for infants, children and adults; conducting classes in home hygiene and care of the sick, and life saving. This year 266 persons took first aid instructions; 1180 enrolled in hygiene classes; 204 passed life saving tests.

Through the Volunteer Motor Corps the Red Cross serves those who are ill and in need of transportation to the hospital clinic. Victims of infantile paralysis, children and adults needing hospital care, but not able to travel in street cars or pay for transportation, are conveyed regularly for treatment. More than 5000 invalid soldiers, old people and infantile paralysis patients were transported this year, 35,000 miles being covered in this work. The Chapter also maintains an ambulance, driven by volunteers. This year it responded to 1372 calls.

Volunteers prepared for the Chapter 94 manuscripts, containing more than 4400 pages in Braille—a system of raised letters for the blind. These are sent to the Library of Congress, where they are bound into volumes, and thence to the Evergreen School for the Blind, at Baltimore, for the instruction of the ex-service men.

The Production Department shipped 64,406 garments to refugees overseas. More than 1,157,000 garments have been shipped overseas since August, 1914.

About 70,000 toys, articles of clothing, scrap books and the like were sent to European children by the 130,000 members of the Chapter's Junior Red Cross—not as a charity, incidentally, but as a friendly exchange, for many beautiful and curious gifts, made by the children abroad, were returned. This service is organized through the schools—public, private, parochial—300 of them. Forty-two of these schools are corresponding, via the organization, with schools in

19 foreign countries. The motto of the Juniors is "I Serve." And they do—the ill and handicapped at home as well as their fellows abroad. Who can tell how far-reaching in the promotion of that international understanding and good fellowship—which can alone prevent future wars—this movement to make comrades of the world's children may prove to be?

How many people in New England realize that the Boston Metropolitan Chapter maintains a fully equipped Disaster and Canteen Service, ready for immediate action, with a 100-bed hospital, medical and nursing corps, in the event of a calamity too great for the municipal authorities to handle.

The Chapter has its fingers on the pulse not only of the community, but of a suffering world. It is a mistake to regard the Red Cross as merely a battlefield organization. The disabled veteran, the disaster-stricken, the sick, "the lame, halt and blind," the children of devastated Europe and the children of America, who would like to be shown how to help them—all need "mothering in peace as well as in war." "The Greatest Mother in The World" is a full-time mother—always alert, ready to serve and continuously on her job.

AN EMERGENT APPEAL FOR GARMENTS.

The American Red Cross is launched upon another great international emergency relief operation.

Driven from Asia Minor by the fortunes of war, some half-million refugees have fled for safety to the shores of Southern Europe and the Aegean Islands. They are penniless, homeless, terror-stricken.

The obligation of the Red Cross to meet this crisis brings to members and Chapters a new opportunity for practical service.

Large quantities of garments are needed, which must be prepared with all possible speed; the same type of garments which the Chapters produced for women and children both during and since the war; warm, simple, serviceable clothing, new and second-hand; warm stockings and strong low-heeled shoes. The clothing, if not new, should be cleaned and mended before sending, and the shoes should be in good repair and *tied together in pairs*.

REPORT OF THE DELEGATION OF THE MASSACHUSETTS MEDICAL SOCIETY TO THE ANNUAL MEETING OF THE VERMONT STATE MEDICAL SOCIETY.

Pittsfield, Mass., October 18, 1922.

To Dr. Walter L. Burrage, Secretary of the Massachusetts Medical Society:

In response to the honor conferred upon me by the Massachusetts Medical Society in appointing me a delegate to the 109th annual

meeting of the Vermont State Medical Society, I beg to say that I attended that meeting in Burlington, Vermont, on October 12, 1922. In the evening previous, President Sears of the Vermont Society held a well-attended reception at the City Club. At the annual meeting all the reports of officers and committees were immediately referred to the House of Delegates, as that body has power to take all actions in regard to such reports; so that the annual meeting really transacts no business except through the House of Delegates, which is similar to our Council meetings, although with a very much smaller membership in proportion to the membership of the Society. The secretary had prepared a printed bulletin giving all those reports in full, and these were distributed to the members.

Before the scientific papers were begun the president called upon the visiting delegates. Two of these spoke highly in favor of a group meeting of the New England states. Your delegates were then called upon, and, being the senior, I placed before the meeting the question of the advisability of a large annual meeting including all the state societies. I also suggested that the New England special societies, such as the New England Tuberculosis Society, New England Public Health Society, New England Surgical Society, and similar bodies, should be invited to join in this movement. I suggested that each state society should appoint a committee to meet similar committees from the other states, and possibly similar committees from the special societies, to meet at some central point and discuss the feasibility of such a meeting; suggesting at the same time that it might be a good plan if all the special societies should arrange to hold their annual meetings at the same place and time, and that a House of Delegates should be created with perhaps two or three delegates from each of the special societies and from each of the state societies, and that this House of Delegates should appoint committees for special subjects, such as legislative work, organization work, and educational department. It was suggested that each specialty might hold its sectional meetings and that there should be a few large general meetings. These suggestions were made in order to give the members some idea of the general plan of the meeting, but it was explained that the various committees, when they met, would make the definite plans for the meeting. The whole suggestion was very favorably received by the members, and I was assured by several of them that Vermont would be very glad to take part in such a meeting.

Your other delegate, Dr. Sawyer, added materially to the arguments in favor of such a meeting and talked with many of the members relative to it.

Following this discussion the Society held a scientific session lasting throughout the morn-

ing, and another one in the afternoon, with a meeting of the House of Delegates late in the afternoon. The secretary of the Vermont Society spoke of the great value of interchanging delegates among the state societies and said that it was a custom very much worth while.

I sincerely thank the Society for the honor of representing them as their delegate to the Vermont meeting, and respectfully submit the above report.

A. P. MERRILL.

JOINT MEETING OF THE FOUR WESTERN DISTRICTS.

This meeting was held at the Kimball in Springfield on Thursday afternoon, October 19, 1922. There were about 90 representatives of Hampden, Hampshire, Franklin and Berkshire districts present. Dr. G. L. Gabler of Holyoke, president of the Hampden District, presided. Dr. A. P. Merrill reported for the committee of arrangements and called attention to the proposed annual meeting in Pittsfield. The importance of this change in location was emphasized and the fact brought out that the last annual meeting outside of Boston was in 1878. The organization to arrange for a similar meeting next year was provided for by the election of Dr. A. P. Merrill of Pittsfield, chairman, and H. L. Smith of Springfield, secretary, after recommendation of a nominating committee consisting of Drs. M. M. Brown, M. S. Eisner and Charles Moline.

The announcement was made that Professor S. Burt Wolbach would speak before the Hampden County Medical Society at the November meeting.

Dr. John W. Bartol, president of the Massachusetts Medical Society, was the first speaker. He discussed some of the problems relating to the growth and efficiency of the Society and spoke enthusiastically of the evidence of growing interest in and loyalty to the Society. He felt that the annual meeting of next year in Pittsfield will add to the general usefulness of the Society and assured the members that there would be a large delegation from the eastern part of the state. In reference to the desire to hold the Council meetings outside of Boston, he said that the response to a questionnaire sent to the 18 districts did not thus far indicate a strong desire for this change.

Dr. William H. Robey read an interesting paper on "Observation in Cardiac Diseases." He spoke of the prevailing custom of presenting papers on some features of research work, but he felt that a consideration of some of the interesting phases of an important disease was opportune. In considering the problems often met he strengthened his arguments by reference to his own experiences in treating patients under his care. When the paper appears in

print practitioners will find much of interest and can apply the suggestions presented with profit.

Mr. Henry L. Shattuck, a member of the Legislature and the Massachusetts bar, told of some legislative experiences. He referred to the failure of the Legislature to enact a bill relating to the tuberculin test on cattle, with the explanation that the expense involved was regarded as out of proportion to the anticipated results, and also because of the report that several cattle that had reacted to the tuberculin test were found, after being slaughtered, not diseased. He explained that the midwife bill was rejected because the educational requirements did not seem sufficient to warrant a feeling of security for the mothers to be cared for by these practitioners. He then gave a clear and logical analysis of the features of the Shepard-Towner law and expressed the feeling that it is unconstitutional and would be especially unjust in its application to Massachusetts and several other states.

Dr. W. P. Bowers explained the situation relating to the proposed joint meetings of the several New England state societies. The interest shown seemed to indicate that such meetings have value and it is the wish of the constituent societies that this custom shall be continued.

PLANS FOR CREATING A PERMANENT AND ASSOCIATE STAFF FOR THE NEW ENGLAND DEACONESS HOSPITAL IN BOSTON.

At the regular meeting of the Board of Managers, duly called and held in Committee Room "A" at the Wesleyan Building on March 21, 1922, the following recommendation was made:—

"The Hospital Committee at a meeting held March 20th voted to recommend through the Board of Managers to the Executive Committee the creation of a Hospital Staff. By unanimous vote of the Board of Managers this recommendation was adopted."

This was then brought to the meeting of the Executive Committee, held on Wednesday, March 22, 1922, and the following vote taken:—

"*Voted:* That the recommendations of the Hospital Committee through the Board of Managers that a Hospital Staff be created, be adopted."

After this action had been taken by both the Board of Managers and the Executive Committee it went back to the Hospital Committee for definite action, and at their regular meeting the following month a Special Committee was appointed by the Chairman to formulate some

definite plan for the establishment of a Hospital Staff as recommended. This Committee was made up as follows: Mr. William T. Rich, Chairman; Mr. E. C. Linn, Mrs. H. C. Gallagher, Mrs. Emma H. Watkins, Mrs. F. A. Patterson, the Superintendent, Miss Betts, the Executive Officer, Mr. C. W. Williams.

During the following months considerable attention was given by the Special Committee to the formation of such a Staff, with the result that from the twenty or more doctors practising in the Hospital, four were selected as definitely recommended by the Superintendent, Miss Betts, and her assistants. These were as follows: Daniel F. Jones, M.D., 195 Beacon Street; Elliot P. Joslin, M.D., 81 Bay State Road; Frank H. Lahey, M.D., 638 Beacon Street; F. Gorham Brigham, M.D., 35 Bay State Road.

At the meeting held in the General Office Committee Room by the Special Committee to consider the recommendation of a Permanent Staff every member as above named was present and also, by invitation, the four doctors to be considered for the Permanent Staff. The purpose of establishing a Staff was carefully outlined, and the spirit in which our work in the Deaconess Hospital is done, was fully discussed by the Chairman, Mr. Rich. All of this was unanimously approved by the Committee and the four doctors.

It was then unanimously voted by the Special Committee to present to the Hospital Committee the names of Doctors Jones, Joslin, Lahey and Brigham as being by them selected to form the Permanent Staff of the New England Deaconess Hospital for one year, their duties to commence January 1, 1923. It was also voted to recommend that an Associate Staff be created, this to consist of as many of those now practising in the Hospital as may desire to be on such a Staff and possibly others who may be definitely recommended later.

This action has been taken after months of consideration and from the fact that our increased bed capacity, when the new building is put into use, will demand the standardizing of our institution and the creating of a Staff to meet the requirements of the College of Surgeons. It is a source of great pleasure to the Committee that the four men selected to form our Permanent Staff are all well known to them, two having been with our Hospital almost from its beginning on Massachusetts Avenue. The other two men have a very high standing in their profession and have for several years been serving in our Hospital. The Committee feels that the future of the Hospital will be assured in the leadership of these four men and those who may be associated with them on the Associate Staff.

The above recommendations were unanimously adopted by the Hospital Committee at their meeting on October 17, 1922, and approved

at the regular meeting of the Board of Managers on the same date.

LIST OF DOCTORS INVITED TO BECOME MEMBERS OF THE ASSOCIATE STAFF.

Z. B. Adams, 166 Newbury Street; Arthur Allen, 39 Commonwealth Avenue; Freeman Allen, 200 Beacon Street; Franklin Balch, 279 Clarendon Street; Wm. B. Breed, 402 Marlboro Street; G. W. W. Brewster, 213 Beacon Street; Alice G. Bryant, 502 Beacon Street; Wm. E. Cheney, 377 Commonwealth Avenue; George Clymer, 126 Bay State Road; Robert Cochrane, 86 Bay State Road; H. H. Crabtree, 205 Beacon Street; Arthur A. Cushing, 109 Sewall Avenue; Jas. M. Gallison, 520 Commonwealth Avenue; F. E. Garland, 483 Beacon Street; Harry W. Goodall, 205 Beacon Street; Horace Gray, 32 Fenway; D. Crosby Greene, 23 Bay State Road; Chas. Hare, 483 Beacon Street; E. W. Herman, 23 Bay State Road; A. A. Hornor, 86 Bay State Road; Joshua C. Hubbard, 86 Bay State Road; Henry T. Hutchins, 520 Commonwealth Avenue; Sarah M. Jordan, 638 Beacon Street; Walter Lane, 173 School Street; Chas. Lawrence, 520 Commonwealth Avenue; Geo. A. Leland, Jr., 144 Commonwealth Avenue; H. B. Loder, 520 Commonwealth Avenue; F. B. Lund, 527 Beacon Street; S. F. McKeen, 556 Cambridge Street; Alston; Richard Miller, 402 Marlboro Street; L. B. Morrison, 370 Marlboro Street; Frank Pemberton, 198 Beacon Street; B. H. Ragle, 226 Marlboro Street; Mark Rogers, 483 Beacon Street; Chas. L. Scudder, 144 Commonwealth Avenue; Lincoln Sise, 638 Beacon Street; Geo. G. Smith, 352 Marlboro Street; P. Somers Smyth, 270 Commonwealth Avenue; James S. Stone, 286 Marlboro Street; Louisa Paine Tingley, 9 Massachusetts Avenue; R. S. Titus, 35 Bay State Road; George Tobey, 416 Marlboro Street; Harold Tobey, 416 Marlboro Street; Richard G. Wadsworth, 520 Commonwealth Avenue; Irving J. Walker, 520 Commonwealth Avenue; Franklin W. White, 322 Marlboro Street; Ernest B. Young, 434 Marlboro Street.

BOYLSTON MEDICAL PRIZES.

These prizes, which are open to public competition, are offered for the best dissertation on questions in medical science proposed by the Boylston Medical Committee.

At the annual meeting held in Boston in 1920 a prize of three hundred dollars was awarded to an essay entitled, "Acute Inflammation of the Nose, Pharynx and Tonsils," by Mr. Stuart Mudd of St. Louis.

For 1922 there is offered a prize of five hundred dollars and the Boylston Prize Medal, for the best dissertation on the results of original research in medicine, the subject to be chosen by

the writer. The Boylston Prize Medal will be added to the money prize only in case the winning essay shows special originality in the investigations detailed.

Dissertations entered for this prize must be in the hands of the Secretary, Reid Hunt, M.D., Harvard Medical School, Boston, Mass., on or before February 1, 1923.

In awarding these prizes, preference will be given to dissertations which exhibit original work, but if no dissertation is considered worthy of a prize, the award may be withheld.

Each dissertation must bear, in place of the author's name, some sentence or device, and must be accompanied by a sealed packet, bearing the same sentence or device, and containing the author's name and residence within.

Any elow by which the authorship of a dissertation is made known to the Committee will debar such dissertation from competition.

Dissertations must be printed or typewritten, and their pages must be bound in book form.

All unsuccessful dissertations are deposited with the Secretary, from whom they may be obtained, with the sealed packet unopened, if called for within one year after they have been received.

By an order adopted in 1826, the Secretary was directed to publish annually the following votes:

1. That the Board does not consider itself as approving the doctrines contained in any of the dissertations to which premiums may be adjudged.

2. That, in case of publication of a successful dissertation, the author be considered as bound to print the above vote in connection therewith.

The Boylston Medical Committee is appointed by the President and Fellows of Harvard College, and consists of the following physicians:

Reid Hunt, M.D., Secretary; William T. Porter, M.D., Henry A. Christian, M.D., John Warren, M.D.

The address of the Secretary of the Boylston Medical Committee is Reid Hunt, M.D., Harvard Medical School, Boston, Mass.

EIGHTH ANNUAL REPORT OF THE PETER BENT BRIGHAM HOSPITAL.

The report of the Peter Bent Brigham Hospital for the year 1921 is rather more interesting than the usual run of hospital reports. This is due to the fact that the report is used by the Superintendent and the Chiefs of the Surgical and Medical Services not simply as a vehicle for a few stereotyped remarks, but as a medium for the discussion of some of their problems. One is agreeably impressed by the ungrudging manner in which all of the writers express themselves in regard to the work of their respective staffs. One is led to infer that the spirit of the

hospital is decidedly one of co-operation and mutual support. Dr. Cushing, in his report as Surgeon-in-Chief, objects to the publication in hospital reports of long lists of operations. He suggests that it would be much more valuable if each year the leading hospitals would publish only the statistics of a certain phase of surgery, giving not only the number of operations and deaths, but including end-results as well. In this way, every year some surgical problem would be brought up to date.

Dr. Christian's report brings out the fact that although the cost of labor, of nursing, and of food, has increased very markedly since the opening of the hospital, the salaries of the medical staff have been increased very little. More patients have been cared for, but the increase in medical personnel has not kept up with the demand for their services. He refers to the loss of Dr. Francis Peabody, who resigned as Physician of the Peter Bent Brigham Hospital to become a Visiting Physician to the Boston City Hospital, and speaks of him in the highest terms as investigator, clinician, and colleague.

There are the usual figures dealing with the number of patients treated and with the cost of their care. These figures seemed rather more intelligently arranged than in the average report. They seemed to illustrate some point more clearly. Four thousand three hundred and fifteen patients were admitted to the Hospital in 1921, and there were 15,414 new patients treated in the Out-door Department. The daily per capita cost of ward patients was \$5.82; the cost per visit of out-door patients was 58 cents.

Mr. George Gask, Professor of Surgery at London University and Surgeon to St. Bartholomew's Hospital, took charge of the Surgical Service for two weeks.

The Trustees regretfully report the death of Mr. Walter Hummewell, a Charter Member of the Corporation.

APPOINTMENT OF DR. RANSOM A. GREENE.

Dr. Ransom A. Greene has been appointed Superintendent of the Taunton State Hospital. Dr. Greene was assistant to the Commissioner, Department of Mental Diseases, from February, 1922. From June, 1920 to February, 1922, he was Assistant Superintendent at Danvers State Hospital; August, 1919, to June, 1920, Assistant Superintendent at Gardner State Colony. Previous to this last position he was Captain, Medical Corps, U. S. A., and previous to Army service was for six years senior assistant physician at Monson State Hospital, Palmer, Mass. This extensive service and training brings to the care of the Taunton Hospital one who will undoubtedly continue and promote the usefulness of this institution.

FURTHER INFORMATION REGARDING DR. ABRAMS.

Attention has been called to a letter written by President Wilbur of Stanford University to the Associated Press, a copy of which appears below and which carries a refutation of some statements which have appeared in public:

Oct. 10, 1922.

The Manager, Associated Press, Chicago, Illinois.

Dear Sir:

May I call your attention to the enclosed clippings, apparently sent out from your office, indicating that Dr. Albert Abrams is connected with Leland Stanford University. The same error has been corrected several times. Dr. Abrams has never had any association with Stanford University. He is a graduate of Cooper Medical College, which was taken over by Stanford University long after his graduation. It is evident that Dr. Abrams, or some one associated with his publicity work, has tried to keep up the fiction of his association with Stanford.

It seems to me bad enough for such a responsible institution as the Associated Press to herald far and wide the scientific rubbish of Dr. Abrams, and worse still to connect the name of the University in any way with such absurdities. If there is an opportunity in any later dispatch to correct this misstatement it would be appreciated. Naturally I realize the difficulty of ever following up such a mistake.

I should think it would be clear to the managers of the Associated Press by this time just what kind of a man they are dealing with in Dr. Abrams. Why not give publicity to some of the worth-while things that are being done in this country instead of making American science the laughing stock of the world? With the money and publicity, Abrams' electronic 'bagnesses' of male and female handwriting, and other such stuff, it is naturally confusing to all of those that are not trained in such matters.

I am writing this because I realize that there is a constant desire in the Associated Press to be accurate, conservative and constructive rather than to merely see how many lines of space can be occupied in the papers of the country. Very truly yours,

(Signed) RAY LYMAN WHURR,
President.

ANIMAL EXPERIMENTATION.

Announcement is made below of the program of the Public Meeting to be held in Ford Hall, Boston, by the Suffolk District of the Massachusetts Medical Society, on Sunday afternoon, November 19th. Animal Experimentation will be discussed from the aspect not only of what it has done for Scientific Medicine but also of what Scientific Medicine has done for animals. The list of speakers is itself enough to attract a large audience of physicians and of the public. The subject is one of extreme importance. Massachusetts has been relatively free from the activities of the anti-vivisectionists recently. Last year California had a popular vote on a very drastic bill introduced under the provisions of the initiative and referendum which, if it had passed, would have prevented all animal experimentation and the production of such remedies as diphtheria antitoxin.

The bill was defeated. This year in order to catch the farmer's vote and the hunter's vote the measure is modified to permit operations on domestic animals and to permit the trapping of any wild animals. It seems as if antagonism to Scientific Medicine rather than the prevention of cruelty to animals was the impelling force among those who advocate this measure.

A similar measure is this year proposed in Colorado. The results of these referenda will be known before this article is published.

It has become plain that the influence of the Medical Profession cannot by itself defeat such vicious attempts which, if endorsed, will seriously interfere with the progress of medicine and will deprive the physician of such tried and proved agents as the antitoxin for diphtheria and the serum for meningitis.

The Suffolk District is taking the first step toward educating the public on the matters included in the headings on the program. The time has come when we must rely on popular knowledge rather than on professional authority in combating ignorance and prejudice. Every physician is urged to inform his patients and friends of this very important meeting and to invite them most cordially to be present.

A Public Meeting will be held by the Suffolk District of The Massachusetts Medical Society in Ford Hall, Ashburton Place, Boston, on Sunday, November 19th, at 4 P. M. Charles W. Eliot, President, Emeritus of Harvard University will preside.

What Animal Experimentation has done for	What Scientific Medicine has done for Animals.
--	--

The value of Animal Experimentation to the Physician in his daily work.—Dr. Walter B. H. Parker, Professor of Cannon, Professor of Physiology, Harvard Medical School.	The Benefit to Animals from Medical Experimentation.—Professor George W. Parker, Director of the Zoological Laboratory, Harvard University.
--	---

The Aspect of Antitoxins in Relation to Animal Experimentation.—Dr. Edwin H. Place, Physician in Chief, South Department, Boston City Hospital.	How Animal Experimentation has assisted in the control of Contagious Diseases among Animals. Dr. Foster H. Howard, Director of the Division of Animal Industry.
---	---

What Animal Experimentation has done for Exotic and Tropical Medicine.—Dr. Richard P. Strong, Director of the School of Tropical Medicine, Harvard University.	What Scientific Medicine has done for Farm Animals. Dr. Arthur W. Gilbert, Commissioner of Agriculture of Massachusetts.
--	--

The Public are cordially invited. No tickets will be required.

Correspondence.

COMMITTEE FOR THE PROTECTION OF ANIMAL EXPERIMENTATION.

Mr. Editor:

On December 9, 1921, the Springfield Republican published a letter signed by Mr. French, President

of the New England Anti-vivisection Society. In this letter Mr. French stated that in 1902 and 1903 a long list of public men in those years had signed a petition to the Massachusetts legislature for a law restricting vivisection. Among these men Mr. French included the names of Admiral Van Ryeppen, Butler Ames, Frank A. Day, and F. H. Gillett. The undersigned, on behalf of the Committee for the Protection of Animal Experimentation, immediately wrote to these men and received *emphatic denials* that they had ever supported the A. V. cause.

From Admiral W. K. Van Ryeppen: "I would state that I am not an anti-vivisectionist. I have never written but one letter on the subject and that was in reply to one received from a woman asking me to join in denouncing the cruelty to animals practised by some Washington doctors. I replied that I was opposed to cruelty to animals, but from my acquaintance with Washington doctors I did not believe that it was practised by any of them. This ended our correspondence."

From Mr. Henry B. Day: "I had no recollection of my brother being opposed to vivisection, but I thought I would talk with Mrs. Frank Day before I wrote you. I have now had a talk with her and she says most emphatically that he was not opposed to humane vivisection and in fact believed it is a great means of benefit to humanity. I see no reason why you should not use this statement in any way you see fit."

From Speaker Gillett: "Your letter received. There is not the slightest truth in any intimation by anybody that I am an opponent of vivisection. I have never given any special attention to the subject nor have I ever stated my position as for or against, but I should have to be shown a great deal more than I have been to be against it, and anybody who has made a statement about me has done it absolutely without warrant."

From Mr. Butler Ames: "My brother, Adelbert, calls my attention to a letter from you to him in which I have been put down as a supporter of the Antis. Of course, so far as I know, I have never accepted any such position nor made a statement that might be distorted to that effect. You may use this information as you see fit."

Upon this apparently excellent evidence we discredited Mr. French's assertions, in letters to the *Republican* on December 15 and December 31, and in the Third Statement of the Committee for the Protection of Animal Experimentation. Mr. French has proved, however, that Messrs. Day, Gillett, and Ames did sign such a petition although there is no such evidence in the case of Admiral Van Ryeppen. However, Mr. French states that the Admiral did support the bill in a letter which has now been mislaid or lost.

In justice to Mr. French who has been most patient in allowing us to examine fully into the facts, we must now admit our error and state that we do not accuse him of falsehood.

It is entirely evident, however, that the Committee acted in good faith and the fact that these men at present believe in vivisection is the only point which it is important to establish.

Signed:
T. BARBOUR.
J. C. PHILLIPS.
E. WIGGLESWORTH.

A CORRECTION.

Oct. 28, 1922.

Mr. Editor:

In the *JOURNAL* of October 26, 1922, page 648, there is a squib entitled "The Diphtheria Menace," which I believe that you or any other physician familiar

with the Schick toxin-antitoxin work will want corrected.

Thanking you for your coöperation, I am,
Sincerely yours,

F. X. MAHONEY,
Health Commissioner.

[The error is obvious. The words "when treated with toxin-antitoxin" should have been omitted. The *JOURNAL* has so many times referred to the Schick test and brought out the process of immunization by the use of toxin-antitoxin that we trust the readers will pardon a mechanical error.—Editor.]

Obituaries.

JOHN STANDISH FOSTER BUSH, M.D.

DR. JOHN STANDISH FOSTER BUSH, a retired Fellow of the Massachusetts Medical Society, died at Hartford, Conn., October 20, 1922, at the age of 72.

The son of the Rev. Solon W. and Theoda Foster Bush, he was born in Burlington, Vt., June 4, 1850. He was educated in the Burlington schools and at Roxbury Latin School, his parents having moved to Boston when he was 14 years old. After taking courses at the Massachusetts Institute of Technology he entered Harvard Medical School, graduating in 1874. He served as house officer at the Massachusetts General Hospital and settled in practice in Boston, where he was surgeon to the Boston Dispensary for many years and conducted a large private practice. Dr. Bush was prominent in Masonic circles and was past commander of St. Bernard Commandery, K. T., and later grand treasurer and supreme representative of the Grand Council of the Legion of Honor of Massachusetts. He had lived in Andover and Winchendon since his retirement some ten years ago.

In 1875 he married Miss Josephine M. Mason, who with two daughters survives him.

THOMAS FRANCIS GREENE, M.D.

DR. THOMAS F. GREENE, a prominent practitioner of Roxbury, died at his home following a collapse while touring in western Massachusetts a few weeks ago, on October 24, 1922, at the age of 60.

Dr. Greene was born in New Haven, Conn., had his education at the public schools of that city, came to Boston, and became a proofreader on the *Boston Herald*. In time he entered Tufts College Medical School, receiving there an M.D. in 1894, and settling in practice in Roxbury, where of late he had lived with his brother, Dr. William H. Greene, both Fellows of the Massachusetts Medical Society.

He married Miss Lillian Keeler, who died several years ago. One daughter survives them.

Dr. Greene was connected with St. Mary's Infant Asylum, St. Margaret's Hospital and the Hart Private Hospital, devoting much of his attention to the practice of obstetrics. After

the year 1914 he was a Councilor of the state medical society; in the year 1916 he was president of the Norfolk District Medical Society. He was prominent in the Knights of Columbus, being a grand knight of Rose Croix Council.

Among his memberships were numbered the Catholic Union, the Young Men's Catholic Association, the Franklin Typographical Society, the International Typographical Union, the Boston Lodge of Elks, the Roxbury Historical Society and the American Medical Association.

AMERICAN COLLEGE OF SURGEONS.

New members admitted to Fellowship from the New England States October 27, 1922:

MAINE.

Sullivan L. Andrews, Lewiston; Daniel Alden Barrell, Auburn; Charles Bell, Strong; Sherman W. Boone, Presque Isle; Charles L. Cragin, Portland; Benjamin G. W. Cushman, Auburn; E. Eugene Holt, Jr., Portland; Daniel McCann, Bangor; Frederick W. Mitchell, Houlton.

PROGRAMS FOR HOSPITAL CLINICS DURING CANCER WEEK, NOV. 12 TO 18, 1922.

CARNEY HOSPITAL.

Monday, November 13, 1922.

9:30 A. M.

Gynecological Operations and Demonstrations of End-Results: Dr. F. W. Johnson and Dr. L. E. Phaneuf.

Surgical Operations and Demonstrations of End-Results: Dr. J. T. Bottomley, Dr. D. F. Mahoney and Dr. A. McK. Fraser.

THE PETER BENT BRIGHAM HOSPITAL.

AMPHITHEATRE, OPERATING BUILDING,

10 A. M. to 12 M.,

Tuesday, November 14, 1922.

The Pathology of Malignant Disease in Relation to Age: Dr. Wolbach.

The Treatment of Malignant Disease of the Prostate and Bladder: Dr. Quinby.

Malignant Disease of the Central Nervous System: Dr. Cushing.

Symptomatology of Cancer of the Alimentary Tract and Its Operability: Mouth to Pylorus: Dr. Cheever. Large Intestine and Rectum: Dr. Homans.

Recent Advances in the X-Ray Treatment of Malignant Disease: Dr. Sosman.

OPERATIVE CLINIC DURING THE MORNING.

COLLIS P. HUNTINGTON MEMORIAL HOSPITAL.

Tuesday, November 14, 1922.

Free Special Clinic, 3 to 4:30.

2:30 P. M.

The Cancer Commission of Harvard University.

Dr. R. B. Greenough.

Radium in the Treatment of Disease,

Dr. William Duane.

Cancer of the Skin,

Dr. L. S. McKitttrick.

The State Free Diagnosis Service,

Dr. J. H. Wright.

Cancer of the Buccal Cavity,

Dr. C. C. Simmons.

Cancer of the Uterus,

Dr. G. A. Leland, Jr.

Laboratory Work in Bio-Physics,

Dr. W. T. Bovie.

Radium in the Treatment of Leukaemia,

Dr. G. R. Minot.

radium in the Treatment of Cancer of the Genito-

Urinary Organs,

Dr. G. G. Smith.

The Treatment of Cancer of the Nose, Throat and

Accessory Sinuses,

Dr. D. C. Greene.

THE BOSTON DISPENSARY.

Thursday, November 16, 1922.

9 to 10:30 A. M.

Free clinic to which patients who have or think they have cancer may come for examination and advice without charge.

12 M.

Demonstration of Cases and Methods of Diagnosis, Particularly of Cancer of the Gastro-intestinal Tract: Dr. William E. Preble and associates.

Cancer as an Out-Patient Problem: Dr. Hilbert F. Day.

Cancer of Mouth, Nose and Throat: Dr. Harry J. Inglis.

Cancer to the Pathologist: Dr. William A. Hinton.

Malignancy in the Eye: Dr. Joseph J. Skirball.

Skin Cancers and Their Treatment by Radium: Dr. Henry J. Perry.

X-ray plates illustrating the subject will be on

exhibition in the X-Ray Department (Dr. Hermann N. Osmond).

Light refreshments.

MASSACHUSETTS GENERAL HOSPITAL.

Free Special Clinic, Monday, November 13—2.30.

SURGICAL AMPHITHEATRE,
Friday, November 17, 1922,
10 A. M.

10:00—The Control of Cancer: Dr. R. B. Greenough.
10:15—Cancer of the Skin: Dr. C. J. White.
10:30—Cancer of the Lip and Mouth: Dr. C. C. Simmons.
10:45—Cancer of the Nose and Throat: Dr. D. C. Greene.
11:00—Cancer of the Stomach: Dr. C. L. Scudder.
11:15—Cancer of the Colon and Rectum: Dr. E. P. Richardson, Dr. L. S. McKittrick.
11:30—Cancer of the Breast: Dr. R. B. Greenough.
11:45—Cancer of the Uterus: Dr. Lincoln Davis.
12:00—Cancer of the Genito-Urinary Organs: Dr. J. D. Barney.
12:15—The X-Ray Therapy of Cancer: Dr. G. W. Holmes.

BOSTON CITY HOSPITAL.

CHEEVER SURGICAL AMPHITHEATRE.
Saturday, November 18, 1922,
10:30 A. M. to 12 M.

In coöperation with the Cancer Week Campaign of the American Society for the Control of Cancer, the following symposium will be held in the Cheever Surgical Amphitheatre. Physicians, students and nurses are welcome.

The Pathologist's Conception of Cancer: Dr. F. B. Mallory.

Early Recognition of Uterine Cancer: Dr. R. M. Green.

Röntgen Differentiation of Gastric Malignancy and Chronic Ulcer: Dr. F. P. Butler.

Prenatal and Early Malignant Skin Lesions: Dr. T. W. Thorndike.

Symptoms Suggesting Concealed Malignancy: Dr. R. C. Larrabee.

Detection of Malignancy of the Genito-Urinary Tract: Dr. H. B. Howard.

Radium and X-Ray: Indication for Their Use: Dr. Herman Osgood.

Surgical Procedures for Removal of Malignant Growths: Dr. Halsey Loder.

JOINT MEETING OF THE NEW ENGLAND ROENTGEN RAY AND NEW ENGLAND LARYNGOLOGICAL SOCIETIES.

These societies will meet on November 10 next at the Boston Medical Library. Papers will be presented by Dr. Charles S. Stokes of New York City and Dr. W. D. Witherbee of New York City. Refreshments will be served after the meeting.

A. S. MERRILL, M.D.,
Secretary, N. E. Roentgen Ray Society.

WOMEN FOR SHEPPARD-TOWNLE BILL.—The Maine League of Women Voters has, according to the papers, adopted a resolution favoring the Shepard-Townle Bill. The Governor has placed himself on record as opposing this measure.

Dr. Oscar M. Schloss will speak on Ketosis in Infants and Children in the Section of Pediatrics, N. Y. Academy of Medicine, Nov. 9, 1922.

HARVARD MEDICAL ALUMNI ASSOCIATION.

NOTICE OF MEETING.

The Council of the Association, at a meeting held on October 31, 1922, has voted to call a regular meeting of the Association for Monday, November 20, in the faculty room of the Harvard Medical School, at 12.30 P. M., for the purpose of acting upon the following recommendations passed by the Council, to wit:

1. "That Section 1, Article III. of the constitution be amended to read that 'Each graduate of the Harvard Medical School shall become *ipso facto* a member of the Harvard Medical Alumni Association.'"

2. "That Section 4, Article III. be amended by adding the following sentence: 'All members of the teaching staff of the Harvard Medical School shall during their term of service be considered honorary members of the Harvard Medical Alumni Association.'"

FRANCIS M. RACKEMANN, M.D., Secretary.

SOCIETY MEETINGS.

DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District:—Hyannis, February 2, 1923, (Annual Meeting)—May 4, 1923.

Bristol South District:—Fall River, May 3, 1923.

Essex North District:—Haverhill, (Semi-Annual Meeting)—Jan. 3, 1923. Y. M. O. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Suffolk District:—Combined meeting of Boston Medical Library and Suffolk District, November 22, 1922; December 27, 1922; January 31, 1923; February 28, 1923; March 23, 1923; Annual Meeting, April 25, 1923.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Hist. The date for each speaker has not been assigned.

Middlesex North District:—Meetings; Wednesday, January 31, 1923.

Worcester District meetings in Worcester, Dec. 13, 1922, Jan. 10, Feb. 14, March 14, April 11 and May 9, 1923, the last named date being the annual meeting.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

November, 1922. Massachusetts Society of Examining Physicians, (Date and place of meeting undecided), Hilbert F. Day, Secretary. National Cancer Week, November 12 to 18.

November 16, 1922. Joint meeting of the New England Roentgen Ray Society and the New England Laryngological Society at the Boston Medical Library.

December, 1922. New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

December 26-30, 1922. American Association for Advancement of Science meets in Boston.

January, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston, W. H. Allen, Mansfield, Mass., Secretary.

February, 1923. New England Dermatological Society Meeting, February 14, 1923, at 3.30 P. M., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

March, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary.

April, 1923. New England Dermatological Society Meeting, April 11, 1923, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston, W. H. Allen, Mansfield, Mass., Secretary.

May, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided). American Pediatric Society Meeting, May 31, June 1 and 2, 1923, at French Lick Springs Hotel, French Lick, Ind., H. C. Carpenter, Secretary.

June, 1923. American Medical Association, San Francisco, June 25-29, 1923, Alexander B. Craig,* Chicago, Ill., Secretary.

July, 1923. Massachusetts Association of Boards of Health, July 26, Nantasket, W. H. Allen, Mansfield, Mass., Secretary.

*Deceased Sept. 2, 1922.

SUBPHRENIC ABSCESS.*

BY HOWARD M. CLUTE, M.D., F.A.C.S., BOSTON,
Assistant Out-Patient Surgeon, Boston City Hospital.

A CONDITION which is the complication of a preceding disease possesses an unusual interest. A complication that may follow any abdominal surgical lesion, whether common or rare, demands attention; a complication that is seen but seldom must be recalled to memory lest it be overlooked on the rare occasions of its presence; a complication that when diagnosed offers large opportunity for cure is worthy of careful study. These three aspects appear in the condition known as subphrenic abscess.

Subphrenic abscess is rarely, if ever, a primary disease, but is secondary to an infective process elsewhere in the body. This infection is commonly in the abdomen, rarely in the thorax. Surgical literature of today reveals this complication much less frequently than the literature of fifteen years ago, no doubt because the modern surgical principles of drainage account in part for this improvement. The condition is found most frequently after the perforation of an ulcer of the stomach or duodenum. Appendicitis is second in the list of frequent causes. Other and less common factors preceding subphrenic ab-

cess are: disease of the gall-bladder and biliary tract; disease of the pancreas, the spleen, and the liver; empyema; wounds of the abdomen and chest; soiling of the abdominal cavity at operation; and septicaemia with localization of infection between the diaphragm and the liver.

The situation of the abscess on the under surface of the diaphragm depends upon (1) the preceding inflammatory process, and (2) the anatomical relations of the liver and the diaphragm. Save for the "uncovered area," posteriorly, the surface of the liver is entirely covered with peritoneum. From the margins of this uncovered area on the right lobe are reflections of peritoneum running to the diaphragm, called the coronary ligament. The right extremity of this coronary ligament has been called the right lateral ligament. The left lateral ligament is a fold of peritoneum running from the upper posterior surface of the left lobe to the diaphragm. The coronary ligament and the left lateral ligament divide the diaphragmatic surface roughly into an anterior and a posterior half. This division is completed by the other peritoneal reflections in this area which form the gastro-splenic omentum and the phrenocolic ligament. A little to the right of the midline of the anterior abdominal wall, the falciform ligament arises. This fold of peritoneum is attached to the diaphragm and passes to the anterior and superior faces of the liver. On the upper aspect of the liver surfaces the two layers of the falciform ligament separate. The right layer passes into the coronary ligament and the

*An illustration of this insidious type was the case of a soldier who sustained a perforating bullet wound of the abdomen. He had no difficulty until two weeks later when he developed fever of increasing severity. He was operated upon by the technique here described and discharged cured.

left layer into the lateral ligament. The falciform ligament thus divides the anterior and superior peritoneal faces of the liver into right and left halves.

This arrangement of peritoneal reflections produces four fairly distinct potential spaces between the liver and the diaphragm which are

FIG. 1. Drawing showing anatomical relations of abscess in right anterior subphrenic space. (a) represents a small collection of serous exudate in pleural cavity; (b) the diaphragm. Note elevation of diaphragm on right with resulting compression of lung.

(Sketch adapted from "Toldt's Atlas of Anatomy.")

lined by peritoneum. There is only one space, called the "uncovered area" of the liver, in which the liver and the diaphragm are in contact without the interposition of peritoneal surfaces.

The boundaries of these four intraperitoneal spaces are as follows:

The right anterior space has the right lateral and coronary ligaments behind; the upper surface of the liver below; the falciform ligament to the left and the diaphragm above.

The left anterior space has the left lateral ligament behind, the diaphragm above. To the right is the falciform ligament, the stomach and the gastro-hepatic ligament. To the left is the abdominal wall and the spleen.

The right posterior space is sometimes termed the right subhepatic space or right kidney pouch. It is bounded above by the liver, the gall-bladder and the right lateral and coronary ligaments. Posteriorly is the diaphragm. To the left is the margin of the gastro-hepatic omentum and the foramen of Winslow.

The left intraperitoneal space is the lesser peritoneal cavity.

Drainage into one of these spaces is favored by gravity when the patient is lying supine in bed. The products from a perforated gastric ulcer tend naturally to collect in the right an-

terior space. A high lying appendix abscess tends naturally to drain into the right posterior space by way of the lateral colic groove. An ulcer of the posterior surface of the stomach may perforate into the left posterior space. The lymphatics behind the cecum and ascending colon pass upward into the subphrenic area. Infection may readily follow this route.

Barnard pointed out years ago that there was a communication between the lymphatics in the region of the deep epigastric artery with the falciform ligament which leads to the subphrenic region. There may, of course, be abscess formation from the presence of an infection in the blood stream. A pyelphlebitis may occur and present as one of its features an abscess about the portal vein just below the diaphragm.

The onset of symptoms of subphrenic abscess may be insidious or stormy. In the cases we have seen, the first sign of approaching trouble has been a steadily rising daily fever with no local evidence of the cause. The patient is convalescing fairly well from a surgical lesion of the abdomen when his chart assumes the so-called "picket fence" appearance. Chills and sweats may accompany the daily rise in temperature. He now loses ground rapidly. His appetite becomes capricious or is absent. His face is drawn and haggard. He loses weight very rapidly. He complains of a sense of discomfort or fullness in the epigastric region. It may be impossible for him to draw a deep breath. Cough and hiccough are present in a great many cases. Pain with deep breathing is a frequent accompaniment of the early stages of the disease from the presence of a diaphragmatic pleurisy. There is frequently considerable gastric distress with belching of gas and sour eructations. Constipation is sometimes marked; diarrhoea is rare. In general, the patient looks and feels very sick, but has little or nothing on which to base his complaints.

Occasionally the onset is much more acute. This is especially prone to happen with a perforation of the stomach or duodenum, which suddenly floods the subphrenic area with irritating products. Here the initial shock and collapse is due to the perforation. The outcome may be a diffuse peritonitis or a localized subphrenic collection of pus with symptoms such as we have set forth.

The physical signs in such a case will vary, first with the situation of the abscess, and second with the type of abscess. There are two types of abscesses. One, containing fluid (pus) alone; the other, containing pus and gas. The gas may come from the lumen of a viscus or from the fermentative activity of anaerobic bacteria present in the pus. We have seen two cases with pus alone and one case with pus and gas. In general, inspection reveals marked limitation of motion of the affected side of the chest. There may be visible widening or bulging of the right lower thorax. Edema of the side or back of the chest may occur. Percussion will reveal flatness over

FIG. 2. X-ray in supine position of Case 3. Note diaphragm high and smoothly rounded on right. Gas bubble not visible in this position. (X-ray with portable machine by Dr. Frank Wheatley.)

the lower chest in front and in back if the abscess contains pus alone. The presence of gas in the abscess cavity will give a tympanitic note to percussion with obliteration of the lower liver dullness. The dullness may extend anteriorly as high as the second rib and posteriorly to the middle of the scapula. Often the line of percussion dullness will descend with deep inspiration quite perceptibly.

Auscultation will reveal absent breath sounds and absent vocal fremitus up to the limit of dullness. Above this level, however, both vocal and tactile fremitus may be slightly increased for a limited distance due to the margin of compressed lung next to the high diaphragm. Occasionally a pleuritic friction rub may be heard over the collection of fluid, but this is not found constantly. When there is gas in the abscess cavity, a succussion splash may be obtained by shaking the patient.

The occasional presence of a varying amount of fluid in the pleural cavity renders the diagnosis more difficult. Simple or purulent pleurisy is frequently diagnosed in these cases. An exploratory needle puncture may be a valuable

aid to diagnosis. It should, however, be done with great care. We may obtain clear straw-colored sterile fluid from the pleural cavity and then when the needle perforates the diaphragm and enters the abscess we find gas and pus entering our syringe. Sterile fluid followed by pus at the same tap is almost pathognomonic of subphrenic abscess.

Palpation may reveal the liver border well below the costal margin. Compression of the chest wall low down or strong "flist percussion" may cause pain. A well marked leucocytosis is generally present though in certain chronic cases there may be a leucopenia.

Very often the diagnosis of subphrenic abscess can be finally made only by x-ray, which offers us the most positive findings in the majority of cases. By the symptoms and physical signs alone, it may well be impossible to determine whether we are dealing with a subphrenic abscess, a pyothorax, or a pyopneumothorax. X-ray plates and fluoroscopic examinations will generally settle the question definitely.

Normally the right diaphragm is one-fourth to one-half inch higher than the left. Each side

FIG. 3. X-ray of CASE 3, in sitting position. Note persistent high diaphragm on right; straight line level of the pus in the abscess with gas above it. (X-ray with portable machine by Dr. Frank Wheatley.)

moves straight up and down with respiration and there is no flattening of the curve. The normal range of this motion is one-half to three-fourths inch, with quiet breathing, but with forced respiration the range increases to two and one-half or three inches.

Any inequality or fixation of these movements is pathological. In subphrenic abscess we find the diaphragm on the affected side raised and fixed. It does not move with respiration to any degree, while the unaffected side maintains its normal range of motion. The lung above the fixed diaphragm is compressed. The level of the diaphragm may be only slightly raised, or it may reach up to the third rib. The costo-phrenic angle is not obliterated as it is with thoracic collections of fluid.

The line of the diaphragm is a smooth and regular curve, involving the entire course of the affected side. In liver tumors, liver abscesses and adhesions from old pleurisy, this curve is more irregular and localized more sharply to a single area of the diaphragm. A high, fixed diaphragm with a persisting costo-phrenic angle is very typical of subphrenic abscess.

The course of the disease is marked by steady decline. Weight loss is generally very pronounced, as are the weakness and general debility. Without operation, the mortality varies from 82% (Eisendrath quoted by Locky *et al.*) to 100%. Death results from the effects of the long continued toxemia or from rupture of the abscess into some neighboring viscus. With

operation, the mortality is about 25% of the total cases.

The treatment of subphrenic abscess is incision and drainage. The anatomical location of the abscess, however, should be carefully considered, for this will determine the method of approach. Abscesses on the left side must always be first approached from the front. In the left anterior space, drainage must be instituted through the anterior abdominal wall. If the left posterior space is found to contain pus, the anterior incision should not be used; but a second incision should be made to approach the collection from behind. This may or may not be below the rib margin. Collections of pus on the right side are drained either (1) from below the rib margins; (2) by incision between the lower ribs; or (3) resection of one or more ribs.

The situation of these abscesses is such that to drain them adequately we must either go through the lower part of the pleural cavity, or we must retract the pleura and go around it. Great care must be taken, in either case, that the pleural cavity is not laid open to the possibility of infection from the abscess. An empyema superimposed on patients already so ill may readily prove fatal.

It is our belief that the drainage of these abscesses should be carried out in two stages. We have done the entire two-stage operation under local anesthesia once, and once with ether for the first stage and novocaine for the second. An incision is made along the center of the

FIG. 4. X-ray in sitting position of CASE 3, 3½ months after operation. Note that right diaphragm still remains high and limited. (X-ray by Dr. Frank Wheatley).

tenth rib, in the mid-axillary line, for a distance of two and one-half to three inches. This portion of rib is now removed and the pleural cavity is opened by an incision parallel to the rib and in the center of its bed. It may be well to pass a suture about the intercostal vessels which are exposed. In one case we cut these and found no anesthesia necessary for the second stage of the operation. The pleural cavity may contain a little straw-colored fluid, which will flow out of the wound. The diaphragm, covered by its layer of pleura, presents in the wound a close approximation to the cut parietal pleura. The borders of the incision in the parietal pleura are now sutured to the diaphragm with a continuous catgut suture. Sterile vaseline is put into the wound and a dry sterile dressing applied. This completes the first stage of the operation. The operator may, before leaving the wound, insert a needle through the diaphragm to locate the abscess, if he so desires. It is better, however, to leave the abscess entirely alone for forty-eight hours after the first stage and thus permit the pleural cavity to be fully walled off by adhesions. The second stage of the operation is relatively simple. Under local anesthesia, unless the intercostal nerve has been cut and the area rendered insensible, an incision is made in the diaphragm parallel to the incision in the parietal pleura.

operation. Wounds now entirely healed and patient feels perfectly well. Note that right diaphragm is still very high. By fluoroscope the excursion of right diaphragm is still very

The edges are retracted and a finger inserted in the direction of the abscess will shortly disclose the presence of pus. A large rubber tube is inserted and held in place with a suture through the skin or fascia.

It is advisable to continue this tube drain for a week or more in large-sized abscesses, and to replace it gradually with rubber dam. Too hasty withdrawal of the tube may result in a secondary local collection of pus.

With this method of drainage, the temperature has rapidly come down to normal in our cases and has remained there. We have had no difficulty from bleeding from the intercostal vessels or from necrosis of the cut rib. We believe that the two-stage operation is safer than the one-stage procedure because it reduces to a minimum the chance of empyema.

CLINICAL NOTES ON THE DIAGNOSIS AND TREATMENT OF GALL-BLADDER DISEASE.*

BY FRANK H. LAHEY, M.D., BOSTON.

THE types of pain which can occur in gall-bladder disease are numerous, varying from the typical severe colic, which is referred in a characteristic way, to a very moderate localized and constant pain. Between these two types there are all degrees of variation.

With a fairly normal gall-bladder containing numerous very small stones, the degree of pain is often almost in proportion to the size of the stones, the very small stones of the size of bird-shot passing through the ducts with pain of only the slightest intensity and of short duration, while stones which are too large to pass the cystic duct may be of proper size to become wedged in the pelvis of the gall-bladder and produce pain of the typical colicky character. It is our opinion that the typical colicky pain is more prone to occur in a patient whose gall-bladder walls are but little involved pathologically.

It is in the old gall-bladders whose walls are thickened from long-standing cholecystitis that the pain of constant type is prone to occur. In this type of gall-bladder disease, there is frequently obstruction in the cystic duct as the result of either stone or exudate and the gall-bladder, distended and thick-walled, contains at times purulent material and at other times merely thick, viscid mucus unstained or only faintly stained with bile, in either case with or without the presence of stones. It is in this type that the pain is apt to be of the constant and persistent variety.

The severity of the pain and, at times, the suddenness of relief have been significant points in the history associated with this disease, sudden relief of colicky pain indicating the slipping back of the stone from the pelvis of the gall-bladder.

Upon the history of soreness over the gall-bladder region after the pain has ceased we

have also come to depend as being quite indicative of the presence of this disease.

The location of the pain and tenderness has been atypical in many cases,—sometimes in the right lower quadrant with a prolapsed liver, at times to the left of the midline, although in these cases the gall-bladder was demonstrated to be in its normal location. There have been several cases also in which the pain and tenderness have been located so far out to the right as to be almost in the loin. Unlike the above cases, these gall-bladders have been demonstrated at operation to be located far out to the right where the pain and tenderness existed.

As to the reference of pain, there has been but little consistency. In many cases the pain has not been referred at all; in others it has been referred to the left shoulder; in many, straight through to the back, and in the remainder, typically to the right shoulder.

In cases operated early, before the attacks have become frequent, the past history usually contains the story of the occurrence of acute indigestion. It is surprising how often this diagnosis is still made.

The occurrence of jaundice is found in the past histories of those cases where the common duct is involved in only a small percentage of all cases. In our opinion it is desirable that cases should be operated upon, if possible, before jaundice occurs, inasmuch as its presence indicates in every instance one of two very undesirable features: stone in the common duct or infection spreading to the common duct.

Tenderness has been found to vary according to the relation of time of examination to time of attack. Several cases, however, have failed to show tenderness, even immediately after an attack, probably because of the fact that the attacks were largely due to mechanical obstruction without attendant infection.

The diagnostic value of tenderness, unless well marked and definitely demonstrable, is materially modified by the fact that some gall-bladders are located high under a shelving edge of the liver, making palpation difficult and uncertain, as well as by the fact that deep palpation elicits tenderness in many patients in whom no lesion can be demonstrated.

In inflammatory lesions of the gall-bladder, spasm is remarkably often absent—even in those lesions which verge upon gangrene. Likewise marked reactions of temperature are strikingly rare in a definite number of cases, this factor being dependent, of course, upon the degree of cholecystitis present.

X-ray in our opinion is of value only as positive evidence. We are unable to state in what percentage of cases the shadow of the stones has been demonstrated, but we have had a sufficient number of undemonstrated cases to make us willing to operate on those cases with definite histories but negative x-ray findings.

We have published our views as to the value of inferential x-ray evidence in gall-bladder

*Read before the Grafton and Belknap Clubs, Boston, of the New Hampshire Medical Society on June 17, 1922. — W. W. W., S. H.

disease such as demonstrable gall-bladder, flattening of the duodenum and fixation of the duodenum to the right. We believe that operation should be urged with such evidence, not upon the basis of the x-ray findings but upon the clinical history and findings, and that x-ray findings of the above sort are of value only as corroborative evidence and should never in themselves be considered decisive factors in favor of operation.

We therefore feel that the only x-ray evidence which in itself is diagnostically dependable is the definitely demonstrable shadow of the stone upon the plate, and by this we mean that the shadow or shadows must be of sufficient clearness that we ourselves can see them.

Regarding the method of diagnosis by means of the duodenal tube, based upon the findings of Meltzer that the introduction of magnesium sulphate into the duodenum produces relaxation of the sphincter of Oddi, the sphincter at the junction of the common duct, and also contraction of the gall-bladder (law of contrary innervation), we have very marked reservations.

The method consists in the introduction of the duodenal tube, care being taken that teeth are brushed, the mouth cleansed, and the throat gargled with an antiseptic, and the instillation of 50 c.c. of 33 1-3 per cent. magnesium sulphate, collections of bile being made from time to time. A microscopic study of this material is made. The first bile, light yellow in color, is considered common duct bile; the second, darker and more viscid, gall-bladder bile; the third, thin and yellow, fresh liver bile.

As a method of diagnosis, certainly in severe cases, we feel that the possibility of error, both in obtaining bile and interpreting the evidence thus obtained, is so great as to render it of value only as confirmatory data. It is our feeling that we would not hesitate to proceed surgically in spite of negative evidence of this character, clinical signs being present; while we would hesitate to proceed surgically upon positive evidence of this type, clinical signs of convincing character being absent.

The medical treatment of gallstones today, except in those patients who are too old or too weak for surgery, has very few surviving adherents in this country. Its popularity is probably still retained to some degree in Europe, where the enthusiasm for Spa treatment is very much greater than in this country. All measures of this nature must of course be directed largely to increasing elimination and lessening the burden of digestion, and should not be aimed directly at the stones or the pathological process within the bile passages secondary to them. An exception to this, of course, is the so-called internal drainage spoken of above, under the head of diagnosis. We consider this method even less adequate as a therapeutic measure than as a diagnostic measure. We be-

lieve that the amount of drainage accomplished is uncertain, and that even though the ducts be drained, an infected gall-bladder may be and usually is present, entirely undrained and menacing the life of the patient by the possibility of rupture or sepsis.

If it be accepted, then, that operative measures are in general indicated in gall-bladder disease, several important queries at once arise. First, should we advise operation for quiescent gallstones discovered in the course of other x-ray examinations? To this query we reply affirmatively. We urge their removal even though no other operative measure is contemplated, first, because it has been impressed upon us in our experience that gallstones often remain quiescent throughout middle life only to produce symptoms at an age when the individual is a very poor operative risk; second, because we are convinced that gallstones which are sometimes considered quiescent are often responsible for mild but persistent digestive disturbances without definite attacks of gallstone colic. The fact that carcinoma of the gall-bladder occurs but rarely in gall-bladders not containing gallstones adds, we believe, a further argument to the logical indications for the removal of gallstones. Furthermore, we believe that operation should be urged in cases of quiescent gallstones, first, because mild or acute pancreatitis is at all times a distinct possibility in the presence of gallstones; secondly, because common duct stone with its decided increase in mortality rate over stones in the gall-bladder is always a possibility; and finally, because of the danger of cholangitis with its usually fatal outcome.

The second query which arises is, should we advise operation during the attack, or should operation be deferred until the attack has subsided? We believe that immediate operation should be urged, first, in those early cases (largely mechanical in nature) where there have been but few previous attacks, where a fairly normal gall-bladder is presumed to exist, and where there is no evidence of infection, such as temperature and white blood count reactions; and, secondly, in those cases in which an attack is complicated with acute cholecystitis, particularly with high fever.

In the first group we urge immediate operation because the problem is largely a mechanical one, uncomplicated by infection. In these cases relief from suffering can be given the patient at once, with no added danger, and the possibility of a stone making its way into the common duct and necessitating the further procedure of choledochectomy is diminished.

In the second group of cases we urge immediate operation because with cholecystitis it is impossible to prophesy whether the process will go on to resolution or progress to slough and gangrene of the gall-bladder or infection of the ducts.

In the less severe type (showing mild infection with moderate temperature reaction) of long standing and with repeated attacks, we feel that operation may with safety be deferred until cholecystectomy can be done upon a gall-bladder whose walls and particularly whose cystic duct and periductile tissue present less induration and oedematous tissue, thus permitting more accurate dissection with less danger of disseminating infection and later crippling adhesions.

Common and hepatic duct stones we feel should be operated at once, unless contraindication exists in the form of obstructive jaundice, in which emergency every effort should be directed toward reducing the coagulation time to its lowest possible point. Operation should be undertaken in these cases before the occurrence of cholangitis and before the occurrence of cholangitis with its unfavorable post-operative prognosis.

We have seen the coagulation time in obstructive jaundice as high as thirty-six minutes. In obstructive jaundice we do not believe that it is justifiable to operate without attempting materially to lower the coagulation time. We have recently seen a fatal outcome due to post-operative hemorrhage in two cases of this character operated elsewhere than in our clinic, no attempt having been made preoperatively to reduce the coagulation time by suitable measures.

We consider a coagulation time of ten minutes or under within the limits of safety. Calcium has for many years been employed as a measure suitable for increasing the coagulability of the blood and probably in most instances has had little if any value in this respect except in the condition of obstructive jaundice, where it appears to have real value, producing a definite and demonstrable diminution in the coagulation time. We have used it in the form of calcium lactate by mouth and, where its continued use has produced gastric disturbance, by rectum. Given by mouth or by rectum, large doses are necessary to become effective,—twenty to thirty grains three times a day. It has been our experience that when the drop in coagulation time has been accomplished, it may be of but very short duration and operation should be undertaken at once.

We have recently had prepared for us by Hynson, Westcott and Company 5 c. c. tubes of sterile 10 per cent. calcium chloride solution which may be given intravenously, by means of which lowering of the coagulation time may be accomplished much more quickly and without the nausea which frequently attends the administration of large doses of calcium by mouth. It should be given once a day for three days, together with calcium lactate by mouth, if tolerated.

The operative technique of cholecystectomy needs no elucidation, in our opinion. We do, however, feel that the decision as to whether we should employ cholecystectomy or chole-

cystostomy in certain cases is a very important one, and we have formulated the rule that we do cholecystostomy in those cases of gall-bladder disease in which the gall-bladder is too good or too bad to take out, and in certain obese individuals in which the difficulties of the procedure of cholecystectomy make its risks outweigh the gain to be attained. The first class are those rare cases in which a single smooth stone exists in a gall-bladder quite normal to inspection and palpation, and even in such cases we frequently do cholecystectomy, except in the corpulent individuals above mentioned.

We hold particularly firm convictions concerning the indication for preliminary cholecystostomy in the latter group—that is, in the gangrenous gall-bladder too bad to take out—for the reason that cholecystectomy in a thick-walled and acutely infected gall-bladder (we do not refer to the thick-walled and distended gall-bladder without infection) presents not only technical difficulties of removal, but serious possibilities of immediate and remote post-operative complications. It is in this type of case that removal of the gall-bladder is often accomplished with difficulty, removal being many times possible only by dissection of the indurated bladder from the fundus toward the cystic duct and accompanied often by considerable bleeding and rupture of the gall-bladder with dissemination of infection. It is in this type of case that oozing surfaces are often left in the bed of the liver previously occupied by the gall-bladder, requiring the introduction of gauze packing to control them. These are conditions favoring distinctly the occurrence of an infected hematoma in the right upper quadrant as an immediate complication, and crippling peripyloric adhesions as a remote post-operative complication, both of which dangers may be obviated in this type of case by preliminary cholecystostomy.

We have therefore based our opinion as to the removability of the gall-bladder upon the probable degree of post-operative infection in the defect left by its removal and the probable amount of peripyloric adhesions.

Our decision as to whether the removal of the gall-bladder (that procedure having been decided upon) shall be accomplished from the cystic duct upwards or from the fundus downwards has always been based upon the adequacy of exposure of the cystic duct at its junction with the common duct. We decidedly prefer and advocate the former procedure, but from our experience have firmly fixed convictions that the primary dissection and ligation of the cystic duct should never be attempted except where very adequate exposure of that structure, of the common duct, and of the cystic artery is possible. In all cases where this is impossible, we feel sure that dissection from the fundus downward until the gall-bladder hangs by the cystic duct is infinitely safer, both as regards preservation of the intactness of the common

duct and control of the cystic artery. It is also our firm conviction that the cystic duct should never be cut and tied until it has been carefully wiped down to the common duct and the latter structure carefully identified as outside of the grasp of the right angle clamps.

Regarding exposure of the cystic duct and cystic artery, we wish to call attention to the frequent unusual location and relation of these structures. We have several times seen a cystic duct lying parallel with the common duct and emptying into that structure not at the usual location but well down and close to where the common duct enters the duodenum. In such a case we removed a stone from the parallel-lying cystic duct, thinking it to be the common duct, and were greatly distressed to be unable to pass a probe up into the hepatic duct until further dissection revealed the fact that the stone had been removed from an elongated cystic duct and that the common and hepatic ducts had not been opened at all.

We have seen the cystic artery come from behind the hepatic duct. We have seen it, of course, in its usual location close to the cystic duct and at times at a distance from the cystic duct where it is overlooked and easily injured. In this connection we know of no operative complication that is more trying than a torn cystic artery in a deep field, difficult of exposure and rapidly filling with blood each time after being wiped out.

As to common duct drainage, we have no rule except to explore all large common ducts and to pass a probe through any of which we have the slightest doubt. A very good procedure we have found is to pass a catheter through the common duct until it enters the duodenum. Salt solution is then injected through the catheter and if it passes the sphincter into the duodenum, demonstrating the absence of obstruction in the duct, water will not return around the catheter; if it does not pass into the duodenum, water will pass back around the catheter.

We do not approve of the closure of the abdomen without drainage. We admit having had cases in which the ligature has come off the cystic duct even after the most painstaking application. We admit having left a stone in the common duct after removal of the gall-bladder, and as long as such possibilities may arise (they do in every surgeon's experience), and we see no way to be certain that they may not arise again, we shall continue to institute drainage following cholecystectomy.

It has been our experience to have had late post-operative opening of upper abdominal wounds in a few cases in which the wound had undoubtedly been the site of a low grade infection of sufficient extent to interfere with healing. While practically all of the cases recover uninterruptedly with secondary suture, we feel that the possibility of the occurrence of this condition may be diminished by the intro-

duction of a considerable number of through and through rubber-covered stay stitches, together with late removal of the stitches and wide supporting straps.

The foregoing conclusions were reached from an investigation of one hundred and twenty-six gallstone cases. This group of cases was selected from our private records rather than from our public hospital service because we anticipated more complete, adequate and numerous answers to our questionnaire.

Of the records of 126 gall-bladder cases studied:

64 of 85 cases submitted to cholecystectomy were traced.

Of this number 51, or 80%, reported themselves as cured.

6, or 9.3%, reported themselves improved.

3, or 4.5%, reported themselves as no better.

4, or 6.2%, died.

28 of 41 cases submitted to cholecystostomy were traced.

16, or 61%, reported themselves cured.

7, or 27%, reported themselves improved, but with symptoms.

2, or 7.7%, were operated again.

3, or 11.5%, died.

11 of 15 cases submitted to choledochostomy for common or hepatic duct stone were traced.

8, or 72%, were cured.

2, or 18%, were improved, but with symptoms.

1, or 9.9%, died.

CONCLUSIONS.

A careful history is usually the most dependable feature in the diagnosis of gallstones.

There are no harmless gallstones and they should be removed as soon as diagnosed.

Cholecystectomy is in a great majority of cases the operation of choice, but is not universally applicable.

Obstructive jaundice usually demands delay and the use of measures to lower coagulation time.

Every dilated common duct and every common duct suspected of harboring a stone should be thoroughly explored.

Every case of cholangitis should have the common duct drained.

All successful bile passage surgery is dependent upon a long incision and adequate exposure.

DR. W. W. KEEN'S ADDRESS ON THE OCCASION OF THE BESTOWAL OF THE BIGELOW MEDAL.

THE TUBERCULAR INFECTION IN CHILDHOOD.

Study I.

COMPARATIVE ACTIVITY OF TUBERCULIN PREPARATIONS.

BY A. R. CUNNINGHAM, M.D., AND A. R. RACCLIFFE, BOSTON.

Work done at the Boston Dispensary children's clinic of Dr. Maynard Ladd under a grant from the Massachusetts Tuberculosis Association and initiated by Dr. Edw. O. Otis, President of the Association.

By combined methods, over 1200 children have been tested in the Boston Dispensary with tuberculins, both human and bovine, since July, 1921. Discrepancies soon appearing between the results obtained and those reported by other authors made it seem important to investigate the activity of tuberculin as prepared by different manufacturers. The tuberculins referred to in this comparative study are in each instance human O. T. This material is available from many laboratories—commercial, state, and those of some of the larger hospitals. The Massachusetts Health Department, however, does not furnish tuberculin. The Saranac Laboratory at Trudeau, N. Y., furnishes human tuberculin gratuitously, for experimental purposes, to hospitals and clinics only. The preparations generally used in testing individuals in hospital and private practice are probably those from commercial laboratories, and it seems, from personal communications, that investigative work is often carried on with preparations from state departments of health and sometimes with the Trudeau preparation. We were unable to obtain tuberculin from the New York State Laboratory and have tested no tuberculins from state health departments.

The federal public health service does not control the preparation of tuberculin designed for purely diagnostic purposes, or supply any standard with which such preparations might be compared. There is, in fact, no existing method of standardizing tuberculin which is in any way satisfactory, although various efforts have been made to evolve one. Guinea-pigs are too variable in susceptibility to tuberculin for the use of lethal units as a standard. The activity of any preparation can be ascertained only by trial upon a number of known positive persons and seems to depend chiefly upon the use of full-grown cultures of the bacilli. In a personal communication we have received the suggestion that the inferiority of some preparations may be due to the use of cultures which are not fully ripe and which are boiled too long. Preparations of tuberculin are expected to sustain ageing up to five years without considerable

loss of potency and may be kept at room temperature for the entire period.

Reasons for suspecting the activity of some tuberculins may be found not only in our own experience but in examining a few recent reports from other investigators. Using the Pirquet method, Arnfinson¹, in 6978 public school children in Norway, obtained positive reactions in 37.8%, a figure which would be modified downward, without much doubt, were children below school age included. Sill², in 658 New York children from infancy to 13 years of age, found only 9.2% giving positive reactions. In this group there were none whose family records showed tuberculosis. Sill concludes that the incidence of the tubercular infection varies not only in different countries but in the different cities of the United States. Pirquet himself³ found 56% positive in Vienna children who were from 11 to 14 years of age. The results from different authors from the Pirquet method in children, seem to average in the vicinity of 38%, with a proportionate representation of all ages up to 14 years, but wide variations in the results obtained by different authors are, in our opinion, due largely to the use of tuberculins of inferior quality and to technique rather than to regional variations in the incidence of the infection.

In the children upon whom this study is based tuberculin was applied both by the Pirquet method and by the intra-cutaneous method of Mantoux, both methods being employed on each patient. For the intradermal tests a dilution of 1-250 or a dosage of approximately .1 mg. was chosen after much experimentation, as giving the highest percentage of positive reactions without any so severe as to cause ulceration. Successive tests with increasing doses would be more acceptable if the incidence of the infection was to be determined rather than the comparative activity of the tuberculins. A sample of tuberculin from a commercial laboratory was used until several hundred children of all ages had been tested. This preparation is the one later described as "No. 1." The average age of these children was 6.6 years and positive results were obtained in only 24%. The positive percentage in children of school age for comparison with the figures of Arnfinson was 31%, and from 11 to 14 years of age 42% were positive as compared with Pirquet's 56%. These figures, representing the combined results of dermal and intradermal tests in our group, are compared with dermal results alone in the reports of the other investigators and do not seem to satisfy.

"No. 1" was thereupon discontinued and another commercial preparation was employed in testing a second group of children. This second tuberculin is designated "No. 2." The age average of this group was 6.8 years and the percentage of positive reactions rose to 36.2% but still seemed too low. From the ages 5 to 14 the

positive percentage was 45.5% and from 11 to 14 years it was 58.1%.

A third group was tested with tuberculin "No. 3." The average age was 7.5 years and the percentage of positive reactions was 47.1%. From 5 years to 14 years inclusive this percentage was 50.9% and from 11 to 14 years, 67.8%. This sample of tuberculin was that from the Saranac Laboratory.

TABLE 1.

method	av. age	% pos.	0-13 yrs.	13-14 yrs.	14-15 yrs.
Arndtson Pirquet	6.6 yrs.	21.0%	37.8%	56.0%	42.0%
"No. 1" combined	6.6 yrs.	21.0%	31.0%	42.0%	58.1%
"No. 2"	6.8 "	36.2%	45.5%	58.1%	67.8%
"No. 3"	7.5 "	47.1%	50.9%	67.8%	

Hamburger³ and other authors believe that tuberculin reactivity is influenced by the season, the author quoted stating that in the fall, children with out-spoken tuberculosis gave positive results to the delicate sub-dermal test only with relatively large doses. In consideration of this and the fact that tuberculosis is more frequent in the spring than in the fall, he believes that susceptibility to tuberculosis is greater in the spring. Without accepting these conclusions it is of interest that our worst results—those obtained with tuberculin "No. 1"—were obtained during the period from mid-July to mid-winter, while the ensuing months until July the following year were applied first to the use of "No. 2" and then to "No. 3." Consequently it was felt that simultaneous tests would be necessary in fairness to the preparations under consideration. It was also desirable to broaden the scope of the investigation to include samples of tuberculin from other manufacturers, and three more commercial tuberculins were obtained for this purpose, making six in all.

In this part of the work the Pirquet test alone was used; it was chosen because it seemed to offer more assurance that each patient would receive an equal dose of each tuberculin than would be afforded by the intracutaneous technique. The simultaneous tests were performed upon 25 adults and 3 children whose reactions were known to be positive; they were examined at the end of 24 and 48 hours and the reactions were graded from the least, which could be described as definitely positive—grade 1—to the most severe, which was called grade 4. By thus grading the severity of the reactions a more accurate comparison of tuberculin activity could be secured than if positive and negative reactions alone were considered. The results are indicated in Table 2. It is seen that "No. 3" tuberculin—the Saranac preparation—distinctly exceeds any of the five commercial products not only in the number of actual positives but in the severity of the reactions produced. The other important fact brought out by this table is that the commercial products studied vary

greatly from each other in activity and are without exception inferior preparations.

TABLE 2

Case	24 hrs.						48 hrs.					
	Tuberculin Nos.						Tuberculin Nos.					
1	1	0	1	2	1	1	1	0	1	1	1	1

26	3	2	4	1	3	2	2	2	4	1	2	2
27	2	1	2	0	2	1	2	1	1	0	1	1
28	0	0	0	0	0	0	0	1	1	0	0	1
positive severity	16	18	22	20	18	18	16	21	25	19	21	21
score	22	24	41	26	25	22	24	30	45	21	29	24

The findings indicate that the tuberculins studied, with the exception of "No. 3," are not suitable for use in determining the presence of the tubercular infection by any method whatever and that their use in previous investigations may be a cause of the lack of uniformity which appears in the results.

Study II.

INCIDENCE ACCORDING TO TUBERCULIN TESTS AND METHODS OF APPLYING TUBERCULIN.

Not too widely recognized is the fact that in living subjects, the absence of infection with the tubercle bacillus can be conclusively demonstrated only with difficulty. By single or repeated Pirquet tests which are the basis of so many attempts to determine the incidence of the infection, it appears to be possible to detect tuberculosis in slightly over half of all cases where the infection has taken place. By the subcutaneous use of tuberculin in successive injections of increasing dosage, this possibility of detection is evidently greatly increased. Ac-

cording to Hamburger¹ the reception of a dose of 1 mg. of tuberculin by this method, without a reaction, may be taken as nearly absolute evidence that the child is free from tuberculosis. According to the same author this statement has been confirmed by Reuschel, Nothmann, Pirquet, and Rominger. But this amount cannot be safely administered without first obtaining negative responses to successive smaller doses.

This method is satisfactory in individual cases where the need for diagnosis is a matter of relative urgency, although time consuming, but, requiring as a maximum, four injections at intervals of 48 hours and daily observation for a period as long as 8 days; the determination of the incidence of the tubercular infection in ambulatory dispensary patients would be attended by the greatest difficulty, although a large number of patients might be observed through one or two of the tests. For such ambulatory and comparatively irresponsible patients there appears to be no method of making this determination which is reliable and at the same time practicable. It is desirable that a method be devised by means of which a test may be completed at most in 48 hours and with a small percentage of error.

Cutaneous applications of tuberculin, whether by Pirquet's technique, or modifications of this, or by innunction, and intracutaneous injections of tuberculin seem to depend for their result upon a cellular reaction. The febrile disturbance resulting from the subcutaneous injection of tuberculin in an infected person indicates a probable humoral reaction. If the body fluids contain substances which, by concentration or by accessibility, react more sharply or more consistently to tuberculin than do the epidermal cells, then one cannot expect, by changes of technique alone, to produce a dermal or intradermal method which will be 100% efficient. The essential difficulty of the dermal method, however, seems more probably to be that of obtaining satisfactory contact between the tuberculin and the more actively sensitive cells of the skin. If the intradermal application, on the other hand, proves to be really less effective than subcutaneous injection, as Hamburger suggests, the authors believe that irregular dosage, due to difficulty in controlling the children during the injection, and leakage of the tuberculin from the needle hole, may account for the deficiency.

Having no feasible method of determining the true incidence of the tubercular infection in our dispensary children, the value of this study and its design lies in demonstrating to what extent care of technique aided by a combination of dermal and intradermal methods and selection of tuberculin may give value to the results of tests performed at one sitting and completed in one return visit after 48 hours. The obvious reason for selecting these two methods of application, and not the subdermal method, was the fact that elevations of temperature could not

easily be ascertained in these children and would unduly vex their parents.

Although over 1200 children were tested with tuberculin in preliminary work and in this and other studies, the results which we are now reporting are those obtained from only the last 346 whose tests were done under the most favorable conditions. In all these we had the benefit of a tuberculin of high activity. Two Pirquet and two intradermal applications were made upon each child. Full strength human O. T. was used in the Pirquet scarifications which were made with the usual "borer" through the drop of tuberculin, a modification which gave distinctly better results than were obtained by applying the tuberculin after the scarifications were made. For intradermal testing it was necessary in preliminary work to determine a dilution which would give a maximum number of positive reactions, without at the same time causing ulcerations or other undesirable results. For this purpose dilutions in normal salt solution of 1:1000, 1:500, 1:250 and 1:100 were tested. Dilutions of 1:1000 were found to be practically inert. Dilutions of 1:500 produced about 3% fewer reactions than those of 1:250, and dilutions of 1:100 only about 2% more than those of 1:250. In the 71 children tested with 1:100 tuberculin intradermally, however, two reacted so severely that it was thought undesirable to continue this dilution although actual ulceration did not result. These trials were carried out with a preparation of tuberculin which was later found to be one of the weakest of the commercial tuberculins. The suppositions would therefore be that dilutions stronger than 1:250 of an active preparation would be likely to cause severe reactions and that there might be greater differences in percentages between the results of the different dilutions. The 1:250 dilution was thereafter used in a great many cases and with the most active tuberculin, never causing reactions so severe as to necrose the epithelium. The calculated dosage of each dilution in the order named was .02 mg., .04 mg., .08 mg., and .2 mg. Inaccuracy is inevitable in the dosage chiefly because some children will not stay quiet and partly because of leakage through the punctured epithelium after injection.

The human tuberculin used was that furnished by the Saranae laboratories at Trudeau, N. Y., which we have shown to be an active and satisfactory preparation. In addition, one test was made with bovine tuberculin from the commercial laboratory which supplied the previously designated "No. 2" human O. T. This bovine test was an intracutaneous injection of the same dosage as that done with human O. T. Thus four simultaneous tests were performed upon each child: two Pirquet tests with human O. T., one intradermal with O. T. 1:250 (.08 mg.), and one intradermal of bovine tuberculin similarly diluted and averaging .08 mg.

per dose. The tests were examined after an interval of 48 hours.

The 346 children gave positive reactions in 57.1% and the average age was 8.1 years. The average age is, we believe, an excellent aid to the comparison of results in children and might well be included in all such reports as this. It is calculated in this study as the total number of years represented, divided by the total number of children. Those who were below 1 year of age were reckoned as 0 years. For example, if a group contained 10 children under 1 year old, 10 who were 3 years old, 10 who were 5 years and 10 who were 7 years old, the total ages would be 150 and the average age would be $150 \div 40$ or 3.7 years. The percentage of positive reactions obtained for each year of life is seen in Table 1.

0-1 yrs. 25%	5-6 yrs. 62%	10-11 yrs. 84%
1-2 yrs. 54%	6-7 yrs. 50%	11-12 yrs. 60%
2-3 yrs. 60%	7-8 yrs. 66%	12-13 yrs. 61%
3-4 yrs. 54%	8-9 yrs. 69%	13-14 yrs. 62%
4-5 yrs. 33%	9-10 yrs. 70%	14-15 yrs. 87%

The irregularities of progression from year to year which are indicated in this table are without doubt due to the small numbers of each age represented. Comparisons may be made between these figures and those of Hamburger, who obtained positive reactions in 95% of children in Vienna between the ages of 11 and 14 years, by successive subcutaneous injections of increasing dosage. Pirquet's own figures for these ages, as quoted by Hamburger, were only 56%. From Table 1 there appears to be a disproportionately high rate of infection during the first three or four years of life, at least 50% of the children having then become infected, notwithstanding the deficiencies of the tests employed.

The results of these tests indicate that a combination of the cutaneous method of Pirquet and the intracutaneous method of Mantoux may be used to advantage in groups of patients whom it is desirable to test at one sitting. By further refinement of such a combination we believe it possible to determine the incidence of the infection to within 20% of actualities as indicated by the more cumbersome method of Hamburger. Our bovine tuberculin was a commercial product. The human O. T. prepared by the same house was one of the best of the commercial preparations but distinctly inferior to that from Trudeau. Although we did not test the comparative activities of different bovine tuberculins, it is presumable that a more active preparation than ours might be used with improvement upon our results. About 10% of the reactions included in Table 1 were due to this bovine tuberculin alone, thus representing the importance of using this substance in tests of this sort.

The Pirquet method using human O. T. alone

would have demonstrated 85% of all the cases of infection detected by this combined method and is distinctly a more effective test when properly performed than the intradermal method with the dilution and dosage used by us. We would not recommend an initial injection of a greater dose than .1 mg. of an active tuberculin. The maximum initial dosage of the Trudeau preparation and the one consistently used was only .08 mg., yet the wheals produced by this amount were occasionally severe. At least 15% should be added to the results from Pirquet's test by this additional injection of .1 mg. of human and bovine tuberculin intradermally.

Study III.

INCIDENCE OF CERVICAL, EPITROCHLEAR AND PERIBRONCHIAL ADENITIS.

In the course of observations to determine the incidence of the tubercular infection of children of the dispensary class in Boston, we were led by the reputed susceptibility of the lymphatic system at this age to attempt a short comparative study of glandular enlargements in patients giving positive and negative reactions to tuberculin. Beginning this study late in the course of our other work, only 165 patients were accumulated who were examined particularly for this purpose. These children were not selected except that all were older than two years. The examinations of the glands were made in every instance before the results of the skin tests were known.

The lymphatic structures selected for this study were the anterior cervical, epitrochlear and peribronchial glands. The condition of the anterior cervical group was noted because of their liability to scrofula and because of the doubtful frequency of tubercular lesions and tubercular pathways in and through the tonsils. Enlargement of the epitrochlears is easy of detection and is always an interesting finding, especially since a lucic significance has become attached to such enlargement. The examination of these glands was undertaken to determine the influence, if any, of the tubercular infection upon the lymphatic system as a whole. The examination of the peribronchial gland group was, of course, directly indicated by their reputed relation to early tuberculosis.

Although the number of cases so examined is smaller than is desirable, they were those whose tuberculin tests were performed under the most favorable circumstances, using the very active tuberculin furnished us by Dr. E. R. Baldwin of the Saranac Laboratory. Tests with

bovine tuberculin from a commercial laboratory were also performed and the application of both tuberculins was done by the Pirquet method and by the intracutaneous method in each patient, about .1 mg. being the dose received by injection. It happened that of the 165 children so examined, 88 gave positive reactions and the incidence of the enlargement of the three groups of glands in these children is compared with that found in the 77 patients not reacting to tuberculin.

As was expected the anterior cervical glands were palpable in more than half of all the children. The frequency of the enlargement was practically the same whether the tuberculin reactions were positive or negative—57.9% in the positive cases and 58.4% in those not reacting. Except for one consideration this result is rather strong evidence against the frequently expressed view that the tonsils serve as a portal of entry for the bacillus of tuberculosis. The one factor which weakens this conclusion is the fact that all of our cases were taken from the medical clinic and were thus deficient in as many cases of scrofula of the neck as would appear in 165 children taken equally from the medical and surgical clinics. We do not believe that this deficiency seriously alters the significance of our result and we are to report later some strongly corroborative evidence from the histologic examination of a large number of tonsils.

Our examination of the incidence of epitrochlear glandular enlargement disclosed the interesting fact that 30.9% of children of our dispensary class in Boston show this enlargement. It would be gratifying to learn just what influences act to stimulate the enlargement of these glands, but it is hardly conceivable that the cause was luetic in more than a small number of these and we conclude that palpable epitrochlears is a common finding and more often due to other causes than syphilis.

Of the 88 children who reacted to tuberculin 31.8% had palpable epitrochlears, and of the 77 who failed to react, 30% showed enlargement of these glands. This comparison suggests that the primary tubercular infection in children is not a frequent cause of general glandular enlargement.

It has often been pointed out that tuberculosis is an important cause of peribronchial glandular enlargement. In examining patients for this condition we depended entirely upon the presence or absence of D'Espine's sign and the examination was made in each instance by the same person, thus excluding variations in interpretation which would otherwise be likely to occur. The children giving positive tuberculin reactions showed a positive D'Espine in 48.8% of the 88 cases, while those who did not react showed enlargement of these glands in only 33.7% and it must be remembered that this contrast would probably be more marked if more

intensive tests with tuberculin were carried out. Our findings, therefore, are corroboratory of the tubercular significance of a positive D'Espine's sign.

A PAINLESS, LITTLE LUMP ONLY AS BIG AS THE TIP OF HER LITTLE FINGER AND YET, IF NEGLECTED, IT WOULD SURELY HAVE KILLED HER, AFTER MONTHS OF TERRIBLE SUFFERING.

BY W. W. KEEN, M.D., PHILADELPHIA,

Emeritus Professor of Surgery, Jefferson Medical College.

This is the brief and happy story of a wise woman who sought and immediately followed advice in a case of malignant cancer of the breast.

A personal friend, a woman of fifty, rather stout, with a considerable layer of fat under the skin which obscured the evidence of any lump, while bathing discovered a lump, only as large as the end of her little finger, on the outside of the left breast, near the armpit. Three days later she consulted me.

On examination, at first, as it was so small and embedded in fatty tissue, I found difficulty in discovering it. As I had retired from practice a few years before, I referred her to one of my surgical friends in her own city. He operated upon her as soon as arrangements could be made. He first made an incision over this little and apparently trifling lump, cut it out and had an immediate microscopic examination made. Within a few minutes the microscopist reported that it was a malignant form of cancer, which required an immediate, complete operation. At once he prolonged his incision and completed the operation, removing the breast and cleaning out the tissues from the armpit, including all the glands, and also removing any of the muscular tissues that could possibly be involved. The patient made an uninterrupted recovery, in a few days.

This case illustrates the good sense of this woman. She had not had a single twinge of pain in this lump, but the moment she found it, she sought surgical advice and followed it.

In my opinion her future is secure. The lump was so small and had evidently been there so short a time, that there was no discoverable enlargement of the glands in her armpit. I think she has just as good a prospect of completing her expectation of life as any other healthy woman of her own age.

If only every woman would act as promptly, regardless of the absence of pain, how many a tragedy would be avoided!

New England Hospital Association.

ANNUAL MEETING MAY 17 AND 18, 1922,
AT BOSTON MEDICAL LIBRARY.

(Continued from page 667)

THE NURSES' HOME.

BY MISS GRACE HASKELL, SUPERINTENDENT OF
WENTWORTH HOSPITAL, DOVER, N. H.

WHEN Dr. Howland wrote asking me for a ten minute paper on any one of six or eight subjects, I glanced over the list hastily and thought I might be able to say something about a Home for Nurses in reference to the small hospital.

Our New England States are full of small hospitals from fifteen to one hundred beds capacity. It is very safe to say that in those hospitals under thirty beds and many over that number there has been no real provision for the housing of the nurses connected with the institutions. Upon investigation it would be found that the pupils, if any, the graduate nurses and the executive force are to be found in the same building with the patients, usually on the upper floor or in rooms adjoining patients' rooms. When this arrangement exists,—and it exists often enough to be the rule, and not the exception,—there is absolutely no freedom of speech or conduct possible for the personnel of the hospital. The wonder is with this arrangement that small hospitals ever have pupil nurses, and the question arises, ought they to have them under these conditions? The dining-room is never adequate. The meals are hurried; nurses do not get away from the hospital atmosphere during the twenty-four hours, and the accident cases, the emergency cases and the obstetrical cases are always in her immediate background. Inevitably she must leave the hospital for the change and recreation which she should be able to get by going off duty. She cannot entertain her friends because there is no place provided, and if a young man friend, she probably spends her evening going to the movies and walking back afterward to the place which should be home, and which only offers an opportunity for her to eat, work and sleep. I am speaking now of the small hospital as I have repeatedly seen it. Fortunately, the past ten years have seen a great awakening in hospital boards and executives in regard to the housing of the nurse and the manner in which she spends her time when off duty. It has been demonstrated beyond dispute that the hospital, small or large, that gives its nurses proper living conditions has more pupil nurses in proportion than those who do not. The young woman of today is wise in her generation, flapper though she be. She selects her training school with a very careful idea of its advantages and a keen observation of the home she is to live in for three years or less. Just

what should we give our nurses for a home? At least, it should be as good as that she came from. Most of the young women in training schools come from the great middle class that is the backbone of the nation. The parents wish their children to have the things which they themselves, perhaps, had to do without. They strain every energy to put their girls through High School, and having done this they feel she is on the right road toward self-support. A girl leaves this home where she has had love, freedom of expression and a perfect equality, and, if she enters a training school, she comes to—what? We feel compelled to answer, very little love, no freedom of expression, for at least eight hours of the day, and a discipline such as she in her young life never imagined. What are we going to do for her to compensate her for the loss of her family life? This brings us directly to the housing conditions.

First, let us have a building for our nurses entirely separate. If connecting corridors are necessary, let them be long enough and the entrance to them as far from the living quarters as they can be. Give each girl her own room that there may be one place where she can "loaf and invite her soul." Have toilet and bath room facilities on every floor, adequate for the needs of the number to be served. Small tables in the dining-room where different classes can join each other three times a day and exchange a little conversation that is not shop. This room should be bright, cheerful, with a fire-place if possible, and should always be in the home. Have one large living room,—large enough for general entertainment; two or three smaller sitting rooms, making it possible for the young woman to receive her friends alone if she prefers. Give them a laundry where they are at perfect liberty to go for any amount of washing or pressing. We all know it is not possible for a hospital to take proper care of the lingerie and transparent waists that are so generally in vogue. Have the class and demonstration rooms in the home. Nurses off duty will appreciate this, and nurses on duty will enjoy the change from the hospital. Give the nurses the privilege of serving simple refreshments to their friends at least once a week. Inaugurate a tea hour from four to five daily. Musical instruments, of course, should be provided. If there are porches, have chairs enough to seat half the school at least. A tennis court and croquet ground would afford good fun and much-needed out-of-door exercise. If I had sufficient funds I am sure I would install a bowling alley.

The home should not be luxurious but comfortable: the necessities balancing; the atmosphere one of freedom without license; the rulings controlling the home as few as are compatible with the protection of the building and its occupants. A gentle woman to act as house-mother and have supervision of the necessary housework. Each home for nurses, large or

small, has its own problems. Probably student government is a good thing for the student. If it could only include the proper care of the equipment I should encourage it, but it does not because there is a lack of mature judgment as to what is good care, and very little thought as to the cost of maintenance.

If the home is owned by a city there is usually a strict accounting from time to time as to the why of this expense, and the necessity of that, and the superintendent of the hospital has that accounting to do often to a group of politicians who do not really care to be shown the facts, but only wish to talk. Our hospital is just completing a nurses' home. This hospital opened in 1906 and had built for the accommodation of the nurses a wing consisting of eleven sleeping rooms, two baths, one class and one living room. These accommodations were out-grown in two years. The hospital increased its work rapidly and at the end of ten years had grown from a thirty bed to a fifty bed hospital and by the middle of June will be an eighty-five bed hospital. For fourteen years the nurses have been moved from pillar to post, and if there is any superintendent in this audience better qualified as a furniture mover than myself, I should be very glad to meet him or her at the end of the session.

Our troubles in regard to room were ended when Mr. E. W. Rollins, a generous townsman, gave us a nurses' home as a memorial for his son's wife, Mrs. Gladys Rollins. This building is erected at the cost of \$81,000, not including equipment. We have four floors, the two upper ones devoted to sleeping, bath and small sitting rooms; the ground floor to living room, sitting rooms, dining room, serving pantry, with three or four smaller rooms for each its special use. The basement has a class and demonstration room, laboratory, dietetic kitchen, laundry, trunk and boiler room. These are for the nurses' use exclusively. The donor, the architect, the trustees, and the superintendent, have been in perfect accord since the plans were first presented and accepted. The aim of all has been to keep the building a home in as true a sense as possible. The sleeping rooms are finished in white and yellow; the bathrooms in gray marbleoid. Toilet and bath facilities are adequate to the number to be served. The dining room is in buff and white with mahogany doors, a very beautiful room with a large fireplace. The living room, a replica of that of the donor, has a very large fireplace and is beautifully lighted by four large windows and French doors. The small sitting rooms are finished in ivory and white. On either end of the home French doors lead to broad porches. The fireplaces in the living, class and dining rooms are a source of great pleasure to the nurses already. The corridors are in buff and white with mahogany. There is not one dark corner in the entire home from attic to basement. The first impression one receives on entering the home is the cheer-

fulness, which is a natural result of the color scheme.

I need not further discourse about our particular home, but I will say many of the ideas that I myself have had, have been incorporated in it and it would be impossible for any superintendent to have had a more interpretive and sympathetic architect to deal with or a more liberal, progressive Board of Trustees. The donor, a man of very large experience in business life, has co-operated, as I have before stated, with all three.

Our plan is to keep our nurses happy and we have tried to have that happiness come from within the home.

DR. HOWLAND: I am sure there is plenty to talk about on a paper of this kind. The Nurses' Home is open for discussion.

MISS HALL, Peter Bent Brigham Hospital: I should like to endorse nearly everything Miss Haskell has said, particularly the single bedrooms. To make the nurses' living quarters attractive, nothing is so much needed as small rooms in which to entertain their guests. Not enough attention is given to that in planning nurses' homes. Another thing I should like to emphasize is the proper equipment of class rooms; I think we ought to have more complete teaching rooms than we have. I want to put in a plea for adequate class rooms; not only a room for lectures, but a generous room for demonstration, with proper equipment, and a utility room connected with it, corresponding to the utility rooms in the wards, so that all articles used in teaching and in demonstration can be placed in that utility room. I think this has been worked out in some institutions; I think Miss Doherty has worked it out at Holyoke.

MISS DOHERTY: We have just had a new nurses' home, of which we had long been in need. For several years, the nurses lived in a part of the hospital. Our hospital has 125 beds, and we have had the disadvantage of having no nurses' home for many years. It was only this year that we succeeded in getting a nurses' home, and already the applications for entering the training school have increased. I should like to offer that as the solution of the problem of the shortage of nurses. We think that it is going to be a great drawing card in securing applicants. Our home is a fire-proof structure, of three stories, and accommodates fifty students in single rooms. The living room has a beautiful fireplace. It also has French doors and a very appropriate lighting system. Down stairs we have class rooms and a recreation room. We also have what Miss Hall spoke of, a utility room, planned as nearly as possible like the utility room in the wards. We have sun porches, a tea room, and kitchen. We also plan on teaching chemistry and domestic science in the nurses'

home, so we have a chemical apparatus and facilities for teaching practical cooking. Our aim has been to have certain people give certain rooms as memorials. The home was built by the citizens of Holyoke. Several prominent citizens have been interested in certain rooms, and therefore we have been able to have a little more elaborate equipment than we could have had if the hospital itself had had to provide it. The nurses appear to be delighted with it. Already they have plans to have their friends come and see them. Probably the best thing yet done for the hospital and for the training school has been to open the nurses' home. We invite anybody to inspect the building.

DR. HOWLAND: What are your standard furnishings? or are they uniform?

MISS DOHERTY: They are not uniform. We haven't yet got it completely furnished. We took our furnishings which were in the students' rooms and had that renovated, and added to it when necessary. Each room has a white bed; we have no couches; the general feeling was that the student would prefer a single bed. Each room has a rocking chair and a straight chair. Some of the rooms have been provided with a table and a book rack. Each room has a dresser, and each has also a student's desk lamp. There is also general illumination from the ceiling. We have throughout the nurses' home the vapor system of heating. Our old quarters were very noisy, with the old form of steam radiators. The vapor system is noiseless, and the heat can be turned on from one-fourth to three-fourths.

Q. What is the floor covering?

The floor is reinforced concrete, with linoleum covering. There are bathrooms at each end of the building, with fixtures of the most improved kind. There are groups of three rooms for the staff; they have their own bathrooms. We have no sitting rooms for the staff, which was felt to be a disadvantage; but we are to have a large living room, a small reception room, and down-stairs, a recreation room. They have a reference library.

DR. HERSEY: Mr. Lee has a new addition to his nurses' home—a bowling alley and most artistically fitted-up rooms.

MR. LEE, Waterbury Hospital, Conn. We are one of the few Connecticut hospitals that have had no real difficulty in getting pupil nurses, and I attribute it almost entirely to the fact that we have what we call a good nurses' home. Considerably over 50 per cent. of our applicants are recommended by former graduates. The home has ninety-three rooms in all; contains class rooms, demonstration rooms, a utility room, a reference room. We have two bowling alleys, which are used very freely, and

are growing constantly in popularity. We have a laundry for the use of the nurses; two reception rooms, one large and one small, where they may entertain their friends. We have a small infirmary and two bedrooms with connected bathrooms, and sitting room adjoining where a girl who is sick, but not sick enough to go into the hospital, may spend a few days. We have found that very advantageous. Every room is fitted with hot and cold water; a mahogany, four-post bed, a dresser, a small writing-table, with a table lamp, as well as other illumination. We have a pretty good tennis court, and we expect to have more than one. We also have an assembly hall on the top floor, used for social gatherings, dancing and otherwise. The floors are covered with linoleum, with rugs on the bedroom floors. There are ample bath facilities on every floor. At the time we put in the bowling alleys, we first planned on swimming pools, but when we looked into it we found the cost of upkeep was rather prohibitive. We were also influenced a little by the fact that the public schools have a swimming school, which is open to the public, and we have one night a week when the nurses attend the swimming school. They take advantage of that; there were twenty-two in the last class.

MISS RIDDLE: There is much to be said in the way of appreciation of Miss Haskell's paper. I want to emphasize the point she made regarding the person in charge of the home. The person in charge of the home should be a refined woman, and I believe she should also be someone who is not a nurse, in order that the students may come in contact with someone from the outside world. If she is a refined woman, with a good personality, their happiness will be by so much increased. It is good policy to have a woman of the right kind, for it certainly does have an influence on the character and the number of applicants to the training school. It is very common in these days for the parents to come with the girls when they come to the hospital to make application, and when they find that the girls are under the care of a competent and desirable woman, they encourage them to come.

MR. STEVENS: I am very glad all these points were brought out in regard to the nurses' home becoming a real school for nurses and that in many of the newer homes school facilities are being accentuated. It seems to me that we should provide the nurses' home with every facility, so that the initial teaching of the pupil nurses may be done in the home itself. It seems to me that we should have a real ward, with real beds, with enclaustrators, with sick-rooms, with the equipment found in the hospital, so that the pupil nurse would find there every bit of equipment that she would find in the hospital, and begin the experiment on the Chase doll, and not on the patient later. I think labora-

tories should be provided, and other class rooms as well, so as to make it a real school for the pupil nurse.

Another point, which has not been brought out, is the matter of providing for night nurses—whether they should be in a separate part of the home; whether nurses while on night duty should move from their own rooms to a section devoted to the night nurses, or whether their rooms should simply be placarded, "Night nurse sleeping," or something of that sort. Another question, Is it desirable to have in every nurse's room running water, instead of having wash-bowls in the general toilet? That seems to me to be rather an important thing. Just how far should we carry the infirmary in the nurses' residence? Should we make it a real section of the hospital where the nurse could be carried through a slight illness, with an attending nurse? Also whether we should provide them with facilities for doing a little cooking, or preparing poultices, or anything of that sort; whether we should make a separate little infirmary? These are the reactions which occurred to me.

DR. HOWLAND: Mr. Stevens asks: Shall night nurses going on night duty give up their rooms, and move to rooms set apart? or shall their own rooms be placarded? Is it desirable to have running water in each nurse's room? How far should we go in having an infirmary in the nurses' home?

MISS HALL: There should be separate rooms for night nurses. I think it is most desirable to have separate rooms for night nurses, where they shall go to sleep, but most undesirable to make her move her belongings to those rooms. Nurses are constantly moving, as it is. She lives in one part of the hospital as a probationer; then later she moves to another room, then she goes on affiliation and moves to another hospital; then she goes back to her own hospital. The result is she is moving all the time she is in the hospital; and to be required to move when she goes on night duty and again when she comes off, is too much. The day of moving is a hard and interrupted day. I know, because I have been through it myself. A day of moving means that the nurse doesn't get much time for sleep when she is going on duty at night. For nurses doing night duty, quiet rooms should be set aside, shut off by fire doors or silence rooms; then the nurse should be allowed to retain her own room during that period of night duty.

Q. How much is the additional cost of putting running water in the rooms?

MR. LEE: I can't tell; but I think it is well worth every dollar put into it.

DR. SEXTON: For the night nurses, we have provided a building away from the nurses' resi-

dence and away from the hospital, where all night nurses sleep. There is no activity in or near this building. They retain their rooms during the period of night nursing.

DR. HOWLAND: Miss Haskell spoke about a dining room in the nurses' home. We have somewhere to think about economy, and I should think there was some question about that. It may be very desirable, but it is a distinct additional cost, if you must have a separate kitchen and a separate dining room in the nurses' home. That is duplication. We try to get away from that, and to centralize things as far as possible. Though it might be pleasant, it doesn't seem to me as if it were necessary to have the nurses' dining room in the nurses' home. I think the results, in the long run, might be that they would get fully as good cooking if the meals were all prepared and served from a central kitchen and serving room. There is a very distinct tendency to have the nurses' rooms apart from the hospital, and I am not sure that I am right about this; but it would seem to be an additional expense and perhaps not as essential as other features we might think of.

MISS HASKELL: Ours is a small hospital, and we have planned for the transportation of food from the general kitchen by means of a Drink-water carriage. The distance the food has to go to the nurses' dining room is perhaps not greater than that which the food has to go in a large hospital from the kitchen to the nurses' dining room. How practical a dining room in the nurses' home might be in a large hospital, I am not competent to judge, because my experience has been entirely in small hospitals. The Drink-water food car is an experiment. At first we planned to have steam tables electrically connected; but after investigation, we decided that we could afford the experiment, because the cost was not very great. We have about eight containers. They advertise that hot things will keep hot, and cold things cold. If they don't stay hot, our nurses will still have hot food, because we have facilities, in a large serving pantry which is connected with the dining room, for keeping things hot.

(To be continued.)

SMALLPOX IN THE PHILIPPINES.

The Monthly Bulletin of the Philippine Health Service reports that for the month of May, 1922, no deaths from smallpox in the Provinces were reported and no cases were reported. Since January there have been 183,254 vaccinations. When smallpox in the Philippines takes its place among the vanishing diseases some of the ammunition of our anti-vaccinationists will be denied them.

THE RIGHTS OF TENANTS CONCERNING THE FURNISHING OF HEAT.

Some annoyance has been expressed from time to time by some tenants because of alleged indifference of landlords to the discomfort of inadequately heated apartments. Under some circumstances the lack of heat may be a health problem.

The Commissioner of Health of the City of Boston has furnished a reprint of the law relating to this matter as follows:

[CHAP. 357.]

AN ACT EXTENDING THE PROVISIONS OF LAW AFFORDING TEMPORARY RELIEF TO TENANTS.

Be it enacted, etc., as follows:

Section 1. Section two of chapter two hundred and fifty-seven of the General Acts of nineteen hundred and nineteen, as amended by chapter five hundred and thirty-eight of the acts of nineteen hundred and twenty and by chapter four hundred and eighty-nine of the acts of nineteen hundred and twenty-one, is hereby further amended by striking out, in the third line, the word "February" and inserting in place thereof the word "July,—so as to read as follows:—Section 2. This act shall take effect upon its passage, but shall become null and void on the first day of July in the year nineteen hundred and twenty-three.

Section 2. Section two of chapter five hundred and fifty-five of the acts of nineteen hundred and twenty, as amended by chapter four hundred and ninety-one of the acts of nineteen hundred and twenty-one, is hereby further amended by striking out, in the second line, the word "February" and inserting in place thereof the word "July,—so as to read as follows:—Section 2. This act shall become null and void on the first day of July in the year nineteen hundred and twenty-three.

Section 3. Section six of chapter five hundred and seventy-seven of the acts of nineteen hundred and twenty, as amended by chapter four hundred and ninety of the acts of nineteen hundred and twenty-one, is hereby further amended by striking out, in the second line, the word "February" and inserting in place thereof the word "July,—so as to read as follows:—Section 6. This act shall become null and void on the first day of July in the year nineteen hundred and twenty-three.

Section 4. Section three of chapter five hundred and seventy-eight of the acts of nineteen hundred and twenty, as amended by chapter four hundred and eighty-eight of the acts of nineteen hundred and twenty-one, is hereby further amended by striking out, in the second line, the word "February" and inserting in place thereof the word "July,—so as to read as follows:—Section 3. The act shall become null and void on the first day of July in the year nineteen hundred and twenty-three. (Approved May 2, 1922.)

In addition the Commissioner has forwarded the subjoined circular which gives an interpretation of the law and advice to tenants, which may be of value to physicians who find patients suffering discomfort from lack of heat in apartments.

BOSTON HEALTH DEPARTMENT.

SETTLEMENT OF DISPUTES BETWEEN LANDLORDS AND TENANTS CONCERNING THE HEATING OF RENTED PROPERTY.

In view of the very considerable number of com-

plaints received by the Boston Health Department, alleging failure of landlords to supply sufficient heat for premises and parts of premises rented by them, the attention of such complainants is called to the following statement, showing just what the Health Department can and cannot do with respect to the matter and advising complainants as to the course to be followed in order to adjust such grievances as they may have.

1. There is no law nor ordinance which empowers the Health Department to compel landlords to furnish heat to tenants. Whether a landlord is or is not obligated to furnish heat for his tenants depends entirely upon the expressed or implied agreement between the landlord and the tenant. The Health Department is willing enough to investigate complaints relative to the inadequacy of heat in rented premises or parts of premises—and in some cases may even be of assistance in remedying conditions complained of, especially when cases of sickness on the premises make the relation of such conditions to health clearly apparent—but the limited number of the Health Department's inspectors available to attend to such investigations makes it advisable that tenants adjust their grievances by negotiations with their landlords, conducted in a friendly spirit, and, if such negotiations fail, then institute legal actions themselves in the matter in court, without the intervention of the Health Department.

2. The law recently enacted to provide means of procuring prompt action with respect to the matter of heating rented premises or parts of premises reads as follows:

Any lessor of any building, or part thereof, who is required by the terms, expressed or implied, of any contract or lease to furnish water, heat, light, power, elevator service or telephone service to any occupant of the building, who wilfully or intentionally fails to furnish such water, heat, light, power, elevator service or telephone service at any time when the same is necessary to the proper or customary use of the building, or part thereof, or any lessor who wilfully and intentionally interferes with the quiet enjoyment of the leased premises by such occupant, shall be punished by a fine of not more than one hundred dollars, or by imprisonment for not more than six months. (Acts of 1920, chapter 555.)

3. In order that the law set forth above may serve its intended purpose, in those cases in which tenants have been unable to come to any agreement by direct negotiations to procure adequate heat under the terms of their respective leases or agreements, the following condition should be complied with by the complaining tenant or tenants:

A. The complaining tenant or tenants must be prepared to show that there has been a violation on the part of the landlord of the terms of some lease or agreement under which the tenant is entitled to occupy the premises or a part thereof, with respect to the furnishing of heat. When the obligation to furnish heat is not expressly agreed to in a written contract or lease, the tenant must be prepared to show that there has been a violation of some oral or implied agreement in regard to this matter. The tenant will, of course, strengthen his case if he be able to produce witnesses to corroborate any oral agreement in regard to heat, and it would seem that the fact that the landlord has retained control of the heating apparatus, if he has done so, and that it is impracticable for the individual tenant or tenants who are complaining to control and operate it, might be regarded as presumptive evidence of an implied contract on the part of the landlord to furnish such heat as is necessary for the health and the comfort of the tenants.

B. The complaining tenant or tenants must be prepared to show that there has been a wilful or intentional failure on the part of the landlord to furnish the heat required by the lease or agreement. To this end a written record should be made of actual thermometer readings of temperature, and of the location of the thermometer in the apartment and of the time when such readings were made. If possible, the correctness of this record as to thermometer readings, location of the thermometer and time of the readings should be verified by two or more persons. If more than one tenant joins in the complaint, each should keep his own independent thermometer readings. Thermometers should be provided for this purpose if not already available.

C. If with such a temperature record as is described in the preceding paragraph the complaining tenant has been unable to adjust his differences with his landlord, and if he still feels that the matter must be carried into court, then the complaining tenant should be prepared to show by written evidence or by indisputable oral testimony that the attention of the landlord has been called to the inadequacy of the heat furnished by him and that he has "wilfully or intentionally" failed to furnish sufficient heat.

D. The complaining tenant must then present himself to the clerk of the municipal court in the district in which the property with respect to which the complaint to be made is located and make to said clerk a complaint against the landlord for violation of the law quoted above. In making such a complaint it is not necessary that the tenant should produce all of the evidence he has tending to establish a violation of law on the part of the landlord, although there is no reason why he should not do so; but the tenant must present enough evidence of a lease, contract or agreement to furnish heat and of a failure to do so to make out a probable case of a violation of law. When the case comes before the court, however, the complaining tenant must be in readiness to present all of his witnesses and such other admissible evidence as he may have on which he relies to show a violation of the law.

4. It is urged by the Health Department, not only in the interest of the maintenance of harmonious relations between landlords and tenants, but also with a view to the saving of the time and patience of tenants and landlords and the saving of the time of the court, that no case be presented to the court that can by any possibility be adjusted by negotiations directly between the parties interested.

EXCERPTS FROM THE NEWS LETTER.

ISSUED BY THE NATIONAL COMMITTEE FOR THE
PREVENTION OF BLINDNESS, INC.

If any state legislation is needed which provides either directly or indirectly for the prevention of blindness and the conservation of vision, steps should be taken at the earliest moment to formulate bills and to arouse public opinion in their favor.

The National Committee for the Prevention of Blindness will be glad to be of service to any state or local organization considering state legislation. It will send the Field Secretary, in so far as his time will permit, to any state seriously contemplating such legislation, either before the meeting of the legislature or during its session.

The courses on the education of the blind held during the past two years in the Graduate School of Education of Harvard University have proved so successful that they have become a recognized part of the curriculum. This year's course opened Friday, October 6th. It is being conducted by the Graduate School of Education with the co-operation of the Massachusetts Department of Education, Division of the Blind, and the Perkins Institution for the Blind. Mr. Edward E. Allen, Director of Perkins Institution, will have charge of the course and give a majority of the lectures. With Mr. Allen will be associated Mr. Charles B. Hayes, Director of the Division of the Blind, Massachusetts Department of Education.

The course will, as heretofore, include a survey of the movement for special education for those suffering from seriously defective vision.

Dr. W. H. Hamer, Medical School Inspector of London, England, has come to the conclusion that school girls have too much work to do and that in consequence they suffer more than boys from defective vision, heart disease, anemia and spinal curvature. These can all be traced, he claims, to the same set of causes,—less opportunity for play than boys, less time spent in the defective vision, heart disease, anemia and spinal curvature. These can all be traced, he claims, to the same set of causes, less opportunity for play than boys, less time spent in the open, the performance of household duties, and a difference in school curriculum. He suggests that at least a part of the difficulty might be solved by having the boys share domestic tasks.

The latest figures of the war blind entitled to government compensation are 636. Of these, 311 are totally sightless and 325 partially blind. Training had been given to 242 of the war blind at Evergreen prior to December 31, 1921, when the Institute was turned over to the Veterans' Bureau.

The Massachusetts Medical Society.

MEMBERSHIP CHANGES FOR THE MONTH OF OCTOBER, 1922.

OFFICIAL LIST (9TH).

Compiled by the Secretary.

Fellows should consult the lists of those allowed to resign, to change their district membership and those deprived for non-payment of dues by the Council, Oct. 4, as published in the *Boston Medical and Surgical Journal* of Oct. 19, 1922.

ALPHABETICAL LIST.

Adler, Herman M., Chicago, now 119 East Huron Street.

- Adrianse, Vanderpoel, Williamstown, now Spring Street.
- Anderson, Frank William, died at Roslindale, Sept. 29, 1922, aged 37.
- Benoit, Samuel J., Gardner, office now 18 Parker Street.
- Berry, Walter D., from Battle Lake, Minn., to East Longmeadow.
- Bone, Herman D., Gardner, office now 19 Pleasant Street.
- Brennan, John P., North Adams, now 112 Main Street.
- Bunce, James W., North Adams, now 85 Main Street.
- †Bush, John Standish Foster, died at Hartford, Conn., October 20, 1922, aged 73.
- Caines, Richard J. R., Boston, now 47 Massachusetts Avenue.
- Carpenter, Robert J., North Adams, now 85 Main Street.
- Clare, Wendell P., from Chelsea to Portsmouth, N. H., 426 State Street.
- Clark, John Donovan, now Abington, Connecticut.
- Cline, Samuel, from Boston (Suffolk) to Dorchester (Norfolk), office Boston, 353 Commonwealth Ave.
- Cullen, Charles A., Springfield, from 400 North Main Street to 51 Harrison Avenue.
- Cunningham, Allan R., from Boston (Suffolk) to Winchester (Middlesex East), 45 Church Street.
- Curran, Arthur M., North Adams, now 63 Eagle Street.
- Curran, William L., North Adams, now 63 Eagle Street.
- Cutler, Elliott C., Brookline, from 61 Heath Street to 84 Reservoir Road (Chestnut Hill).
- Dennen, Ralph W., Waltham, now 301 Moody Street.
- Dolan, William Andrew, died at Fall River, October 1, 1922, aged 64.
- Donovan, Thomas R., Fitchburg, now 40 Prichard Street.
- Du Vally, Alice Butler, Boston, 201 Clarendon Street.
- Eliot, Martha May, Boston, office New Haven, Conn., 330 Cedar Street.
- Endelnske, Charles J., Boston, now care of Boston Dispensary.
- Galleani, Ila, from Boston to San Francisco, Calif., 655 Stockton Street.
- Gaugeni, Michael A., North Adams, 34 Ashland Street.
- Garbelnick, David A., Haverhill, now 96 Columbia Park.
- Gleason, Benjamin W., from Arhol (Worcester North) to Boston (Suffolk), 86 Charles Street.
- Goss, Arthur V., from Taunton (Bristol North) to Williamstown (Worcestershire), 17 Bulky Street.
- Granger, Frank B., office Boston, 520 Commonwealth Avenue, now 520 Beacon Street.
- Greene, Thomas Francis, died at Roxbury, October 24, 1922, aged 60.
- Gurjian, Leon K., from Worcester to Lynn, 631 Western Avenue.
- Hartwell, John B., Colorado Springs, Colo., 1121 North Tejon Street.
- Hastings, Robert Worthington, died at Brookline, October 13, 1922, aged 56.
- Hopkinson, George, from Akron, Ohio, to Boston, 311 Marlborough Street.
- Hurley, Daniel B., East Boston, from 42 Chelsea Street to 158 Princeton Street.
- Hutchinson, Charles W., Concord, now 69 Main Street.
- Jackson, Roy C., from Middletown, Conn., to Brattleboro, Vermont, 75 Linden Street.
- Kelley, Clarence M., Concord, N. H., now The Parker School.
- Lavelle, Gertrude H., Natick, now 19 East Central Street.
- Luce, LeRoy A., Boston, now 416 Marlborough Street.
- McGinnick, John Joseph, from San Antonio, Texas, to Honolulu, H. I., Major Medical Corps, U. S. A.
- Mella, Hugo, from Cambridge (Middlesex South) to East Milton (Norfolk), office Boston, 106 Marlborough Street.
- Merrill, Albert S., from Hudson to Brighton (Middlesex South), office Boston, Massachusetts General Hospital.
- Merrill, Ralph E., Kutien via Foochow, Fuhkien, China.
- Metcalf, Ben H., from Winthrop to Denver, Colo., 2056 Forest Street.
- 1901-1922—Millet, Wilfrid Antoine, Pittsfield, 255 North Street. Restored by Council, Oct. 4, 1922.
- Myrick, Hannah G., from Roxbury to Dorchester, 58 Sumner Street.
- 1910-1922—Naurison, James Zuslofsky, Springfield, 172 Main Street. Restored by Council, Oct. 4, 1922.
- Owen, Albert S., Framingham, now 18 Union Avenue.
- Osgood, George E., from Wells, Me., to St. Petersburg, Fla., R. F. D. 80.
- 1911-1922—Paciariani, Sumpat Kovork, Lowell, 224 Fairburn Bldg. Restored by Council, Oct. 4, 1922.
- Paine, Mortimer H., Maynard, now 31 Main Street.
- 1904-1922—Pastene, Albert Angelo, Brookline, office Boston, 14 Charlesgate West. Restored by Council, Oct. 4, 1922.
- Parker, Willard S., Boston, now 270 Commonwealth Avenue.
- Parmenter, Derric C., from East Gloucester (Essex South) to Boston (Suffolk), 68 Pinckney Street.
- Perry, Henry Joseph, from Boston (Suffolk) to Brookline (Norfolk), office Boston, 45 Bay State Road.
- Pratt, Emily A., from Staten Island to Long Island, N. Y., 4043 57th Street, Woodhaven.
- Rochette, Edward C., Worcester, from 20 Portland Street to 14 Channing Street.
- Segal, Joseph N., Boston, from 47 Chambers Street to 536 Commonwealth Avenue.
- Simpson, Charles M., from Boston to Dallas, Texas, c/o United Fidelity Life Ins. Co.
- Smith-Petersen, Marius N., Newton Centre, office Boston, now 31 Bay State Road.
- Stowell, Frank E., Worcester, from 37 Pearl Street to 44 Pearl Street.
- Tedford, Ada H., from Woburn to Fort Sanders Hospital, Knoxville, Tennessee.
- Tobey, George L. Jr., from Boston (Suffolk) to Brookline (Norfolk), office Boston, 270 Commonwealth Avenue.
- Tobey, Harold G., from Boston (Suffolk) to Jamaica Plain (Norfolk), office Boston, 270 Commonwealth Avenue.
- Tucker, George E., Salem, from 86 Federal Street to 389 Essex Street.
- Turner, William K., Capt. Medical Corps, U. S. A., Portland, Me., Fort McKinley.
- Watkins, Harvey M., from Hathorne (Essex South) to Belchertown (Hampshire), Belchertown State School.
- Watts, Harry A., from Malden (Middlesex South) to Braintree (Norfolk South), office Boston, 100 Boylston Street.
- Wesselhoft, Conrad, Boston, from 535 Beacon Street to 306 Commonwealth Avenue.
- Wood, Russell, from Roxbury (Norfolk) to Boston (Suffolk), Boston City Hospital, South Department.
- Wood, W. Franklin, from Palmer (Hampden) to Roxbury (Norfolk), 74 Fenwood Road.

Copy for the Directory of January 1, 1923, will go to the printer soon. If you want your address in that to be correct notify the Secretary of any error at once. Changes of address should be sent to the Secretary, Dr. Walter L. Burrage, 42 Eliot Street, Jamaica Plain, 30.

THE CAMPAIGN AGAINST HEART DISEASE.

Recent publication of discussions concerning the field of preventive medicine in heart disease by Dr. Robert H. Halsey, Vice President of the New York Association for the Prevention and Relief of Heart Disease, and by other interested physicians, makes it worth while to summarize the present status of this very important subject.

Some years ago, just prior to the war, the New York Cardiac Clinics became affiliated and formed the New York Association for Cardiac Clinics. Also there was established in New York City the Association for the Prevention and Relief of Heart Disease, which had a wider outlook and membership and which included on its rolls the members of the New York Association of Cardiac Clinics. There was an interruption of the work of both Associations during the war but in the last three years both organizations have resumed considerable activity and now present to the public, medical and lay, a considerable program of endeavor.

Following the example of New York, other cities—Boston, Philadelphia and Chicago in particular—have organized in varying degrees a campaign against heart disease. The Boston Association of Cardiac Clinics was informally organized in the winter and spring of 1921. On February 23 of that year the chiefs of the Cardi-

ac Clinics in the various hospitals in the city—the Children's Hospital, Boston City Hospital, Peter Bent Brigham Hospital, Boston Dispensary, and the Massachusetts General Hospital—were called together with a few others interested in the work to discuss the organization of an association. The first public meeting was held at the Boston City Hospital on May 20, 1921. At this meeting Dr. Robert H. Halsey, at that time the Chairman of the New York Association of Cardiac Clinics, gave an account of the experiences and work and plans of the New York Association.

During the past winter and spring, 1921-1922, four public meetings were held by the Boston Association of Cardiac Clinics at different hospitals. In November at the Massachusetts General Hospital papers were read on "The Diagnosis of Heart Disease, with Especial Reference to its Importance in Preventive Medicine" and on "Problems for Cardiovascular Research." In January at the Peter Bent Brigham Hospital Dr. William P. St. Lawrence of St. Luke's Hospital, New York City, spoke on "Potential Heart Disease and The Development of Organic Heart Disease in Children." On March 16, at the Boston City Hospital, papers were presented on "The Heart in Industry" and "Exercise Tests and the Vital Capacity." At the Children's Hospital on May 18 of this year there were two papers, one on "Heart Disease in the Community" and the other on "Heart Disease in the Schools."

It is planned to hold four more meetings during the coming season, the first one in November (the 16th) on the subject of "Syphilitic Heart Disease;" one in January (the 18th) on the subject of "Heart Disease in Pregnancy;" and the last two meetings in March (the 15th) and May (the 17th), at which two or three of the following subjects will be taken up: Arteriosclerosis and Heart Disease, Hypertension and Heart Disease, The Prevention and Treatment of Heart Failure, Thyroid Heart Disease, Congenital Heart Disease. There will be again a rotation of meetings in the various hospitals in the city. It is urged that all doctors and medical students, nurses and social workers, and lay people who are interested should attend these meetings.

The Boston Association of Cardiac Clinics is now planning to expand widely into an organization to be called The Boston Association for the Prevention and Relief of Heart Disease. This will be incorporated with a Board of Governors within a few months and there will then be a wide invitation extended for membership of all kinds, in order to obtain further workers in the field and in order to obtain financial support for much-needed progress. Again the support of the medical profession and of the public at large is requested for the very vital work of the study of heart disease.

It was not many years ago that many diseases

were considered, as part and parcel of human life, acts of God. Gradually various infections and other pathological conditions have been combated. Tuberculosis, typhoid fever, diphtheria and malignant diseases have all been attacked. Extensive organizations, particularly in the study and control of tuberculosis and cancer, have existed for years. Steady progress has been made in the control of these conditions, but there is still much to be done. One of the very last diseases to be attacked is that of the heart; now interest has grown up by leaps and bounds throughout the country and throughout the world in the possibility and probability of the prevention of a considerable amount of heart disease. Rheumatic fever, syphilis, hyperthyroidism and the factors leading to hypertension and early arteriosclerosis are the points of attack. Much research is necessary and much education of the public. A national committee has been appointed for the affiliation of the work on the prevention and relief of heart disease in the various cities of this country. We must see that Boston and New England hold up their end of the responsibility in this field of medicine.

SENSATIONAL STATEMENTS IN THE PUBLIC PRESS RELATING TO MEDICAL TREATMENT.

Many newspapers frequently carry references to practitioners of medicine and methods of treatment. These are matters of interest, for disease is omnipresent and people are hoping for cures for all human ills. Some papers seem to be regardless of truth and present unreasonable statements about medicines, surgical operations and work done by members of the medical profession.

At the present time great interest is being taken in the treatment of diabetes by the use of pancreatic extract. Unconfirmed assertions have been made setting forth the revolutionary effects following the use of this agent, and newspapers have published accounts of alleged interviews with physicians. In one instance a prominent physician was reported to have endorsed the "cure." The standing of two large daily papers led the *Boston Herald* to repeat the alleged assertions of this doctor, but upon learning of the categorical denial of the published statements, the *Herald* expressed regret for the error committed in an honorable and manly fashion. We congratulate the Editor for the stand taken.

This JOURNAL finds through a reliable source that the time has not arrived for the publication of definite statements relating to the use of the pancreatic extract in cases of diabetes, because the whole subject is still in the experimental stage. Competent investigators have agreed that nothing further should be published

until Dr. Banting has brought forward additional information in his possession and competent investigators have conferred together. It is proposed that when the time for publicity shall have arrived the results of the work done in many laboratories will be published simultaneously in one journal.

The profession should endorse the attitude taken by the scientific workers in this field because the premature announcement of an important therapeutic agent might bring discredit to medicine and work harm to patients. If the pancreatic extract has value, its application will probably have to be subject to carefully regulated dosage and the coincident behavior of the disease will also probably have to be under expert observation. The history of specific medicines demonstrates that even with these drugs, intelligent adaptation to the disease is necessary to get results and protect the patient.

With all gratitude to the men who are concentrating on this problem let us wait patiently for their verdict.

THE SAMUEL FULLER MEMORIAL.

The attention of physicians, and of others interested in the history of medicine and of this Commonwealth, is again directed to the Memorial Fund which a committee of the Massachusetts Medical Society is endeavoring to raise to the honor of Doctor Samuel Fuller, physician of the *Mayflower* and of the Pilgrim settlement at Plymouth.

As long ago as February 10, 1916, the late Dr. Thomas F. Harrington of Boston published a piece of correspondence in the JOURNAL, on "The Surgeon of the *Mayflower*," sketching the life and services of Dr. Samuel Fuller, and suggesting that recognition should be given to him by the medical profession at the celebration of the Pilgrim Tercentenary.

On December 16, 1920, Dr. Charles H. Bangs, of Swampscott, Massachusetts, published in the JOURNAL a more extended article on "The Pilgrim Physician." At the meeting of the Council of the Massachusetts Medical Society in June, 1921, Dr. Bangs urged that "the Massachusetts Medical Society take steps in this tercentenary year to make a suitable memorial to that eminent pioneer physician." Accordingly Dr. Bangs, and Dr. George O. Ward of Worcester, Dr. Myles Standish of Boston, and Dr. Edgar D. Hill of Plymouth, were appointed a committee, under the chairmanship of Dr. Robert M. Green of Boston, to consider some suitable memorial to Dr. Fuller.

After several meetings during the tercentenary season, this committee reported to the Council on October 5, 1921, that it had considered several propositions, but was unanimous in recommending that the memorial should take the form of a fund, to be known as the Samuel

Fuller Memorial Fund, to be applied to the establishment of a bed or ward at the Plymouth Hospital. This report was referred to the Committee on Membership and Finance, which, on February 1, 1922, again reported to the Council, approving the project but not recommending an appropriation of money from the treasury of the Society. The Council, therefore, voted to accept the recommendations of both committees and delegated further action on the Samuel Fuller Memorial to the original committee in conference with the President of the Society.

In accordance with this action the Samuel Fuller Memorial Committee appealed last spring through the JOURNAL to the medical profession for subscriptions of not more than five dollars to the Samuel Fuller Memorial Fund. A few physicians responded promptly and generously. Their contributions were acknowledged in the JOURNAL, and a suitable certificate was sent to each subscriber. Since this time, however, interest in the Samuel Fuller Memorial Fund seems to have waned; and the committee is now moved to call attention to it again, in confident expectation of a more extensive response.

The services of Dr. Fuller as the pioneer physician of New England are unique. Not only was he the sole practitioner of medicine aboard the *Mayflower*, and in the Pilgrim community during the bitter hardship and distress of its first year at Plymouth; but later, as that community was extended by other settlements along the Massachusetts shore, he extended his ministrations as practitioner and consultant, so that his name and personality were known throughout the New England colonies of the seventeenth century. These services should not now be suffered to lapse into oblivion. And it has seemed that the best memorial perpetuation of them will be in the form of such a fund as the Massachusetts Medical Society is now endeavoring to raise, to continue in the Plymouth community the service to humanity which Dr. Fuller so freely rendered during his own life.

This fund, which is peculiarly a memorial by physicians to a physician, will be held in trust by the committee and its progress regularly reported to the Council and the Society. Its nucleus is already securely invested in a savings bank; and when it has reached sufficient size, it will be presented by the Society to the Plymouth Hospital, for the endowment of a free bed or ward in memory of Doctor Samuel Fuller, the Pilgrim Physician, the income only to be used for its maintenance. The memorial will therefore be permanent, a perpetual potentiality for good, for the relief of the same human suffering and misfortune as those which Dr. Fuller gave the labor of his life to alleviate.

In another column of this issue of the JOURNAL is published a complete list of those who have already subscribed. Further contributions will be duly acknowledged in the JOURNAL,

and a suitable certificate will be sent to each subscriber.

Subscriptions should be mailed to the chairman of the committee, Dr. Robert M. Green, 496 Commonwealth Avenue, Boston.

STANDARDS OF MOTHERS' MILK IN AUSTRALIA.

The Medical Journal of Australia reports that the Commonwealth, New South Wales, Queensland and Western Australian health authorities have adopted an arbitrary standard composition of human milk at 1.5% protein, 3.5% fats and 6.5% sugar but permit a 20% variation of each constituent. The Victorian authority also accepts this arbitrary standard of composition but is not prepared to recognize any fixed variations in the percentage of sugars.

A study in 1915 of the composition of mothers' milk in Australian women showed that the fat content varied between 0.56% and 7.6%, the average being 3.14%, which is lower than the figure on which the legal standards are based. The women from whom the milk was obtained were all apparently normal and the babies were well nourished. During the first eleven days the fat content of the milk of these women rose from 2.8% to 4.1%. It was contended that nature provides a variation of 80% below the mean and 15% above.

The comment on the situation by physicians is severe for it is felt that the standards adopted are too arbitrary and not in accordance with physiological facts.

THE SPAHLINGER TREATMENT OF TUBERCULOSIS.

REPORTS from England set forth that the Red Cross Society has not advanced thirty thousand pounds as the purchase price of the Spahlinger Serum, but has appropriated funds for an investigation of the treatment under scientific observation.

Spahlinger has insufficient resources to carry on production of the Serum in suitable quantities for use in many institutions. It will be a considerable length of time before the selected institutions will be supplied with material for study.

The question has been raised as to the propriety of the action of the Red Cross in taking over the function of endowing scientific investigations. The original purpose in the organization of the Red Cross did not cover such functions, and it is quite reasonable to assume that scientific investigations could be left to other organizations with advantage to all concerned.

The obligations of the Red Cross are large enough to call for the employment of all its resources.

AUTOMOBILE FATALITIES.

THE Department of Commerce announces that 10,168 deaths resulted from automobile accidents in 1921 in the death registration area. This covers 82 per cent. of the total population. The deaths due to motorcycle accidents are not included. The figures represent a death rate from automobile accidents of 11.5 per 100,000 population. This is an increase of 1.1 over the preceding year and in comparison with former years shows a steadily increasing rate. California, with a record of 24.4 heads the list. Connecticut comes next with 15.5, then New York with 15.4 and North Carolina with 15.3 next in order. Massachusetts, Rhode Island and Illinois have about the same proportion, a little over 13 per 100,000. Mississippi is the safest state in this country to live in from the standpoint of automobile hazard to life, with the proportion of 2.6 per 100,000.

There can be no doubt of the value of the proper use of the automobile, but there is reasonable doubt of the necessity of the greater proportion of fatalities. The automobile may be a valuable addition to health in its power to provide recreation. It may be that the entertainment and open air life incident to its use actually adds to life and efficiency and offsets its bad features, but nobody knows the exact relative values at present. It is often contended that its use by physicians adds to the efficiency of medical practice and is a means of saving life. Some patient and painstaking student may be able to console us in the future. On the other hand, the increase in the great number now in use may lead to lessened employment for purposes of recreation, for we are confronted with a congestion on our roads at times that detracts from the pleasure of automobile travel.

The larger Massachusetts cities show the following figures for 1921:

Worcester, 37 deaths; 20.0 per 100,000.
Lowell, 21 deaths; 18.5 per 100,000.
Cambridge, 19 deaths; 17.2 per 100,000.
Springfield, 23 deaths; 16.9 per 100,000.
Boston, 103 deaths; 13.6 per 100,000.
Fall River, 13 deaths; 10.8 per 100,000.
New Bedford, 9 deaths; 7.2 per 100,000.

In all of these cities except New Bedford the ratio is larger than it was in 1920.

These figures present opportunity for analyses, for such questions as the proportion of high-powered cars, the physical fitness of drivers, the relation of through travel to the number of deaths and many other questions might be studied to advantage. Worcester, Lowell, Cambridge and Springfield are cities in which there is much through travel. Boston, Fall River and New Bedford could be spoken of as more largely terminal, although Boston has

a very large number of visiting automobilists. Cities through which large high-powered cars pass in greater numbers may have more elements of danger. No analysis has, however, been made and we are left without explanation other than the facts setting forth the number of deaths and the proportion to inhabitants.

One can logically raise a question as to the greater blame of Worcester as compared with New Bedford.

SOME SUGGESTIONS AND CONCLUSIONS IN REVIEW OF THE SESSIONS OF THE SURGICAL CONVENTION.

Now that the shouting and the tumult has ceased, and the Captains and the Kings of Surgery have largely departed, it is permissible to review a little the physical and mental aspects of the 10th Convocation of the American College of Surgeons, and to regard some of the many considerations which it has conveyed and impressed.

First, and perhaps most of all, the meeting itself emphasized and accentuated to a remarkable degree that text which Dr. Harvey Cushing so aptly took for his presidential address—an admirable, important and interesting essay; an essay which should be reread by all who heard it, and studied attentively by those who did not.

"No one can be a good physician who has no idea of surgical operations, and a surgeon is nothing if ignorant of medicine. In a word, one must be familiar with both departments of medicine."

Look again at the very voluminous programme of the Congress and notice the wide catholicity of both topic and teacher in surgical matter during those very busy five days; one-fifth of the entire time was given to the broad subject of hospitals, in all their manifold elements; one evening to the presentation of a signal and well merited honor to "an institution," a Man—a Teacher, an Editor and a Surgeon—and great in all these roles; two dignified and colorful ceremonials marked the opening and ending of the sessions; and throughout the other four days, the Surgeon has been assisted and his work illuminated and clarified by the Anatomist, the Physiologist, the Neurologist, the Roentgenologist, the Syphilographer, the Internist and the leaders of practically every one of the great subdepartments of medicine. This admirable and broad view of what surgery denotes and connotes is both proper and very striking.

A second consideration totally different in character, and one which concerns the practical working aspects of the meeting, is this—that some of the most deserving and most carefully prepared clinics were but sparsely attended;

simply for the purposes of illustration an afternoon session of the Boston Dispensary may be cited. For old associations, as well as for the interest which its programme excited, a Boston doctor went to this clinic and was rewarded by as well arranged, as interesting and instructive an afternoon as can well be imagined; with an exposition of methods and end-results that were quite beyond criticism. Any large hospital in this country might justly be proud of the results of fractures and operations there shown, while the methods in vogue of initial examinations, of the conduct of the sub-departments and of general efficiency and economy of the entire institution, merited the attendance of many times the number of visitors present. This was the more to be emphasized since the work and the problems of the Dispensary, as of more than one other relatively small institution, is closely in line with that of a great number of hospitals throughout the country. Members of those staffs were among our visitors; in fact, it may reasonably be assumed that a majority of the visiting surgeons would have seen at the less well attended clinic in Boston, the attack upon and the solution of problems more nearly their own, than those which they tried to observe in the overcrowded amphitheatres of the largest hospitals. This is a practical question, fully appreciated by those who outline the meetings of the College, but it is a question for which as yet an entirely satisfactory solution has not been discovered.

Finally, was the meeting a success, and did Boston Surgery show itself to be fairly well to the fore as judged by the high standards which the American College of Surgeons proclaims and demands? To this, one can only say that frequent and apparently frank comments seemed to give an affirmative answer. In spite of pessimists and punsters, Boston may consider itself fairly worthy of its medical old masters. Ancestors are both an asset and an inspiration, and also a responsibility and a challenge. It is a fact that the next five years—even the next three—will witness the passing from the active surgical staffs of some of the largest Boston Hospitals, nearly a round dozen who for the past twenty or thirty years have worked in their wards and operating rooms; and for the past decade, at least, have borne the burden of the day and the heat.

Many of these men feel themselves still young in the physical and physiological sense, and they experience, at least in a slight degree, that vague though ancient and very human feeling of wonder as to what the veiled future holds in hidden hands for the institutions which they love so well, and which they have come to look upon, not unnaturally, as their very own. "In changeless change they go, the Singing Days;" and shortly the dozen surgeons who attain to the time-honored age of threescore years, commit the care and the conduct of and the repu-

tation of their workshops and amphitheatres to the hands of the younger men, who have so recently been their pupils, and their students!

Fortunately they may be comforted! There is no need nor excuse for apprehension! All who watched the work of the younger generation of Boston surgeons during the past week—work done under the keen and scrutinizing, though friendly eyes of the visitors, the best surgeons of America—were convinced that the future of Boston's hospitals and of surgery in Boston, is secure; it rests upon young but sturdy shoulders; it will be done by youthful but well-trained hands, directed by healthy and disciplined and able brains, for it is amply evident that, good as our surgical fathers and forefathers were, our sons will be even better!

News Notes.

CHANGE OF OFFICE—Dr. T. Chittenden Hill announces the removal of his offices from 31 Bay State Road to 270 Commonwealth Avenue.

GRADUATION OF THE FIRST-TRAINED NURSE IN AMERICA—On October 23, the New England Hospital celebrated the fiftieth anniversary of the graduation of Miss Linda Richards, the first graduate trained nurse in America. Dr. Alfred Worcester delivered an oration.

AMERICAN COLLEGE OF SURGEONS—Officers of the American College of Surgeons, who were elected at the annual meeting: President, Dr. Albert J. Oelsner, Chicago; First Vice President, Dr. Lincoln Davis, Boston; Second Vice President, Dr. John George McDougall, Halifax.

WORCESTER DISTRICT MEDICAL SOCIETY—An open meeting, to which the public were invited, was held November 8th, at 8 p.m., in Horticultural Hall, 18 Front Street. The subject for discussion was, "The Prevention of Cancer." Program: The Local Cancer Situation, Dr. Ernest L. Hunt, Worcester. Progress and Results in Cancer Control, Frederick T. Hoffman, LL.D., Director American Society for the Control of Cancer.—Consulting Statistician for the Prudential Insurance Company of America. The Cancer Society's two-reel film entitled, "The Reward of Courage." Dr. Kendall Emerson, Chairman of the Worcester Committee, presided.

NOTE.—During National Cancer Week, November 11-18, there will be public Clinics, 11-12 a. m., every day, at the Worcester City, St. Vincent, Memorial and Hahnemann Hospitals.

Physicians desiring consultations are invited to bring or send their patients to one of these Clinics at the appointed hour. The results of

the examination will be promptly forwarded to the physician in charge of the case.

LYNN MEDICAL FRATERNITY.—A regular meeting of the Lynn Medical Fraternity was held at Hotel Seymour, Lynn, on October 31, 1922, at which Dr. William E. Preble, of Boston, presented a paper upon "Obesity," with a series of charts based upon an analysis of 1000 cases.

AMONG THE CANDIDATES for Fellowship in the New York Academy of Medicine the name of Thomas Edward Cavanaugh, M.D., of Springfield, Mass., appears.

HAMPSHIRE DISTRICT MEDICAL SOCIETY.—A regular meeting of the Society was held at Boyden's Restaurant, Northampton, Wednesday afternoon, Nov. 1, at 4:30 P.M. Dr. Florence Gilman, College Physician and Director of Hygiene and Physical Education at Smith College, read a paper on "Health Building and Health Training as Part of the College Curriculum." Dr. Gilman is a national authority on the training of the American college girl.

DR. CHESTER T. COBB, Northampton, attended the annual convocation of the American College of Surgeons recently held in Boston.

WEEK'S DEATH RATE IN BOSTON.—During the week ending Nov. 4, 1922, the number of deaths reported was 222, against 176 last year, with a rate of 15.16. There were 30 deaths under one year of age against 20 last year. The number of cases of principal reportable diseases were: Diphtheria, 68; Scarlet Fever, 27; Measles, 71; Whooping Cough, 69; Typhoid Fever, 1; Tuberculosis, 39. Included in the above, were the following cases on non-residents: Diphtheria, 4; Scarlet Fever, 4; Whooping Cough, 1; Tuberculosis, 3. Total deaths from these diseases were: Diphtheria 4; Whooping Cough, 4; Tuberculosis, 14. Included in the above were the following cases of non-residents: Diphtheria, 2; Tuberculosis, 2.

CHANGE OF OFFICE.—Dr. George Gilbert Smith announces the removal of his office to 7 Marlborough Street, Boston, Massachusetts. Telephone Back Bay 10507.

HARVARD MEDICAL SOCIETY.—A meeting of this Society was held in the Peter Bent Brigham Hospital Amphitheatre Tuesday evening November 7th.

PROGRAM.

Demonstration of Cases.

Worsing to Riolan on the Pancreatic Duct.
Dr. John Donley, Providence.

The Inadequacy of the Measured Diet as an

Index of the Food Metabolized. Dr. Henry B. Richardson, New York.

THE FIRST CLINICAL MEETING of the General Staff of the Sturdy Memorial Hospital of Attleboro, was held at the hospital on Thursday, November 2nd, at 4 p.m. Program: SURGICAL, Reports of Two Cases of Uterine Fibroids Simulating Pregnancy. Dr. F. J. Carley of North Attleboro. Discussion opened by Drs. John A. Reese and Wm. O. Hewitt. MEDICAL, Report of a Case of Hodgkin's Disease and Report of a Case of Leukemia. Dr. H. L. Rich of Attleboro. Discussion opened by Drs. F. V. Murphy and A. B. Shoemaker. A buffet lunch was served at the close of the meeting.

DR. WM. O. HEWITT,
DR. JOHN A. REESE,
DR. WILFRED E. ROUNSEVILLE.

Committee in Charge.

THE RED CROSS ROLL CALL.

Membership in the Red Cross is both a privilege and a patriotic duty of American citizenship. Congress created it as the national and international agency of the United States to meet all great emergencies. The demands upon it locally, nationally, and internationally are persistent and insistent by suffering peoples at home and abroad.

The Red Cross is an army. Its members constitute this noble army fighting the battle of humanity. It is the army whose badge is service to all mankind; to humanity everywhere of whatever religion, race, color, or creed.

The emergency is here. It is now facing the Red Cross at home and abroad. Our own ex-service men and disasters at home are constantly with us. And now, the American Red Cross has responded to the appeal of the President of the United States and has definitely undertaken the work of saving the Christian and other refugees who have been driven by the Turks from Asia Minor into Greece.

The obligation met by the American Red Cross when in war time it furnished 19,877 nurses for active duty with the Army and Navy, the report just issued shows, is being met also in peace time with a reserve of nurses now aggregating 38,855, an increase of 1,068 since the 1921 report. Of this reserve 102 are serving the Army, 117 the Navy, 162 the U. S. Public Health Service, and 1,035 the U. S. Veterans' Bureau. One hundred and one nurses died during the year, three from disability incurred by service in the World War.

The Red Cross public health nurses are working in 1,145 communities in the United States, Alaska, the Philippines, Porto Rico, Hawaii and the Virgin Islands.

The Roll Call will be conducted from November 11 to November 30.

WINCHESTER'S INFANT MORTALITY.

The distinction of having the lowest infant mortality for 1921 in Massachusetts is enjoyed by Winchester. The rate is 38 per 1000, which is half the average state rate.

Maurice Dinneen, Winchester's Health Officer, has stated that this remarkable showing should be credited to the Board of Health, and is the result of many years' careful oversight of health conditions. This board has maintained a health center with a clinic under the supervision of Dr. Harold F. Simon. Instruction in pre- and post-natal work has been given by a full-time nurse. Under Carl F. Woods, Chairman of the Board of Health, the milk supply of the town has been carefully supervised.

The State Department of Health could properly give a medal to any municipality that could demonstrate such efficiency.

MASSACHUSETTS CENTRAL HEALTH COUNCIL.

A regular meeting of the Massachusetts Central Health Council was held at Hotel Victoria Nov. 1st.

The following organizations were represented:

American Red Cross by Mr. Roach.
American Society for Control of Cancer, Dr. Richardson.

Massachusetts Association Boards of Health, Mr. Kirschbaum.

Massachusetts Association of Directors of Public Health Nursing, Mrs. Stevens.

Massachusetts Department of Public Health, Drs. Kelley and Champion.

Massachusetts Dental Society, Drs. Rice and Lindstrom.

Massachusetts Medical Society, Drs. Safford and Bigelow.

Massachusetts Society for Social Hygiene, Mr. Hess.

Massachusetts Tuberculosis League, Dr. Otis and Mr. Spencer.

Dr. Champion reported progress in the maternity work of the State Department. Three physicians and seven nurses are studying conditions throughout the state. Reliable statistics of maternal mortality in childbirth are sought.

Dr. Richardson outlined the plans for Cancer Week, November 12th to 18th. District and local medical societies and hospitals will co-operate to bring about more effective control of this disease.

Mr. Walter Clark, representing the National Health Council, present by request, described the work of Health Councils in other states and outlined plans for extending the Massachusetts form of council throughout the country.

Emphasis was laid in the discussion that fol-

lowed, regarding the primary function of the Massachusetts Council, which is the meeting of representatives of the ten allied organizations for conference, discussion and reports on the work and plans of each member organization.

Publication of a popular journal through whose pages all health organizations in Massachusetts might reach a large constituency, was discussed.

Gertrude W. Peabody, Sec.,
13 Kirkland St., Cambridge.

GRADUATING EXERCISES OF THE CAMBRIDGE HOSPITAL TRAINING SCHOOL FOR NURSES.

On October 31st fifteen pupils completed the courses in the Cambridge Hospital Training School and were given diplomas.

The meeting was presided over by the President of the Board of Trustees, Dr. William D. Swan. Dr. W. P. Bowers spoke on Some of the Problems Relating to the Education of Nurses.

Miss Josephine Thurlow, superintendent of the hospital, reviewed the history of the school and reported that there are now in training seventy-eight pupils. The curriculum has been extended so as to give courses in some departments of public health nursing and the administration of anaesthetics. A large audience convened to extend congratulations to the graduates.

Obituary.

KARL VON RUCK, M.D.

Dr. Karl von Ruck, internationally known authority and specialist on treatment and prevention of tuberculosis, died in Asheville, N. C., Nov. 5, 1922, after an illness of several weeks, at the age of 73.

Born in Stuttgart, Germany, in 1849, he received his degree of doctor of medicine at the University of Tübingen in 1878. He went to England and later came to America and earned a degree of M.D. at the University of Michigan in 1879. He later studied at the University of Berlin in 1882. After some years of practice in Ohio, he settled in Asheville, where he founded the Winyah Sanatorium in 1888. This was among the first private institutions for tuberculosis treatment. In 1895 he founded the Von Ruck Research Laboratory for Tuberculosis at Asheville. He was a member of the American Medical Association, and numerous medical congresses and societies in America and in Europe, and he contributed articles on tuberculosis to medical journals in this country and in Europe. In 1872 he married Delia Moore of Ottawa, who survives him.

Correspondence.

NEURO-PSYCHIATRY.

November 1, 1922.

Mr. Editor:

This Bureau is charged with the responsibility of furnishing medical care and treatment to veterans of the World War. We find ourselves handicapped by a very serious shortage of physicians and nurses trained in Neuro-Psychiatric work. The need has become so urgent that the Director has decided to make an endeavor to give special instruction to selected doctors and nurses for the purpose of supplying our needs in hospitals and dispensaries.

I am enclosing an announcement on the subject which is self-explanatory.

Dr. Frank F. Hutchins, Professor of Mental and Nervous Diseases, University of Indiana, and the Director of Clinical Neuro-Psychiatry, U. S. Veterans' Bureau, is in direct charge of these courses and any reply that you care to send should be forwarded to this office for his attention.

It has occurred to me that you might assist the Bureau to bring this matter to the notice of your readers, by publishing such extracts or portions of the announcement as you may deem necessary and convenient.

Very sincerely yours,

ROBERT V. PATTERSON, A.J.M.,

Assistant Director.

October 31, 1922.

The United States Veterans' Bureau offers a special course in Neuro-Psychiatry to a certain number of qualified physicians on condition that upon completion of such course they will continue in the service of the Bureau for a period of at least two years thereafter.

The policy of this Bureau is to provide expert medical attention for the disabled veterans so that everything possible may be done to restore them to health and proper status in civilian life. To maintain this policy in the opening up of new hospitals, and being unable to secure the required number of specialists in nervous and mental diseases, it becomes necessary to instruct a staff of our own for this line of work. To this end a systematic and comprehensive course in Neuro-Psychiatry has been carefully outlined consisting of 176 lectures and demonstrations and some 440 hours of clinical and laboratory work. Each course will be for a period of about four months. There will probably not be more than two courses annually. Courses will be offered as long as it appears necessary in order to meet Bureau requirements. Instruction will include the necessary reviews of the fundamentals, followed by clinics and lectures on the various forms of nervous and mental diseases, including endocrinology. Special attention will be devoted to diagnostic methods, the general care of patients, and methods of treatment. Students will have actual experience in practical work. General problems of hospital administration, medico-legal questions, rehabilitation methods, psycho-metric examinations and other related matters will be adequately dealt with.

The main part of this course will be given at St. Elizabeth's Hospital, a government institution for the insane at Washington, D. C., which offers unusual and unexcelled facilities for such work. There are nearly 1,000 patients and case histories of more than 20,000 discharged patients immediately available for study. There are all classes of nervous and psychotic diseases, while other public hospitals in Washington will provide abundant clinics in so-called functional diseases, borderline cases, and the milder types.

The teaching staff that has been selected to give this course in Neuro-Psychiatry is significant. Besides the members of the staff at St. Elizabeth's there

will be lecturers from the Medical Departments of the Army, the Navy, the Public Health Service, the United States Veterans' Bureau and the U. S. Department of Agriculture. A number of America's most eminent neurologists and psychiatrists will come to deliver lectures on special topics.

As the number of students that can be accommodated is limited, early application for each course is desirable.

Further information may be secured by applying to the Bureau.

Other things being equal, members for the course will be selected in the order of their application.

Students who are authorized to take the course who are not already in the employ of the Veterans' Bureau will receive a salary of \$166.00 per month, with no allowances, while taking the course.

On satisfactory completion of the course members will be recommended for the grade of Passed Assistant Surgeon in the Reserve Corps of the U. S. Public Health Service, or they will become eligible for employment as Class "B" physicians under the U. S. Civil Service Commission and assignment to duty with the U. S. Veterans' Bureau. These salaries range from \$3,000 per year upward.

The course will start on January 4, 1923.

Approved: T. H. SCOTT, Acting Director.

THE USE OF INSULIN.

Boston, Nov. 3, 1922.

Mr. Editor:

I have been asked by many physicians and innumerable patients, during the past few months, as to the use of insulin in cases of diabetes, and I would be very glad if you would publish this letter.

As I understand it, the only place where insulin is, or can be, of use is in those cases of diabetes (so called) that are dependent on an organic pancreatic condition causing a partial loss of function of the islands of Langerhans. This form of diabetes (so called) that are dependent on an organic pancreatic infection usually entering the body through the tonsils.*

In these cases we have a distinct destructive pathological process going on in the pancreas, and we use the symptoms of blood sugar, urine sugar, and patient's loss of weight as our indicator as to how the process is going on in the pancreas, whether it is progressing or is standing still. Now, adding to the food something which will change these symptoms without affecting the destructive process in any degree, it seems to me, is something akin to treating a patient with typhoid fever by keeping him in a bath sufficiently cool to cause him to have a normal temperature. You may have slightly increased the comfort of the patient and his friends who anxiously enquire daily as to what his temperature is, but you have obliterated your principal indicator as to how the process in the intestine and the poisoning of the system is going, and consequently have destroyed one of your best indicators for treatment. But have you done anything to alter or help in the slightest degree the process which is going on in the intestine?

Of course, where the destructive process in the pancreas has progressed so far (or is steadily progressive) that the patient cannot take care of the minimum necessary amount of carbohydrate to carry on life without causing a high blood sugar and sugar in the urine, then, under these circumstances, insulin or some similar material will give comfort to the patient by allowing his system to utilize more carbohydrate than it could otherwise, and, under these

*Diabetes (pancreatic) caused by infection of the tonsils. Stephen H. Blackett, M.D. Penn. Med. Jour., March, 1921.

circumstances, its use would be justified just as is the use of morphine in the last stages of painful cancer or in the last stages of subacute glomerular nephritis.

Of course in the cases of diabetes (so called) due to a functional disturbance in the liver (the hepatic form of diabetes), which constitute the majority of the cases of so-called diabetes, a pancreatic extract or enzyme would be of extremely limited (if, indeed, any) use.

It seems to me that the story of insulin is to be analogous to that of pepsin. A great many years ago, when pepsin was first exploited, every person who thought he had any digestive disturbance took it and almost every physician ordered it for any of his patients who had any stomach symptoms.

Now in a case presenting stomach symptoms, the physician tries to find the cause and, if possible, remedy it, instead of indiscriminately giving pepsin, which, after years of use, it was learned did nothing to cure the pathological or organic condition causing the stomach symptoms in any of the cases, and only palliated the symptoms in a few cases.

STEPHEN H. BLODGETT, M.D.

PASTEUR CELEBRATION OF THE NEW YORK ACADEMY OF MEDICINE.

November 2, 1922.

Mr. Editor:

The speakers who are expected at the Pasteur Celebration of the New York Academy of Medicine are: Prof. Russell H. Chittenden, Dr. William H. Welch, Dr. Erwin Smith, Dr. Simon Flexner, Dr. Herman Biges, and Dr. W. W. Keen.

The exhibition of books, photographs, medallions, manuscripts, etc., referring to the life work of Pasteur, is to be open to the public at the New York Academy of Medicine, 17 West 43rd Street, New York, for two weeks, commencing Dec. 27, 1922.

The public addresses are to be given at the Academy on the evening of Jan. 10, 1923.

Anyone having souvenirs or memorabilia connected with Pasteur's work is invited to loan them for the Academy exhibition, and address, for this purpose, the librarian of the Academy, Mr. J. S. Browne.

Very truly yours,

W. GILMAN THOMPSON.

142 East 62nd St., New York City.

[NOTE.—Louis Pasteur was born December 27, 1822. He died September 28, 1895.]

LO, THE POOR NURSE!

Jamaica Plain, 17 Parley Vale.

Mr. Editor:

As a graduate nurse, who for some years has adopted the rôle of professional invalid, it has fallen to me to know a good many nurses and not a few medical men, and out of my knowledge thus gained, it would be a gratification to be permitted, with the profound humility felt toward the doctor by all self-respecting nurses, to ask Dr. Morse if he is quite sure that his attitude toward the nurse is justified.

For the social worker, I hold no brief, having met but two in their professional capacity. Two were a "genteel sufficiency."

The nursing contingent is largely composed of two elements—the "Mollies and Maggies" from whom one of our leading doctors recently advised us to recruit our ranks, during the acute shortage of nurses, and the women who have had better social and educational advantages.

The former class stand in too much awe of any professional class, and though they often develop into the most skillful nurses, they are too timid to ask professional advice.

The others, some of them college graduates, or coming themselves from professional homes, are too keenly aware of the demands already made on the time of a busy doctor and hesitate to enlarge his burden by the asking of questions which they feel may seem puerile and unnecessary.

Many of us, in my own day, twenty-five years ago, eagerly absorbed every word and gesture of the clinician, as we stood at salute during "the visit" and, if we could, used a stethoscope afterwards to further enhance that knowledge which we were told we must not betray, but which might be useful if we found ourselves with a sick patient a hundred miles from a doctor. I feel pretty sure it is the same in these days, and that there are few nurses who would not eagerly grasp any information, either on the medical or nursing side, if offered by the doctor. As a rule the doctor is too apt to look upon the nurse as a person of inferior grade, who works for him rather than with him. He utterly fails to understand our appreciation of him, and that some of us who might be capable might have taken his own degree, except that we shudder at shouldering the responsibility which is his—which we do not want. This is in no sense a complaint against the doctor. No class of men are braver, more high-minded, more generous, or more genuinely helpful to the community or to the individual, but I beg for a closer unity; a better understanding if, working for a common cause, we could more truly work with each other.

In conclusion, may I respectfully remind Dr. Morse that a nurse before she becomes a nurse, is a woman and that every woman is born with the knowledge that the easiest way to win man's esteem, is to ask his advice; he may thus evaluate more clearly the poise and self-control attained by the woman who takes a nurse's training.

I am morally certain that Eve's first act on realizing Adam, was to ask him if he "thought the earth, like the moon, was made of green cheese," whereupon, Adam with no previous thought as to the texture of the earth, reversed his indignation over her impudent arrival and looking down upon "the woman whom God had sent him" said, "You dear little thing."

MARY J. BIDDLE, R. N.

JOINT MEETING OF BARNSTABLE, BRISTOL NORTH, BRISTOL SOUTH AND PLYMOUTH DISTRICT SOCIETIES.

Mr. Editor:

There was a meeting of Barnstable, Bristol North, Bristol South and Plymouth District Societies at the Lakeville State Sanatorium on Thursday, November 9th. About one hundred and twenty physicians were present. An excellent dinner was served at 1 p.m. Following the dinner there was a meeting, with Dr. Sumner Coolidge, president Bristol North Society, in the chair. Dr. John W. Bartol, president of the Massachusetts Medical Society, was the first speaker. He spoke briefly on some of the aims of the state society and asked for an opinion of those present on the action of having the next council meeting of the state society at Pittsfield. The sentiment was in favor of this, Plymouth District dissenting. The next speaker was George Chandler Whipple, Professor of Sanitary Engineering, Harvard University, on Mosquito Control in Massachusetts through the better dissemination of knowledge among the people, organized study of the habits of the insect, and the organization of the communities for its eradication.

Dr. Eugene R. Kelley, Commissioner of Public Health, next expressed his regrets that Dr. Richard P. Strong was, at the last minute, unable to be present, and asked the support of everybody for the Gorham Memorial Institute. He then touched on the necessity of the recognition by the general practitioner of early tuberculosis in children, the education of the public on the curability of early cancer and

the better understanding between the general practitioner and the Public Health Department.

Dr. Benjamin White, Director Division of Biological Laboratories, demonstrated the Schick test for diphtheria. This concluded the programme.

This meeting was better attended than that of the previous year, and it was clearly demonstrated that the joint meetings are successful and should have a definite place in the Society.

Yours truly,

JOSEPH L. MURPHY.

Miscellany.

BRIDGEPORT'S HEALTH.

Under this title this Connecticut city resumes a monthly health report.

The work is organized under the following nine divisions and directors:

Administration, Miss Bessie O'Hara; Child Hygiene, C. C. Taylor, M.D.; Communicable Diseases, R. D. Fear, M.D.; Laboratories, Harriet Bixby, B.S.; Vital Statistics, Miss Cora Freyler; Sanitation, C. Howard Dunbar; Food and Milk Inspection, Harry Bartram; Waste Disposal, Health Officer; Assistant Health Officer, E. A. McLellan, M.D.

Dr. William Hall Coon is the Health Officer. He also acts as Registrar of Vital Statistics, acting under the Hon. Fred Alwater, Mayor (Ex-officio member), William L. Zipp, President, J. H. Callahan, D.D.S., Frank W. Stivers, M.D., and Antonio S. Renzi, Commissioners.

Six health stations have been organized and there are nine culture stations designed as sub-stations for laboratories. A hospital of 100 beds has been built for the care of patients, ill with communicable diseases; there is also a tuberculosis hospital. In addition to the nurses engaged in communicable disease work there are twenty nurses, to each of whom has been given a district of the city in which to work.

The report indicates that the Health Department is active and well organized.

NEW AND NON-OFFICIAL REMEDIES.

Lederle Antitoxin Laboratories: Diphtheria Toxin-Antitoxin (0.1L+).

H. A. Metz Laboratories, Inc.: Alumol.

H. K. Mulford Company: Hay Fever Timothy Pollen Extract—Mulford.

Parke, Davis and Company: Normal Horse Serum—P. D. & Co. Rabies Vaccine (Cunning)—P. D. & Co.

E. R. Squibb and Sons: Aene Vaccine. Colon Vaccine—Squibb. Gonococcus Vaccine. Meningococcus Vaccine. Normal Horse Serum. Pertussis Vaccine, Curative. Pertussis Vaccine, Immunizing. Purified Diphtheria Antitoxin (Antidiphtheritic Globulin). Pneumococcus Vaccine. Staphylococcus Vaccine. Staphylococcus Aene Vaccine. Streptococcus Vaccine. Tetanus

Antitoxin, Purified. Typhoid Vaccine. Typhoid Vaccine Combined, Immunizing.

RED CROSS NURSES FOR MAINE AND ALASKA.

The will of the late Jane A. Delano, who died in France while serving as director of the American Red Cross Nursing Service, provided for missionary nursing service.

Under this provision Mrs. Bertha R. Steeves has been selected for the Alaskan field and Miss Stella Fuller will assume similar work in the islands off the Maine coast.

These nurses will be under the supervision of the American Red Cross. *The American Journal of Public Health* has published the conditions of the bequest under which this service is to be maintained as follows:

Miss Delano's purpose in endowing this special service as a memorial to her father and mother was to create nursing facilities in isolated districts where no funds are available from governmental or other agencies or from individuals.

THE DANGER OF ASSOCIATION OF CHILDREN AND TUBERCULOUS SERVANTS.

THE New York Tuberculosis Association has made a forceful plea for care in the employment of those servants that are in close association with children.

The assertion is made that most domestic servants belong to the class which is particularly susceptible to tuberculosis because they are in the age when tuberculosis is most frequent and their indoor life and faulty habits predispose to the disease.

Again, these servants live in close contact with members of the family, handle the food and perform many kinds of personal service, especially to children. Affectionate children easily fall into the habit of kissing.

According to the last Federal census 156,667 persons were engaged in domestic service in New York City. At least one per cent., or 1560, were afflicted with tuberculosis. Several striking instances are given in the bulletin of the New York Tuberculosis Association as follows:

A young, robust Irish girl of 19 years, weighing 180 pounds, was employed as a waitress in a family with two children. She had a slight but persistent cough and tubercle bacilli were found in her sputum. One child developed a tuberculous hip and the other died of tuberculous meningitis.

The mother of one of my patients asked me to examine her houseworker for a cold which she had had for a "few weeks." The girl had extensive lesions in both lungs, a temperature of

102, and died in Bellevue Hospital of tuberculous not two weeks later. The only child in the family ran an irregular fever for some weeks during several periods in the next two years. This was undoubtedly due to activity of a tuberculous infection.

A wet nurse was referred to me for examination before going to a new baby. She had been nursing a doctor's child who had just died and had been sent to the doctor by an eminent obstetrician. She had a massive infiltration of the entire right upper lobe with a small cavity. Her lungs had never been examined.

A nurse girl of a child ten months old who was running a prolonged irregular fever and who had a positive Pirquet, was found to have an active lesion at one apex. The child died a few months later. This nurse went to her own physician, who disagreed with the diagnosis and later was seen on the street taking care of another child. She refused to change her occupation, because she preferred the opinion of her own doctor.

Three infants who were in one nursery in a maternity hospital at the same time developed tuberculosis of the middle ear and mastoid at about six months. They had all been cared for by one nurse. By the time the infection was discovered she had left training and had gone West and so could not be examined. It was impossible to avoid suspecting her of being the source.

Three children in one family were found to be infected with tuberculosis. The source was not discoverable. In that household, however, three servants have since been found with pulmonary lesions on examination at the time of employment.

The remedy consists in requiring a certificate of health of all persons who care for children, and, indeed, for all domestic servants, for tuberculosis is not the only dangerous transmissible disease.

We guard against defective plumbing, drug addiction and other disease by a system of licensing. The requirement of a health certificate would add another step in the program to bring about diminishing tuberculosis.

OPEN MEETING FOR DOCTORS

MEDICAL ADVISORY COMMITTEE, INDUSTRIAL ACCIDENT BOARD.

November 22d at 4 p. m. in the large hearing room of the Industrial Accident Board, is to be held an open meeting for suggestions and expression of opinion in regard to the workings of the industrial act as affecting the profession.

All physicians who are interested are invited to attend and participate.

Certain insurance representatives are expected to participate.

F. J. COTTON, *Chairman*,
S. H. CALDERWOOD, *Secretary*.

PROGRAM OF MEETINGS OF MIDDLESEX EAST DISTRICT, 1922-1923.

Nov. 22, 1922. The relation of the Specialist to the General Practitioner. Papers by Dr. Brewster for the Specialist and Dr. Phippen for the General Practitioner. Discussion by Drs. Whittenmore, Martin and Robbins.

Jan. 21, 1923. The Nursing Problem. Speaker to be announced later.

March 21, 1923. Mental Factors in Childhood. Paper by Dr. William Healy.

Apr. 18, 1923. Interpretation of Laboratory Findings. Papers by Dr. E. G. Crabtree and one to be announced later.

May 9, 1923. Annual Meeting.

All meetings except the annual meeting will be held at the Harvard Club in Boston.

A. E. SMALL, *Secretary*.

COMBINED MEETING OF MIDDLESEX SOUTH, NORFOLK AND NORFOLK SOUTH DISTRICT MEDICAL SOCIETIES.

In accordance with a request from the president of the Massachusetts Medical Society, a joint meeting of these three district societies will be held at Tufts College Medical School, Tuesday evening, November 21, 1922, at 8 P.M. sharp. The purpose of this meeting is to consider impending legislation relating directly or indirectly to the medical profession, to meet with the president of the Massachusetts Medical Society, and to become better acquainted with each other. Dr. John W. Bartol, president of the Massachusetts Medical Society, will talk on legislative programmes of the society.

The subject of the meeting will be "Legislative Talks of Interest to the Medical Profession," and the speakers, after Dr. Bartol, will include, Dr. James S. Stone, member of the committee on state and national legislation; Mr. Thomas C. O'Brien, district attorney of Suffolk county; and Mr. Benjamin Loring Young, speaker of the house. The meeting will be open to consider suggestions along legislative lines. This meeting will be of great interest to all, and should be supported by your attendance. A collation, no charge, will be served after the meeting.

ANIMAL EXPERIMENTATION.

WHAT ANIMAL EXPERIMENTATION HAS DONE FOR SCIENTIFIC MEDICINE.

WHAT SCIENTIFIC MEDICINE HAS DONE FOR ANIMALS.

These topics will be discussed at a public meeting of the Suffolk District of the Massachusetts Medical Society in Ford Hall, Ashburton Place, Boston, on Sunday, November 19, at 4 P.M. Dr. Charles W. Eliot, President Emeritus of Harvard University, will preside. The public are cordially invited. No tickets will be required.

SPEAKERS:

Dr. Walter B. Cannon, Professor of Physiology, Harvard Medical School. "The Value of Animal Experimentation to the Physician in His Daily Work."

Dr. Edwin H. Place, Physician-in-Chief, South Department, Boston City Hospital. "The Aspect of Antitoxins in Relation to Animal Experimentation."

Dr. Richard P. Strong, Director of the School of Tropical Medicine, Harvard University. "What Animal Experimentation Has Done for Exotic and Tropical Medicine."

Professor George H. Parker, Director of the Zoological Laboratory, Harvard University. "The Benefit to Animals of Medical Experimentation."

Dr. Lester H. Howard, Director of the Division of Animal Industry. "How Animal Experimentation

Has Assisted in the Control of Contagious Diseases Among Animals."

Dr. Arthur W. Gilbert, Commissioner of Agriculture of Massachusetts. "What Scientific Medicine Has Done for Farm Animals."

NOTICES.

The meeting of the Suffolk District scheduled for Nov. 22, 1922, is most important. See editorial in the issue of Nov. 9 for details.

THE BOSTON ASSOCIATION OF CARDIAC CLINICS announces an open meeting at the Massachusetts General Hospital, November 16, at 8.15 P. M. Subject: "Syphilis of the Heart and Aorta." Papers will be read by Dr. Walter Anderton of the Presbyterian Hospital, New York City, and Dr. William D. Reid of the Boston City Hospital. Discussion will be opened by Dr. William David Smith of the Massachusetts General Hospital.

BOSTON MEDICAL HISTORY CLUB.—Meeting at the Boston Medical Library, Friday, November 17, at 8 P. M., in commemoration of the third centenary of the birth of Molière (1622). Dr. Joseph W. Courtney will read on "Molière and The Faculty." It is suggested that remarks and contributions from other members be, so far as possible, confined to this subject.

JOHN W. CUMMIS, *Secretary*.

MASSACHUSETTS SOCIETY OF EXAMINING PHYSICIANS.—Meeting and dinner at Copley-Plaza Hotel, Monday, November 27, 6.30 P. M. Symposium on "Back Disabilities." "The Diagnosis of Back Disabilities." Dr. J. W. Sover; lantern slides. "Postural Defects." Dr. Lloyd T. Brown; lantern slides. "Backache in Women with Reference to Industrial Conditions." Dr. Stephen Rushmore. "The X-Ray Standpoint." Dr. A. W. George. Discussion opened by Dr. Francis D. Donoghue.

WM. PEARCE COUES, M.D., *Pres.*
HILBERT F. DAY, M.D., *Sec'y*.

ESSEX SOUTH DISTRICT MEDICAL SOCIETY meets Wednesday, December 13th, at Beverly Hospital, Beverly, 6 P. M. Speakers: Dr. W. P. Bowers, Managing Editor *Boston Medical and Surgical Journal*; Dr. John D. Adams, Boston; Dr. P. P. Johnson, Beverly.

R. E. STONE, *Sec'y*.

BEVERLY HOSPITAL.—A cancer clinic will be held at the Beverly Hospital, Thursday, November 16, at 4 P. M., in observation of cancer week. Doctors and nurses invited.

R. E. STONE, *Sec. of Staff*.

MEMORIAL FUND.

SOCIETY MEETINGS.

DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District:—Hyannis, —February 2, 1923, (Annual Meeting)—May 4, 1923.

Bristol:—South District:—Fall River, —May 3, 1923.
Essex North District:—Haverhill, (Semi-Annual Meeting)—Jan. 3, 1923. Y. M. O. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Suffolk District:—Combined meeting of Boston Medical Library and Suffolk District, November 22, 1922, December 27, 1922; January 31, 1923; February 28, 1923; March 28, 1923; Annual Meeting, April 25, 1923.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Hist. The date for each speaker has not been assumed.

Middlesex North District:—Meetings; Wednesday, January 31, 1923.

Worcester District meetings in Worcester, Dec. 13, 1922, Jan. 10, Feb. 14, March 14, April 11 and May 9, 1923, the last named date being the annual meeting.

The New England Ophthalmological Society meets at the Massachusetts Charitable Eye and Ear Infirmary, 233 Charles Street, Boston, Tuesday, November 21, at 8 P. M. Hospital Cases and Case Reports. Paper: "Tumors of the Optic Chiasm." Dr. Harvey Cushing, Dr. Paul Martin.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

December, 1922. New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

December 26-30, 1922. American Association for Advancement of Science meets in Boston.

January, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston, W. H. Allen, Mansfield, Mass., Secretary.

February, 1923. New England Dermatological Society Meeting, February 14, 1923, at 3.30 P. M., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

March, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary.

April, 1923. New England Dermatological Society Meeting, April 11, 1923, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

May, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), American Podiatric Society Meeting, May 31, June 1 and 2, 1923, at French Lick Springs Hotel, French Lick, Ind., H. C. Carpenter, Secretary.

June, 1923. American Medical Association, San Francisco, June 25-29, 1923. Alexander R. Craig, Chicago, Ill., Secretary.

July, 1923. Massachusetts Association of Boards of Health, July 26, Nantasket, W. H. Allen, Mansfield, Mass., Secretary.

*Deceased Sept. 2, 1923.

Address.

SOME PROBLEMS OF READJUSTMENT IN MEDICAL PRACTICE.*

BY W. B. CANNON, M.D., BOSTON.

It is altogether natural that the professionally trained person should find his chief satisfaction in the exercise of those functions which have been specially disciplined and prepared for a particular service. During the late war the medical officers assigned to an administrative job or given "paper work" to attend to were inclined to resent it or were impatient under it—they had had experience as physicians and surgeons and were eager to show their skill in the performance of professional tasks. And so it is with us in our relations to the people whom we serve. Ordinarily we feel that we are showing to a satisfactory degree our usefulness to society if we as members of the medical profession do our duty in caring for the sick.

Good reasons can be found for feeling a satisfaction in this attitude. The sick are in need, often in sore need, of what we have to give them. And there is much comfort not only for them but also for us in the beneficent results of intelligent medical and surgical care. The intimate personal relations between doctor and patient have a sameness and a grace which bring forth the rarest fruits of friendship. That it is argued, is the natural work for us physicians, the

work for the individual, for the man or woman or child who is ill or who is broken and who needs us.

THE WIDENING OF PROFESSIONAL INTERESTS.

There are other relations, however, which exist between us and our communities which we are prone to overlook in the very intensity and keenness of our devotion to professional service. We are physicians, to be sure, but we are also citizens. And as citizens we not only have, I believe, the routine duties of citizenship, but also obligations to the public at large, due to our special knowledge of matters which are of interest and of vital importance to our fellows. Many years ago, when I was a medical student, I recall a short address which the late Professor W. T. Sedgwick made to a small group of us, in which he urged that we were justified in working intensively on strictly professional lines until we reach the age of 35 or 40, but that thereafter we ought to set aside at least one day each week for public service. His own career was a splendid example of disinterested usefulness in public affairs, and the advice he gave was emphasized by his own accomplishments. What he urged upon us then, I wish to urge today—a broadening of the sense of professional duty, a realization of the general needs of our communities that are quite as critical and should be quite as appealing to our professional conscience as the individual needs to which we traditionally limit our attention. The motive for this wider range of action is the same motive that serves

*An Address to the graduating class of the College of Physicians, June, 1921.

for the narrower one—the opportunity for service. And the reason why we should feel the potency of this motive is likewise the same for both—a special knowledge, which we possess and which renders us peculiarly serviceable citizens.

The evidence of community need for the kind of intelligence which physicians possess is found in various relatively new understandings of the sources of misery and sickness and of the unhappy consequences which flow from them.

THE IMPORTANCE OF ATTACKING DISEASE-PRODUCING CONDITIONS.

Social studies have revealed that considerable groups of our population are involved in the vicious circle of miseries—poverty and ignorance leading to unhygienic living; unhygienic living leading to ill health and physical inefficiency; these in turn leading to unemployment and further poverty. And so the round of wretchedness continues. Is it not clear that the circle is not strategically well attacked at the stage of sickness, the stage at which we as conventional practitioners of the art of healing are called in? No, the point where the circle should be broken is at the earlier stage of ignorance and unhygienic living. The broadening of our professional services would lead us to increase our influence at that point, where there is chance for preventing the more dangerous events of the cycle.

Again, industrial hygiene has demonstrated the existence of a web of lines on every side connecting the individual with his fellows and with the part he plays in the complex of modern industry. Thus the use of measures to reduce the incidence of sickness and injury of working men has been shown to yield a wide variety of benefits. The worker himself is saved the economic loss which arises both from being out of work and from having extra unnecessary expense. Those who are dependent on him are protected from slipping into the vicious circle of poverty and disease which is an ever-present possibility. And further, industry also is protected from the disturbances and needless costs that ensue when workers must constantly be replaced. All these values are obtained when attention is paid, not to the sick, but to the well, with the object of keeping them well.

Better than anything else the experience with certain infectious diseases has proved, and proved overwhelmingly, the advantages to mankind of medical knowledge applied to groups with the purpose of preventing disease rather than to individuals with the purpose of curing them. The sanitary measures which have been employed to eradicate hookworm and yellow fever, malignant malaria and typhoid are a sufficient witness to the possibilities of improving the physical welfare of vast populations through the services of preventive medicine. Who will set a limit to further developments by methods and in directions suggested by these triumphs? Have we

not the right to hope that with wider diffusion of knowledge and with the general awakening of intelligence as to the nature and spread of infections, other devastating diseases will likewise be suppressed?

The lesson of these experiences we as a profession have been too slow in learning. Too long we have been on the defensive in the fight against sickness and premature death. Too tardily have we accepted the military doctrine that the best mode of defence is to attack. Only in recent years have we begun to realize that it is part of our professional service to do our best to eliminate the conditions which lead to the physical distress and damage and the economic inefficiency of our fellows.

There is no question of the urgency of the need for professional medical service outside the sick-room. It has been estimated that in our country every fifty seconds a person dies from preventable disease. That means the appalling number of more than 630,000 such deaths annually. Think of the pain and bereavement and the awful waste of life that that huge figure implies! And in economic terms it is equally astounding. It has been estimated that unnecessary sickness and premature death is costing the United States every year more than two billion dollars. Yet to a great degree these evils are due to ignorance and can be abolished by knowledge and by conduct based on knowledge. There is little doubt that large masses of our population are a full generation behind what the medical profession knows is desirable in the practices of personal hygiene and in the avoidance of disease by employment of preventive measures.

The reason should now be clear why we as physicians have public as well as personal services to perform if we are to do our full duties as citizens. If we were living in an autocracy, we could influence high authority and have benefits wrought by edict. But we live in a democracy, where education must take the place of paternalism, and the people must win their own benefits through knowledge and intelligent action. Because of the social ramifications of disease, therefore, we are finding imposed upon us a new sense of social responsibility and an obligation to use our professional knowledge for the welfare of the group as much as for the individual.

PUBLIC EDUCATION AS A MEANS OF DISEASE PREVENTION.

Already an organized movement in the direction of public education has been started. Eleven years ago there was established in the American Medical Association a Council on Health and Public Instruction. From the start it has had as one of its objects the spreading of information among our people regarding the great advances in scientific medical knowledge during the past fifty years and the possibility

of using that knowledge for the prevention of disease, the reduction of the death rate and the promotion of healthier living. Let me tell you of some of the activities of the Council in this aspect of its work.

One of the first things we did was to organize a speakers' bureau. After securing promise of the services, in all parts of the country, of competent physicians, capable of talking with interest and authority on questions of personal and public health, we sent a list of the speakers to about 20,000 Women's Clubs. A pamphlet was prepared describing to local groups the methods which had been found most effective for holding a successful meeting. Speaker's handbooks were assembled, giving in brief compass reliable information which could be added, when thought desirable, to any theme which the speaker intended to develop. Standard sets of stereopticon slides were prepared for temporary loan wherever they might prove serviceable. By these means meetings were arranged all over the United States, and thousands of people were reached.

Another method for diffusing informative matter was through use of daily and weekly journals. For many years a printed sheet containing news items or topics of medical interest was sent regularly to papers throughout the land. The editors soon became convinced that our motive was disinterested public service and had no ulterior intent. More and more this material was used for news purposes and as a text for editorial comment. No doubt through these channels, hundreds of thousands of our population have had opportunity to learn of the most recent advances in medicine.

Still another activity of the Council has been the publication of a series of standard pamphlets for wide distribution. These have been written by the best available authorities. For example, the pamphlet on Tuberculosis was prepared by Dr. E. R. Baldwin, so long associated with Dr. Trudeau at Saranac; that on Typhoid Fever by Professor E. O. Jordan of the University of Chicago; that on Hookworm by Dr. J. A. Farrell of the Rockefeller International Health Board; the pamphlet on Flies as Disease Carriers by L. O. Howard, the well-known entomologist; and that on Pure Water by Professor G. C. Whipple of Harvard University, an expert sanitary engineer. Some of our publications have had a very extensive use. In one year more than 300,000 copies of Dr. Emmett Holt's pamphlet on the Care of the Baby were sent broadcast to mothers by a firm selling babies' blankets! And the Department of Education of the United States Government made use of 750,000 copies of the little publication on the Sanitary Requirements of a Rural School.

A Subcommittee of the Council, on the Conservation of Vision, brought out the fact that in our country the dependent blind cost approximately \$15,000,000 annually. It was estimated

that nearly 80 per cent. of this blindness was preventable if only people had better knowledge of the causes of blindness and exercised due caution based on that knowledge. Admirable pamphlets on the hygiene of the eye and protection of the eye against damage, written by experts, have been prepared and are being used by speakers, and by others, for teaching purposes.

Another Subcommittee of the Council which has done excellent service is that on Public Health Education Among Women. This aspect of the organization was testimony to the fact that much of the work for public health is in its essentials nothing more than good house-keeping, applied on a large scale. It was realized that already in many cities the principles of cleanliness, neatness and good order had been insisted upon by women's organizations and that the public spirit which prompted these activities could be counted upon in other efforts to promote the happy chances of life. Representative women physicians have served on this Committee and have been effective intermediaries between the organized medical profession and the natural interest of lay women in establishing circumstances favorable to better health.

In this connection another great public-spirited body should be mentioned—the Women's Foundation for Health. This is a federation of 14 national women's organizations, having a total membership of 10,000,000. Its aim is to push an aggressive campaign for the attainment of vigorous health by women. According to its enquiries, out of 100 girls examined only 10 are really well. Another 10 need to go to a doctor or a dentist or surgeon for curative or corrective attention. The remaining 80 of the 100 are suffering from three to eight symptoms which keep them below par—symptoms which are the result, not of disease, but of faulty health habits. These figures can readily be credited when we realize that the examination of an enormously large number of men in the draft revealed that from 33 to 50 per cent. of them were unfit for service, because of physical or mental defects. The object of the Women's Foundation, then, is to strive, not for health as the negation of disease, but for positive health, a degree of health that is attended by vigor and energy and fitness for all the stresses that life may bring. In the Foundation, as one of the constituent members, is the Medical Women's National Organization.

Besides these activities we have seen develop nation-wide campaigns against tuberculosis and venereal disease, public efforts in many places to lower the rate of infant mortality, an extensive home-nursing service instituted by the American Red Cross, and the spread into ever-enlarging fields of State and national health functions.

What does this strange evolution in medicine imply? Where does the general practitioner fit into these new relations which are aris-

ing between voluntary or professional health organizations and the public? What attitude shall the individual physician take towards attempts to improve the health of our people by lectures and classes and organized propaganda?

THE DOCTOR AS A PROMOTER OF PERSONAL HEALTH.

There is, I believe, an unfortunate tendency among us to try to draw a sharp distinction between the preventive and the curative aspects of medical service. The preventive work, it is said, should be restricted to State and national agencies or to voluntary organizations composed largely of laymen. And the practice of curative medicine should be solely the service of the private practitioner. As a matter of fact, it is difficult to separate definitely these two aspects of medical activity. The curative treatment of the insane and the delinquent is unhesitatingly admitted to be a State function. And when treatment is the means of prevention, as in the case of smallpox, for example, again the community, not the individual physician, becomes responsible for the patient's care. On the other hand, the private practitioner called to a case of typhoid fever, for example, at once has the duty thrust upon him of warning the whole community of the danger, and setting at work all the machinery for discovering and cleaning out the source of infection. Obviously there are overlapping areas in the application of preventive and curative measures that do not permit hard and fast boundaries to be drawn. In the common territory it appears that the agents of preventive medicine have been encroaching or threatening to encroach on what have been regarded as the privileges of curative medicine. Bitter resentments have thus been aroused, and in consequence societies have passed strong resolutions denouncing what is designated "State medicine" and calling a halt in its further progress. The conflict which has thus arisen is concerned with the theme we have been considering and may properly be discussed in relation to it.
